INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—The following list of special subjects is to be considered at the seventh International Congress of Hygiene and Demography (Section VI., Architecture in Relation to Hygiene), which will be held in London from the 10th to the 17th of August next:—1, Laying out and extension of towns, including the control of the construction of buildings and the reservation of open spaces; 2, Planning and construction of dwelling-houses, especially common lodging-houses, workmen's dwellings, and residential flats; 3, Hospitals for infectious diseases; 4, Construction and arrangements of asylums; 5, Sanitation of theatres and public halls. The meetings of the above Section will be held in Burlington House, Piccadilly, London, on the 11th, 12th, 13th, and 14th of August. Abstracts of all papers to oe read in the Section must be furnished to Mr. Ernest Turner, honorary secretary, 246, Regent Street, W., not later than the 15th of June, and the full text of the papers before the 30th of June. Abstracts of papers should not exceed 500 words, and should be type-written, to ensure accuracy in printing and translation. Papers and abstracts may be written, and speeches in the meetings delivered, in French, German, and English, No paper will be received which has been previously published or communicated to any other society. A limit of fifteen minutes will be fixed for a paper or speech introducing a subject, and a limit of ten minutes for all subsequent speeches or papers on the same subject. All communications relative to this Section should be addressed to Mr. Ernest Turner, 246, Regent Street, W. In matters relating to the general business of the Congress letters should be addressed to the Honorary Secretary-General, 20, Hanover Square, W.

ROYAL AGRICULTURAL SOCIETY.—At the Warwick meeting of the above Society, to be held next year, prizes for ploughs, divided in the following classes, will be offered:—Class 1, for the best single furrow plough for light land; 2, for the best single furrow plough for strong land; 3, for the single furrow plough best adapted for a press drill and broadcast sowing; 4, for the best two-furrow plough; 5, for the best three-furrow plough; 6, for the best digging plough for light land; 7, for the best digging plough for heavy land; and 8, for the best one-way plough. Entries for the competition are to be made to the Royal Agricultural Society, 12, Hanover Square, London, before the 25th July next.

THE ROYAL INSTITUTION.—Under the title "The Artificial Production of Cold," Mr. H. Graham Harris, M.Inst.C.E., commenced, on the 9th inst., a course of three lectures on the principles and various kinds of machines for ice-making and the production and maintenance of low atmospheric temperatures. He wished first to make clear the physical principles which were the basis of all the different kinds of machines for producing, and appliances for maintaining, cold. "Production of cold" was another term for "abstraction of heat," but it was a popular one, and, though not scientifically accurate, he had used it. The transference of heat from one body to another was, in some form or other, under our daily notice. To produce cold we had to take advantage of some way of transferring heat from where we did not want it. It would be requisite to speak of heat in measureable quantities, and the standard commonly used was the British unit of heat. After alluding to Joule's well-known mechanical theory of heat, the lecturer mentioned the different methods for producing heat, and dwelling on the production of it by compression, especially in gases, showed that the converse—*i.e.*, expansion—was accompanied by loss of heat—that was, the production of cold. Though heat could be removed by conduction, it was mainly on the principle that heat was lost in expansion that most cooling appliances were based.

BUSINESS ANNOUNCEMENT.—Messrs. Cole, Marchent, & Morley, engineers, of Bradford, have appointed Mr. Wilson Hartnell, of 11, Queen Victoria Street, London, E.C., as their agent for all classes of general engineering and oil mill machinery. Messrs. James Lee & Sons, leather belting manufacturers, of Hipperholme, near Halifax, have also appointed Mr. Hartnell as their agent for their best leather belting and Lee's patent link belting.

MANCHESTER, 14th May, 1891.

MANCHESTER ASSOCIATION OF ENGINEERS.—A party of members of the above Association paid a visit, on the 11th inst., to the mill belonging to the Astley Spinning Company, Ld., at Dukinfield, for the purpose of inspecting the large engines made by Messrs. Goodfellow & Matthews, which have been fully described in these columns (see *Industries*, Vol. II., page 396). The makers have recently applied a compensating arrangement to the governors, by which the position of the tripping pieces applied to the high-pressure cylinder are varied according to the velocity of the governor, and the running of the engine is thus steadied. The condition of the driving ropes was closely scrutinised in view of a discussion which took place on this subject about two years ago at one of the meetings of the Association. These ropes are running about 5,800ft. per minute, and have not been replaced during the six years the mill has been working. The interior arrangements of the mill are very good, a noticeable feature being in the card room, where the machines are arranged so that the sliver cans have not to be carried long distances from the carding engines to the drawing and slubbing machines. The labour involved is thus reduced to a minimum. The mules, containing 1,052 spindles each, run across the room, and a pair of them, or 2,100 spindles, are attended by a spinner and two piecers. Each of the floors above the first is 10in. wider than the one below, owing to the difference in the thickness of the walls.

THE ENGINEERING TRADES.—Engineers are, generally speaking, still well supplied with work. There is not much falling off in the supply of orders, although in the Continental markets there is hardly so much activity. An experiment is being conducted at a mill in the town with forced draught applied to an ordinary Lancashire boiler, and the results, although not yet finally formulated, have on the whole been satisfactory. Machine tool makers continue to be very busy, and are receiving plenty of orders. There is little of special interest to report in this department, as makers are actively engaged on their standard patterns. Cotton machinists are very busy, the amount of work in this department showing no signs of diminution. A number of new engineering works are being erected in the vicinity of the Manchester docks of the Ship Canal, the Unbreakable Pulley Company having nearly completed a large shop for the manufacture of pulleys and shafting. Another industry which is assuming large proportions is the manufacture of miners' safety lamps, two concerns in this district being now at work manufacturing special descriptions of lamps which contain improvements on the older types.

THE LINEN AND JUTE TRADES.—As Whitsuntide approaches there has been an increased demand from retailers, but, with regard to linens, the position of manufacturers has been rendered less satisfactory on account of the diminution in the demand from the United States, the Spanish West Indies, Australia, and other important outlets abroad. A remarkable fact in connection with the shipping business is that while the Plate district is not absorbing the usual quantity of linens, in exports of which there has been a serious decline, purchases of the cheaper jute fabrics have increased, which shows that owing to financial depression the one material is wherever possible being substituted for the other. There is an increase of business with Brazil, both Yorkshire and Irish firms having received better orders from local exporters. Prices keep steady. Manufacturers are placed in a somewhat awkward position by the continued firmness of yarns. Brown cloth has not advanced proportionately with the increased prices demanded by spinners, and finished goods have failed to keep pace with the upward movement in unbleached linens. Buyers here have these facts pointed out frequently, but they are slow to respond to the wishes of sellers.

IMPROVED DUST GRID.—We have recently inspected the action of a new application to the dust trunks used in connection with cotton openers, which is likely to be of great service where dirty cotton is used for spinning, such as Indian and American. The dust trunks are ⌂ shaped as ordinarily made, and a series of chambers are formed on the flat portion of the tube. Placed in a zig-zag direction around the curved portion of the tube castings are fixed by riveting. The castings are formed with downwardly projecting teeth, which catch the cotton as it is drawn along the tube by the air current and tend to open and cleanse it. As a space is left between the fixings the cotton passes through the gap, and about a foot further on another casting is fixed so as to catch the cotton which goes through the gap untouched. The effect is that the cotton receives a check periodically as it travels along the tube, and is opened considerably, much more dirt being shaken out. An examination of the droppings removed from the tubes shows that a much larger proportion of dirt and a less amount of fibre is eliminated than is the case with dust trunks of the usual construction.

GLASGOW, 14th May, 1891.

PIG IRON.—The sharp rise in the prices of pig iron is due to the extensive "bear" operations having left the operators in possession of a heavily oversold account. There is no change in the condition of trade which justifies this sudden rise. When the speculators in the South begin to "unload" the market will probably drop as sharply as it has risen. There are now 60 furnaces in blast against four at the beginning of the year, and against 87 at this date last year.

SHIPBUILDING.—At the present time there is no vessel on the stocks at Fairfield, and in the other yards, as a rule, there are no important orders. The "Napier of Magdala," which has been built by Messrs. Hawthorne, of Leith, for the use of the Clyde Submarine Mining Volunteers, was tried in the Forth on the 9th inst., prior to being sent round to the Clyde *vid* the Caledonian Canal. The establishment at Fort Matilda, where the "Napier of Magdala" will be stationed, is now very extensive. From this point a complete system of torpedo defences for the Clyde is controlled. The ramifications of the lines of defence extend down the firth for a considerable distance, and thoroughly command the passage between Fort Matilda and Roseneath shore. Messrs. Wm. Hamilton & Co., Port Glasgow, have contracted with Messrs. W. & J. Crawford, Greenock, to build a steel sailing ship of 2,000 tons register.

ENGINEERING.—Messrs. James Neilson & Son, Alma Boiler Works, Gallowgate, have just brought out a new boiler. The idea is originally American, and the first boilers constructed by the firm have been made to the order of an American firm. In general appearance the boiler is like the locomotive type. Before passing through a system of sixty-eight tubes 3¼in. in diameter, the heated gases pass through two tubes 15in. in diameter and one tube 4¼in. in diameter.

ELECTRIC PHOSPHORUS.—Dr. Readman at the May meeting of the Society of Chemical Industry gave a description of the new works and plant which have been erected at Wolverhampton for the manufacture of phosphorus by the Readman-Parker patents. The process consists in decomposing the mixture of phosphoric acid, or acid phosphates and carbon, by the heat of the electric arc imbedded in the mass, and the inventors urge that the local application of heat in this form is more economical than the heating of large retorts containing the mixture as in the ordinary process. Further details and results of the new process are promised at an early date.

LAUNCH OF THE "LORD OF THE ISLES."—The well-known steamer "Lord of the Isles," which sailed in the summer season between Wemyss Bay and Inverary, having been sold to the Victoria Steamboat Association for service on the Thames, the "Lord of the Isles" Company determined to build another steamer of similar character for service on the same route. This vessel has been built by Messrs. D. & W. Henderson & Co., Meadowside, Partick, and was launched on the 25th ult. The new "Lord of the Isles" is a paddle steamer of 450 tons, is 255ft. in length, 25ft. 6in. in breadth, and 8ft. 6in. in depth. The speed is expected to exceed that of the older vessel, which, at the speed of 20 miles per hour, accomplished the journey to Inverary and back—a distance of nearly 230 miles—easily in a day. The engines will be supplied by the builders, and will be of design similar to those constructed for the original "Lord of the Isles."

CLYDE FIRMS AND THE PORT OF LA PLATA.—It is announced that a syndicate has been formed to take over and work on lease the port of La Plata from the Provincial Government of Buenos Ayres. If any arrangement can be made which will place the trade of the port and the finances of the Government on a more satisfactory basis than is the case at present, very considerable advantage will accrue to many Clyde firms, who have large and, at present, unremunerative interests in the Argentine.

(*From our own Correspondents.*)

LIVERPOOL, 13th May, 1891.

THE LIVERPOOL ENGINEERING SOCIETY.—At a meeting of this Society on the 6th inst., the discussion on the paper of Mr. George Farren, on the "Denudations at Aber-Menai," was resumed. Some remarks were made upon the geological formation of the bank which forms a natural breakwater at the entrance to the Menai Straits, and the general opinion of the members appeared to be that to protect the bank from further destruction it should be protected, not by a large vertical monolithic breakwater, but by protected slopes, which would tend to break the waves. The excursions during the coming summer were arranged, and it was decided to visit the works of the Manchester new waterworks, different places of interest in Birmingham, the Dore and Chinley Railway now in course of construction, and the North Wales Slate Quarries.

THE LIVERPOOL UNIVERSITY COLLEGE.—At a meeting of the governors of the University College here, it was announced that several munificent gifts had recently been made to the college, amongst which we may mention £10,000 by J. T. Brunner, M.P., to endow a Chair of Economic Science, and £1,000 by Mr. Ludwig Mond, for the encouragement of the higher studies in chemistry.

INCRUSTATION IN BOILERS.—Messrs. Macdonald & Co., of 3, Wapping, Liverpool, are introducing a new composition, called the Bretel Vegetable Boiler Fluid, to prevent incrustation and corrosion in boilers. Numerous advantages are claimed for this composition, which, judging from the number of testimonials we have seen, would appear to be generally realised.

ELECTRIC LIGHTING AT SOUTHPORT.—The new theatre in course of erection at Southport is to be lighted by electricity. The generating plant in connection with the

Digitized by Google

Winter Gardens will supply the current. About 220 lamps from 8 to 300 c.p. will be installed, and fittings of artistic design used throughout. Arrangements for obtaining various degrees of illumination for stage purposes will be made to be under the control of the light man. The contract has been placed with the Manchester Edison-Swan Company.

SHEFFIELD, 13th May, 1891.

The Iron and Steel Market.—There is a slightly firmer tone in the iron market this week. The price of hematites has risen about 1s. to 2s. per ton, and has been followed to a certain extent by ordinary merchant and foundry pig iron, which have lately been sold at less than cost price. Few new orders are reported in the steel casting trades beyond the usual amount of orders for locomotives and small material. This depression in the cast steel branches may be accounted for by the fact that nearly all the contracts for material required for engineering purposes under the naval programme have been awarded. There is still a very fair demand for railway material for the home railways. The Glasgow and South-Western are inviting tenders for five hundred sets of wheels and axles; the Midland continue to give out orders which are divided amongst the Lancashire, Yorkshire, and Staffordshire makers. Colonial orders are generally rather scarce, but some have been received from India. Prices are now as follow: Locomotive tyres, £13; waggon tyres, £10 to £12; Siemens or Bessemer axles, £10 to £11; springs, guaranteed by makers, £10. Billets and small bars vary in price, according to quality, from £5 to £10. Tool steel of the best qualities still maintains a good price, from £80 to £100 per ton.

Coal and Coke.—The demand for fuel of all kinds is brisk, and colliers are working full time. No reduction of price is contemplated, and the miners say they will resist any reduction in wages. Coke is steady, and the best qualities fully maintain their value.

Society of Chemical Industry.—A meeting of members of the Society of Chemical Industry and other influential persons was recently held in Leeds, in order to consider the formation of a Yorkshire Section of the Society. It was stated that the Society was founded in 1881, and at the present time numbers 2,500 members, being the largest Chemical Society but one in the world. Sections of the Society were already formed at many of the most important centres of chemical industry. Professor Smithells, in moving a resolution in favour of the object of the meeting, said that there were already about 125 members of the Society resident in Yorkshire. The resolution was carried unanimously, and Sir James Kitson, Bart., was elected Chairman of the Section. Information as to membership may be obtained from Mr. C. H. Bothamley, at the Yorkshire College.

Miners' Eyesight and Safety Lamps.—A very interesting correspondence is taking place between Mr. Court, the miners' surgeon connected with the Staveley works, and Dr. Simon Snell, ophthalmic surgeon to the Sheffield Infirmary, regarding the prevalence of "nystagmus" among miners where safety lamps are used. Dr. Snell is to publish his observations in book form shortly.

NORTH STAFFORDSHIRE, 13th May, 1891.

The Iron Trade.—At the adjourned meeting of the local blast furnace proprietors and their employés, held on the 8th inst., a reduction in wages of 7½ per cent. was amicably arranged. At present the firmer prices of Scotch warrants have exercised no influence on sales here, and where makers have advanced their prices buyers have declined to purchase. The demand for puddle mine and furnace mine has fallen off, and prices are now 13s. per ton for the former and 9s. per ton for the latter.

The Pottery Trade.—The arbitration to settle the wages dispute in this trade commenced yesterday at Stoke-on-Trent. The tribunal consists of three arbitrators—Mr. H. T. Hinckes, M.P., appointed by the Arbitration Board; Mr. B Stuart, of Ironbridge, appointed by the Manufacturers' Association; and Mr. J. Mawdesley, of Manchester, chosen by the operatives. Mr. W. Owen, operatives' secretary, conducts their case, and Mr. H. T. Buddam, barrister-at-law, the masters' case.

CARDIFF, 13th May, 1891.

Iron and Steel.—The firmer tone in the hematite iron trade continues. The decrease in the output has undoubtedly been a factor in improving the position of the market, and ironmasters show no disposition to relight the idle furnaces. Spanish ore continues high in price on account of a restricted supply during the year, together with the fact that arrivals of tonnage at Bilbao and other loading ports have been plentiful. Several large contracts for Rubio ore have been concluded for delivery in the Bristol Channel, at prices ranging from 13s. 6d. to 13s. 9d. c.i.f. Cardiff and Newport for 50 per cent. iron. There have been a few inquiries for steel rails, but no orders of importance have been given out. The demand for steel tinplate bars (Bessemer) has fallen off considerably on account of the proposed stop week in the tinplate trade. Quotations are nominally £5 12s. 6d., but this figure is difficult to obtain.

Coal and Coke.—Exports of steam coal continue heavy, and notwithstanding the usual monthly holiday last week the shipments reach a total of 264,706 tons. Inquiries for forward delivery are not so numerous, but on account of the low outward freights an extra quantity is being shipped to the depôts in the Mediterranean and East. Steam coal sells at—1st quality, 14s. 6d. to 14s. 9d.; 2nd, 13s. 9d. to 14s. 3d.; 3rd, 13s. to 13s. 6d.; and 4th, 12s. 6d. to 12s. 9d.

Terrible Explosion at Newport.—A terrible explosion occurred at Newport on the 11th inst. on the steamship "Tancarville," which resulted in the loss of five lives and injuries to a dozen men. This vessel, which was an iron ship with a tonnage of 1,541 tons, and was engaged in carrying crude petroleum in tanks between Philadelphia and Havre, was undergoing repairs in Messrs. Mordey, Carney, & Co.'s dry dockyard. The explosion occurred at 10 a.m. in the fore part of the vessel, where eight men out of seventy employed in repairing the vessel were riveting in a tank. Five of these men were killed, and the iron decks, bulwarks, and hatchways were torn asunder, and parts of them hurled to a distance of 200 yards. It has been suggested that the explosion was caused through the dangerous gases arising from the oil becoming ignited by the heated rivets, which were being fixed by the men in the tank. The damage done to the ship has been estimated at £8,000 to £10,000.

BARROW-IN-FURNESS, 13th May, 1891.

Hematite.—There is a steadier and more active tone in the hematite pig iron trade this week, and more business is being done all round. Not only are makers selling more largely, but stocks of hematite warrants have again been reduced to the extent of 6,576 tons, leaving still in the stores 155,609 tons. This is a large amount, but compares favourably with 380,000 tons in stock in the beginning of 1890. The sales during the week have been at the average of 50s. net cash for warrant iron, and makers have been disposing of Bessemer mixed numbers at 51s. 6d. net f.o.b. Thirty-nine furnaces are still in blast, and thirty-eight are standing idle.—A boring is about to be made in a new district near Gosforth, to the south of Egremont. Some borings were made in this district several years ago, but no ore was then discovered.

Steel.—Business in the steel trade is fairly good in the Bessemer department, but no new orders of importance are being received for Siemens-Martins qualities of steel. Heavy rails are quoted at £4 11s. 6d., and light rails at £5 10s., with £6 10s. for colliery sections. Further developments are being made in the Siemens-Martins department, and new rolling mills and powerful engines are being put down for this purpose. In steel castings and hoops a brisk trade is being done, but orders for blooms, billets, slabs, and tinplate bars are quiet.—During the week ending on the 9th inst. the largest output of Bessemer steel since the Moss Bay Works were first started has been recorded. These works made a total of 325 blows, or a total of 2,764 tons of ingots, this being done in one pit only. The steel rail mill, notwithstanding a half-day's stoppage, rolled 2,530 tons of rails during the week.

Iron Ore.—Orders for iron ore are comparatively few, and stocks of ore have accumulated at the mines. Prices are easier, at 10s. per ton net at mines for ordinary qualities.

MIDDLESBROUGH, 13th May, 1891.

Pig Iron.—Little business was done at the weekly iron market yesterday, though prices were well maintained. For prompt f.o.b. deliveries of No. 3 G.M.B. Cleveland pig 39s. 6d. per ton was quoted both by makers and merchants, but buyers would not offer more than 39s. 3d., and for summer delivery 39s. Makers are not pressing sales, because, with extra demands from the Continent and the large deliveries to Scotland, they are reducing their stocks at a good rate. Middlesbrough warrants are 39s. 9d. cash buyers, and 40s. cash sellers. The stock in Connal's store on the 11th inst. was 116,965 tons, a decrease this month of 1,334 tons. No. 4 foundry and No. 4 forge pigs are going in large quantities to Scotland, and the prices are firm. The former is quoted at from 38s. 3d. to 38s. 6d., and the latter at from 37s. 9d. to 38s. per ton. Local hematite is obtainable at from 50s. to 51s. per ton for mixed numbers.

Manufactured Iron and Steel.—The finished iron and steel trades are very dull, and in some cases prices are weaker. Iron ship angles are £5 7s. 6d; iron bars, £5 10s. to £5 15s.; iron ship plates, £5 10s. to £5 12s. 6d; steel ship plates, £6; steel angles, £5 15s., all less 2½ per cent. for cash on the 10th of month following delivery. Heavy steel rails are £4 10s. net at works.

Shipbuilding.—A new shipyard is to be established on the Port Clarence side of the Tees by the Haverton Hill Shipbuilding Company, which has been formed with a capital of £100,000. About ten acres of land have been acquired in a bend of the river. The land is at the proper level for launching vessels, and the ground is firm enough to carry heavy weights. It is within convenient distance of the various ironworks. The frontage allows of stocks being laid down for the simultaneous construction of from six to eight vessels of from 4,000 to 5,000 tons burthen. There will also be a repairing department. With the exception of the Tees Conservancy Dry Dock, and the slipway at the Cleveland Dockyard, there are now few facilities for repairs of the largest type of vessels in the Tees, and most of the repairing work goes to the Tyne. This department will probably be the first to be put into active operation, and there will soon be an addition of some 2,000 men to the working population.

SUNDERLAND, 13th May, 1891.

Shipbuilding and Engineering.—Orders for new vessels are scarce. Messrs. John Blumer & Co., North Docks, have, however, secured another contract for a sailing ship. The question of overtime continues to be discussed, but no definite agreement has as yet been arrived at.

Shipping.—The freight market has, on the whole, become more depressed. Outward rates are unremunerative, and at the same time terms for loading are very difficult to arrange. It is a matter of surprise that steamship owners do not send their vessels in ballast to the homeward loading ports, seeing how great is the detention and how small the outward freights. Prompt homeward business is fairly satisfactory, but for forward fixtures lower rates are offered. The local coal shipments continue to be more satisfactory, 71,970 tons being shipped last week, and 81,970 tons in the preceding week. The general import and export trade does not, however, improve.

Marine Engineers' Union.—The general council of this Union met here on the 8th and 9th inst. The revision of the constitution of the Union was the principal subject of discussion, and this work is to be continued at an adjourned meeting to be held here. It is stated that fully one-half of the membership of the Union consists of marine engineers located in the North-East Coast district.

NEWCASTLE, 13th May, 1891.

The Coal Trade.—The activity in the local coal trade has been further stimulated this week by the anxiety of shippers to get cargoes despatched before the pits are stopped for the Whitsuntide holidays. Work at the shipping staiths is consequently very busy, and more steamers are awaiting "turns" than are likely to receive cargoes this week. The demand for household coals has, as is usual at this season, fallen off. The general briskness of the industry is largely attributable to the greatly increased foreign demand for steam and gas coals. The shipments of coal and coke at Tyne Dock during the week ending the 9th inst. amounted to 118,033 tons, being a decrease as compared with the shipments for the corresponding week last year of 2,905 tons.

New Company.—The prospectus of Messrs. W. B Reid & Co., Ld., of the Leases Brewery, Newcastle, has been issued, the share capital being £150,000, in 15,000 ordinary shares of £10 each, and the mortgage debenture capital £150,000, in five per cent. mortgage debentures. Of the mortgage debentures £120,000 are issued to the public, the remaining £30,000 being retained by the vendor. Applications for these debentures will be received up to the 16th inst. The ordinary shares are not issued to the public.

Shipping.—Since the beginning of the month a few of the steamers that had been laid up since January or February have again found employment, and it is probable that others will be withdrawn from the mooring berths shortly. Although there does not appear to be, as yet, any very marked increase in the shipping business, the outlook has improved, and shipowners are more hopeful of getting steadier employment for their vessels and more remunerative rates of freight. Messrs. Newman & Dale, of London and Newcastle, have sold to an Austrian firm their steamer "Apex," and have purchased from a firm of Spanish owners a comparatively new vessel of large size. Messrs. Palmer's Iron and Shipbuilding Company launched, on the 9th inst., a splendid vessel named the "Francesco Crispi," ordered by the recently formed Italo-Britanico Steam Navigation Company, Ld., and Messrs. Swan & Hunter launched, on the 11th inst., a 7,000-ton cargo boat named the "Cundall," ordered by Mr. C. Furness, of West Hartlepool.

The Timber Trade.—Most of the sawmills are busy just now, as there is a large amount of building being done. The imports of pit props and sawn timber are daily becoming more numerous, and an appearance of greater animation is consequently presented at the docks.

Engineering.—The Tyne Pontoon and Dry Dock Company, Ld., of Wallsend, have given out the order for the construction of another and larger pontoon than the one which they have hitherto possessed. The pontoon in question will be 300ft. in length and 70ft. broad, and will be capable of lifting vessels up to 320ft. or 330ft. long. The pumping apparatus is to be of a very powerful nature, and will consist of four 15in. centrifugal pumps, each driven by a separate engine, and the whole supplied with steam by two large multitubular boilers. The order for this pontoon has been secured by Messrs. C. S. Swan & Hunter.

North-East Coast Institution of Engineers and Shipbuilders.—At a meeting of this Institution, held on the 11th inst., under the presidency of Mr. Wigham Richardson, Mr. W. Hök replied to the discussion on his paper, "The Unsinkability of Cargo-carrying Vessels." Mr. Harry Gray also replied to his paper on "Water Gauge Fittings for Steam Boilers." The Chairman, referring to Mr. J. Petree's paper on "The Basis of Ships' Scantlings," said that a point had been raised with respect to the disadvantages of English shipowners as compared with foreign owners. He pointed out the injustice of foreign owners being allowed to set the load-line at defiance. Though a ship might be built in England and placed under load-line rule, it was allowed either in foreign waters or English waters to carry more weight than an English vessel.

(*For description see page* 460.)

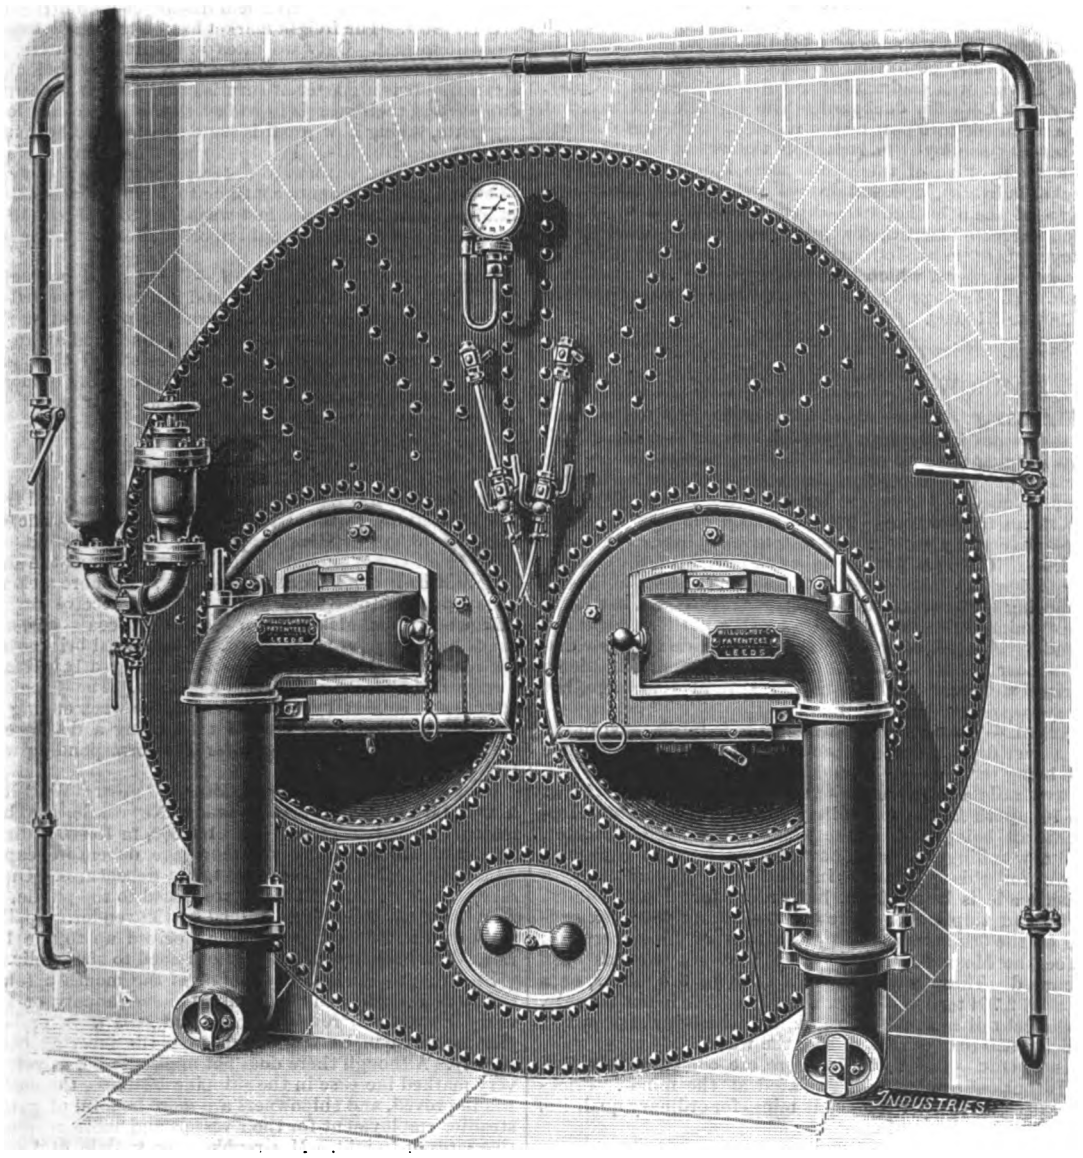

FIG. 3.—FRONT VIEW OF BOILER AND APPARATUS.

CLYDE SHIPBUILDING FOR APRIL.

THE paucity of inquiries for new vessels is becoming a matter of concern in certain districts, and has given rise to the opinion that over-building is taking place. It is, doubtless, that builders are at present experiencing a greater difficulty in securing orders than they were, and if anything like a moderate briskness is to prevail throughout the remainder of the year new work should be immediately forthcoming, the more especially as the Government work now in hand is being rapidly advanced, and the large vessels under construction for established lines are nearing completion. In the Govan district especially matters wear a very sombre aspect. During each month since January the output of tonnage largely exceeded the amount of new work booked, and for the month under consideration the former exceeded the latter by at least 24,000 tons. Of the new orders Messrs. Russell & Co., of Port Glasgow and Greenock, secured the lion's share, they having received instructions to build two sailing ships, one of 2,000 tons, for a Liverpool house, and the other, of 1,660 tons, for a London firm. Messrs. Blackwood & Gordon also received an order for a steel twin-screw steamer of 1,000 tons for the Ceylon trade of a London firm.

The output of 32,177 tons was made up of 20 steamers and 11 sailing vessels. To this aggregate Messrs. R. Napier & Sons, Govan, contributed 8,420 tons, while Messrs. Russell & Co. launched six vessels with a total tonnage of 6,680 tons. The most important vessel put into the water was the magnificent twin-screw steamer "Ophir," of 6,700 tons and 11,000 h.p., constructed by Messrs. Robert Napier & Sons for the Orient Steam Navigation Company. Her principal dimensions are:—Length, 482ft.; breadth, 53ft.; and depth, 37ft. She has been built to meet the Admiralty requirements for armed cruisers, and is specially designed for the mail service between London and Australia. She is fitted with two sets of triple-expansion engines to develop sufficient power for a speed of 18 knots. Great interest is being centred in this vessel, as she in many respects resembles the "Scot," now nearing completion at the Leven shipyard of Messrs. William Denny & Bros., Dumbarton. Among other vessels launched there were six saloon paddle-steamers, principal among which were the "St. Tudno," built by the Fairfield Shipbuilding and Engineering Company, Govan, for passenger service between Liverpool, Llandudno, and Beaumaris and the "Lord of the Isles," built by Messrs. D. & W. Henderson & Co., Partick, for service between Glasgow and Inverary. The former vessel is of 900 tons gross register, and measures 277ft. in length by 32ft. 6in. in breadth, while the latter is 22ft. shorter, with a beam of 25ft. 6in.

The following are the particulars of the vessels launched:—

SINGLE-SCREW STEAMERS.

"Brio," steel, 1,850 tons, built by the Campbeltown Shipbuilding Company, and fitted with triple-expansion engines by Messrs. Kincaid & Co., Greenock, for Messrs. Fenwick & Reay, Newcastle-on-Tyne.

"Clan MacKinnon," steel, 2,450 tons, built and fitted with triple-expansion engines by Messrs. Alexander Stephen & Sons, Linthouse, to the order of Messrs. Cayzer, Irvine, & Co., for the Clan Line of steamers.

Hopper barge, steel, 300 tons, 250 h.p., built and engined by Messrs. William Simons & Co., Renfrew, to the order of the Preston Corporation.

"Madeira," steel, 330 tons, built by Messrs. Russell & Co., Port Glasgow, and fitted with triple-expansion engines by Messrs. Kincaid & Co., Greenock, to the order of the Amazon Steam Navigation Company.

"Mira," steel, 1,000 tons, 1,200 h.p., built and fitted with triple-expansion engines by Messrs. A. & J. Inglis, Pointhouse, to the order of the Bergenske Dampskibselsbab, of Bergen, Norway, for the Norwegian Coast touring service.

"Moth," iron, 150 tons, trawler, built by Messrs. Mackie & Thomson, Govan, and fitted with compound engines by Messrs. Muir & Houston, Kinning Park, for the North Sea fishing trade of the British Steam Trawling Company, Hull.

"Rattler," sister ship to the "Moth," by the same builders, for the same owners.

"Scott-Harley," steel, 450 tons, built and engined by Messrs. John Fullerton & Co., Paisley, for the general trade of Messrs. Scott, Harley, & Co., Cork.

"Suzanne et Marie," steel, 1,600 tons, 2,000 tons deadweight capacity, 1,200 h.p., built and fitted with triple-expansion engines by Messrs. Lobnitz & Co., Renfrew, for the French and foreign trade of Messrs. Wirms, Josse, & Co., Havre.

TWIN-SCREW STEAMERS.

"Chilian," steel, 1,720 tons, built and fitted with triple-expansion engines by Messrs. Robert Napier & Sons, Govan, for the Pacific coasting trade of the Compania Sud Americana de Vapores, Valparaiso.

"Ophir," steel, 6,700 tons, 11,000 h.p., built and fitted with triple-expansion engines by Messrs. Robert Napier & Sons, to the order of the Orient Steam Navigation Company, for their Australian service.

PADDLE STEAMERS.

"Fairy Queen," steel, 300 tons, built by Messrs. T. B. Seath & Co Rutherglen, and fitted with compound surface-condensing engines by Messrs. Davies & Co., Paisley, to the order of the Mona Steamship Company, for the Isle of Man passenger traffic.

"Lord of the Isles," steel, 450 tons, built and fitted with triple-expansion engines by Messrs. D. & W. Henderson, Partick, for the Glasgow and Inverary Steamboat Company.

"Marchioness of Lorne," steel, 450 tons, built by Messrs. Russell & Co., Port Glasgow, and fitted with triple-expansion engines by Messrs. Rankin & Blackmore, Greenock, to the order of the Caledonian Steam Packet Company, for passenger service on the Clyde.

"Ravenswood," steel, 400 tons, built by Messrs. S. M'Knight & Co., Ayr, and fitted with compound surface-condensing engines by Messrs. Hutson & Corbett, Glasgow, for Messrs. P. & A. Campbell, for service between Bristol and Tenby.

"St. Tudno," steel, 900 tons, built and fitted with compound surface-condensing engines by the Fairfield Shipbuilding and Engineering Company, Govan, for the Liverpool and North Wales Steamship Company.

"Woolwich Belle," steel, 400 tons, built and fitted with compound surface-condensing engines by Messrs. William Denny & Bros., Dumbarton, for the Thames passenger traffic of the London, Woolwich, and Clacton-on-Sea Steamboat Company.

SAILING VESSELS.

"Alexander Block," steel barque, 1,400 tons, built by Messrs. A. MacMillan & Sons, Dumbarton, for Mr. William Mitchell, Londonderry.

"Ancois," steel, 1,700 tons, built by Messrs. Russell & Co., Greenock, to the order of Mr. G. Soley, Liverpool.

"Belmont," steel, 1,450 tons, 2,450 tons deadweight capacity, built by Messrs. Russell & Co., Port Glasgow, to the order of Mr. J. G. Hall, Boston.

"Collessie," steel, 1,300 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Messrs. Gray, Macfarlane, & Co., Glasgow.

"Invercauld," steel, 1,300 tons, built by Messrs. A. MacMillan & Sons, Dumbarton, to the order of Messrs. George Milne & Co., Aberdeen.

"Lucknow," steel, 1,400 tons, built by Messrs. Charles Connell & Co., Scotstoun, to the order of Messrs. W. & J. Crawford, Greenock.

"Mount Stewart," steel, 1,900 tons, built by Messrs. Barclay, Curle, & Co., Whiteinch, to the order of Messrs. Donaldson, Rose, & Co., Aberdeen.

"Senegal," steel, 1,400 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Mr. G. M. Steeves, Liverpool.

YACHTS.

"Dragon," composite cutter yacht, 14 tons, built by Messrs. W. Fyfe & Sons, Fairlie, to the order of Mr. F. Hall, Ardrishaig.

"Herione," steam yacht, 320 tons, 1,000 h.p., built and fitted with quadruple-expansion engines by Messrs. Fleming & Ferguson, Paisley, to the order of Messrs. J. & A. Allan, Glasgow.

"Mira," steam yacht, 320 tons, designed by Mr. G. L. Watson, Glasgow, and built and engined by Messrs. D. & J. Dunlop, Port Glasgow, to the order of the Hon. F. G. Wynn, Carnarvon.

Steam yacht, 14 tons, 40 h.p., built and engined by Messrs. Hanna, Donald, & Wilson, Paisley.

In addition to the above Messrs. Hanna, Donald, & Wilson built two composite vessels each of 23 tons for foreign owners.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 15TH MAY, 1891.

THE IRON AND STEEL INDUSTRIES OF AMERICA.

THE remarks made by Sir James Kitson at the recent meeting of the Iron and Steel Institute, regarding the iron and steel industries of America, were, on the whole, not calculated to raise the spirits of his audience. The trade with which his hearers are concerned has passed through a short period of great activity and prosperity, and there is before it another period, possibly longer than the previous one, if not of stagnation, at least of scarcity of work. Engineering, in all its departments, is experiencing the beginning of a time of depression, while shipbuilding is rapidly falling off. Both in engineering and shipbuilding the years 1889 and 1890 must rank very high in the industrial annals of the United Kingdom, not only on account of the amount of work produced, but also because of the large returns made to employers and employed. Were it not for another fact dwelt upon by Sir James Kitson we might almost be inclined to accept with reasonably good grace what seems to be inevitable with our present system of industry—namely, alternate periods of great activity and of greater depression. But, as Sir James Kitson pointed out, the relative industrial position of Great Britain is rapidly changing, and in the future our manufacturers will have to contend with forces which until recently were either unknown or were so weak as to be left out of account in discounting the immediate future of any department of industry. He stated that the recent visit of the members of the Institute to America had shown them that the resources of that continent were inexhaustible, and whether under a system of Protection or of Free Trade, the United States was, in his opinion, a country bound to develop these resources, and to become, in the course of that expansion, a great manufacturer of iron and steel. The American furnaces were producing a larger quantity of iron than we produced in this country, but there were compensations in practice in our greater economy of production and in the better quality of our materials. If, perhaps, one word of warning was needed, it was in regard to the important point of the price of fuel. In the United States fuel was abundant and accessible, and coal and coke in the iron districts were lower in price, more accessible, and of equal quality to the fuel obtained in this country. It, therefore, appeared to him that those at home, both producers and workmen, who had the control here of the cost of fuel, ought to pause in their demands in view of the unlimited resources of America. No doubt it is true that American industries are hampered by high wages and want of economy, but even making allowance for all this we must expect a great expansion of the manufacture of iron and steel on the other side of the Atlantic, which will not only supply the wants of the countries situated there, but also compete with us in the other markets of the world. Sir James Kitson has enlarged on some of the points involved in an article in the *Contemporary Review*, in which he gives notes of the visit of the Iron and Steel Institute to America last year. We will not enter into the details of travel or of hospitality, but, in view of the importance of the subject, will mention a few of the industrial and economic conditions which are likely to affect the problem.

One feature which struck the English visitors was the fact that the American skilled artisan puts forth more physical effort and produces more work in a given time than the English workman or the workman of any other manufacturing community, and this conclusion was verified by observations in various parts of America. The productive power of American workmen is greater than that of English workmen in the same time. Their working hours are longer, but their remuneration is greater. The workmen in America, however, recognise that the extreme physical effort put forth sape the vital energies and cuts short the career—in short, they understand that continual work at high pressure does not pay in the end. This remark applies with equal force to the employers and to the employed. Competition between manufacturers is keener than in this country, and this fierce competition reacts on the men. The visitors were surprised to find in a democratic country like America that the workmen had so little power, and were to such a large extent the docile instruments of energetic employers. The foremen and managers of factories drive the men to an extent that employers would never dream of attempting in this country, and the trade unions do not seem able to protect the men in this respect. American manufacturers thus get the greatest possible service out of their plant. These facts have important bearings on the question of international competition. Another noteworthy matter is the number of ingenious mechanical labour-saving devices employed.

The immense natural resources of the country were evident at every point. In the neighbourhood of Pittsburg, the metropolis of the American iron industry, there was everywhere evidence of marvellous mineral wealth. The coal crops out on the flanks of the hills and the banks of the rivers. The seams are in many places 10ft. thick and upwards, and the coalfield is estimated to extend to an area of 1,400 square miles. Petroleum and natural gas are obtained in abundance, and add immensely to the manufacturing facilities of the district. Of the former, the State of Pennsylvania produces 250,000 barrels per month, and it has a yearly output of 30,000,000 tons of bituminous coal, and last year produced within a small fraction of one-half of all the pig iron, and more than one-half of all the rolled iron and steel made in the country. In the Pittsburg district alone 750,000,000ft. of natural gas are delivered to consumers each day through 1,125 miles of pipe, for the use of mills and factories, and to upwards of 30,000 warehouses, stores, hotels, and dwelling-houses. Pittsburg's 21 blast furnaces in 1889 produced 1,203,435 tons of pig iron, while 33 rolling mills showed a production of 1,105,573 tons of steel, and 638,450 of rolled iron. Its 49 iron foundries represent a capital of over £2,000,000 sterling, its 15,000 coke ovens yield 9,000,000 tons of coke, used in the manufacture of pig iron. It is the leading centre for the production of steel rails. At the Edgar-Thomson steel works the visitors saw blast furnace plant which was the most complete and advanced in the United States, one furnace having the remarkable output of 2,300 tons of pig iron per week. The only fuel used

Digitized by Google

for heating the furnaces and the boilers is natural gas. The employers of Pittsburg are men who are directly engaged in the management of their own businesses, and seemed for the most part to have risen to the head of establishments by their natural skill and business aptitude. They are exceptionally active, energetic, and full of resource and enterprise, and are mainly practical rather than scientific men. It will, however, be found that many of the younger men who are responsible for the scientific work have for the most part passed through the course of study of one of the numerous technical schools which have been established in America during recent years. Altogether the impression produced on the visitors by Pittsburg was that, with its immense natural resources, and the activity and intelligence of those who manage its works, that city is able to compete with any manufacturing city in the world. Sir James Kitson thinks that with such extroadinary advantages as its manufacturers possess their industrial position is impregnable, without the artificial barriers which they take so much pains to set up around them.

The English visitors were also much impressed with the energy and activity, and the consequent phenomenal development, of Chicago. Its varied interests make its people less strongly in favour of Protection than are the people of such a district as that of Pittsburg. The President of the Iron and Steel Institute at one of the receptions given in its honour ventured to speak in favour of Free Trade, and his observations were received with warm approval by the members of the Chicago Corporation. It was evident that a fear existed that the European market for Chicago products might be interfered with if the policy of the McKinley Tariff Act was persisted in. That Act seems to have been specially framed to stop the export of tinplates from England and Wales to the United States, which is now the only business of great amount and value between those countries. The present business in tinplates with the United States amounts to 6¼ million boxes per annum, weighing about 400,000 tons. The duty paid under the old tariff was £4 10s. per ton; under the new tariff it is about £9 17s. per ton, so that the increased cost of duty on tinplates will amount to £2,140,000, and the total duty to £3,940,000. If the duty on tinplates should be maintained the Americans will doubtless, in due course of time, make all their own tinplates. The question will then arise whether the farmers and artisans of the United States will be content to pay a high price for canned goods and domestic utensils, for which tinplates are largely used, simply in order to put money into the pockets of a few manufacturers.

It was found that the manufacturers of the South held different opinions on fiscal questions from the people of Pennsylvania, and that in many cases they were very pronounced in favour of Free Trade. The Southern States have made great developments in industry and trade during the past dozen years, and are now able to strive against their Northern competitors. The manufacturers of the Southern States believe that, with their abundant resources and cheapness of production, they can hold their own against all competitors without the aid of Protective duties. Sir James Kitson gives some interesting details of his observations in the Southern States, but into these we have not time to enter. He concludes by asking what are the leading characteristics of those who are engaged in the chief industries. He answers that these are quickness to adopt improvements, and readiness to adopt scientific methods in the processes of manufacture. He points out that in the departments of iron and steel manufacture, great as has been the industrial growth of America, marvellous as are the mechanical achievements of Americans, we can still claim that the inventions which have brought the manufacture of iron and steel to its present state of perfection are of English origin. The Americans have not invented, they have improved. Sir James Kitson says that the high standard of education, and especially of technical education, of the people of America undoubtedly is much to their advantage. He recognised everywhere a promptness to discard old plant and an alertness to adopt the newest and the most scientific methods of production. He thinks, however, that there need be no ground for apprehension as to the competition of the United States. Our insular position, our abundant supply of labour, our accessibility to mineral products, make it, in his opinion, certain that England, as a producer of iron and steel, will continue to hold the leading place in the neutral markets of the world. On the whole, we are inclined to agree with this opinion, but we can afford to neglect neither the education of our workmen and managers, nor any mechanical improvements which may lead to increased economy and efficiency.

POSTAL REFORM AND THE DECIMAL SYSTEM.

On the 8th inst. an influential deputation from the Associated Chambers of Commerce and the Decimal Association was received by the Chancellor of the Exchequer and the Postmaster-General, with reference to certain proposed reforms in the Postal Service, and to the introduction of the decimal system as regards weights and measures. Colonel Hill, M.P., President of the Associated Chambers of Commerce, introduced the deputation, which included Sir A. Rollit, M.P., Mr. Shaw-Lefevre, M.P., Mr. C. H. Wilson, M.P., Mr. William Leng, M.P., Dr. Farquharson, M.P., Mr. O. Morgan, M.P., Mr. S. Montagu, M.P., Mr. A. Illingworth, M.P., Mr. H. S. Wright, M.P., Mr. Arnold Morley, M.P., Sir E. Harland, M.P., Sir Vincent K. Barrington, Sir William Thomson, F.R.S., Sir G. L. Molesworth, Sir Philip Magnus, Major Campbell Johnston, Mr. J. W. Menzies, R.A., Mr. Rowletts, Professor H. S. Foxwell, Mr. F. Hendriks, and representatives of the more important Chambers of Commerce. Colonel Hill said that the deputation wished to bring under the notice of Ministers four subjects—first, the application of the surplus of the Post Office revenue above a certain sum to the improvement of the postal service; secondly, the establishment of an Imperial penny postage, which was estimated to cost about £75,000; thirdly, a reduction in the cost of telegrams; and fourthly, the introduction of the metric system of weights and measures as the first stage in the adoption of a complete decimal system. Mr. Shaw-Lefevre, M.P., advocated that the excess of the postal revenue above £3,000,000 should be devoted to the giving of increased postal facilities.

Mr. Goschen, in reply, said that the Post Office authorities were willing to carry out necessary reforms in the service, and the Treasury did not wish to hamper them in their endeavours. A large expenditure, however, must yet be incurred in the buying of sites and the construction of buildings in large provincial towns, which had been made necessary by the increased business of the Post Office. The introduction of Imperial penny postage would involve a loss of more than £75,000. Although, in consequence of the new system of 2½d. postage, the weight of letters carried during the first four months of 1891 had increased by 14·24 per cent. over the weight carried during the corresponding months of 1890, the revenue received from the carriage of those letters had decreased by 43·6 per cent. The penny rate would probably involve a considerable loss unless the letters were carried by slow ocean steamers. With regard to the telegraphs, he would prefer to extend the telegraph system to localities which would not pay rather than to diminish the cost of telegrams. Representatives from this country would attend the Postal Convention which was about to be held at Vienna. In reply to Mr. S. Montagu, M.P., Sir William Thomson, Mr. J. E. Dowson, and Mr. A. Smith, who advocated the introduction of the decimal system of weights and measures, Mr. Goschen said that such a change would confuse for a time the transactions of almost everybody in the country, and he could not recommend the Government to appoint a Royal Commission on the subject. He admitted that the reform would be attended with great advantages, but much present inconvenience would have to be borne in effecting the change advocated.

H.M.S. "SAPPHO."

The above vessel was launched from Messrs. Samuda's building yard at Poplar on the 9th inst. The "Sappho" is a steel twin-screw armour-protected cruiser similar to the "Apollo" and others of that class, and is one of the ships ordered under the new Naval Defence Act of 1889. Her dimensions are:—Length, between the perpendiculars, 300ft.; breadth, extreme, 43ft.; mean draught of water, 16ft. 6in.; displacement, 3,400 tons; indicated horse-power, 9,000; estimated speed, 20 knots. The hull is built entirely of Siemens steel, and is divided into numerous watertight compartments. The stem and stern post—the former of which is fitted with a powerful ram, being strengthened by a strong prow-plate going some 15ft. into the vessel—are formed of steel castings. The engines, boilers, magazines, and all the vital parts of the ship are protected by a 2in. steel deck running the whole length of the vessel, and above this deck is an armoured breastwork of 5in. compound armour-plates and 7in. teak backing protecting the cylinders. The engines, which are by Messrs. John Penn & Sons, of Greenwich, are of the triple-expansion type, with inverted cylinders, and with large boiler capacity. The armament consists of two 6in. quick-firing guns, six 4·7in. quick-firing guns, eight 6-pounder guns, one 3-pounder gun, one 9-pounder field gun, four ·45 Nordenfeldt guns, making in all twenty-two guns, besides which she has four 14in. Whitehead torpedo guns. She has also an armour-plated conning tower on the forecastle, and a steel torpedo director tower on the poop. The ship, when launched, had nearly all her fittings on board, the masts and all the rigging up, and all the auxiliary machinery in place and fixed. Her sister ship, the "Scylla," will shortly be ready for launching from Messrs. Samuda Brothers' yard.

THE GERMAN EXHIBITION.

On the 9th inst. there was opened at Earl's Court a German Exhibition, which is the fifth of a series of Exhibitions which have been organised by Mr. J. R. Whitley. The object of the Exhibition is to illustrate the arts, inventions, manufactures, products, and resources of Germany. The exhibits have been selected exclusively by a German Committee, and represent the most important branches of German industry. The main gallery of the Exhibition has been divided into eleven groups, in each of which the objects belonging to a particular department are arranged. This is a decided improvement on the arrangement at the previous Exhibitions at Earl's Court, when the exhibits were scattered about on stalls with no systematic attempt at order. The great feature of the German Exhibition will, however, be the extensive exhibit of German paintings. The Exhibition will be open until October next.

COAL, IRON AND COGNATE INDUSTRIES.

The Board of Trade Returns for the month of April, and the four months then ended, have been issued, and, so far as the general trade of the country is concerned, are of a satisfactory character.

For the month there is an increase in the exports of £574,699, and in the imports of £3,302,295, as compared with the corresponding period of last year. For the four months there is a decrease in the exports of £194,989, and an increase in the imports of £202,931. The figures relating to the coal industry indicate a continued activity in the export trade, which cannot fail to be gratifying to those collieries situated at or near the sea board, and at which both proprietors and employés are reaping a rich harvest. To those connected with the iron and steel works of the country it will be no surprise to find from the published statistics a great diminution in the exports relating to those industries. The total amount of iron and steel exported for the month amounted to 287,422 tons, valued at £2,612,179, a falling off of 17 per cent. in quantity and 4 per cent. in value; for the four months the decrease is 21 per cent. in quantity, and 10 per cent. in value.

We append our usual tabular statement:—

	Month of April.		Four Months.	
	1891.	1890.	1891.	1890.
Pig and puddled	£165,308	£405,426	£518,978	£1,180,432
Bar, angle, &c.....	143,059	143,589	503,924	522,497
Railroad.....	337,646	477,555	1,219,876	2,112,897
Cast and wrought ...	452,273	533,477	1,639,684	2,055,633
Unwrought steel.....	324,737	272,172	1,135,703	1,182,889
Unwrought copper ...	204,506	179,854	754,508	749,165
Coals, &c.	1,674,513	1,460,978	5,799,157	5,620,664

Turning to the home markets, the experience of the trade for the past month has been far from encouraging. On the one hand, the cost of production has not been materially reduced, while on the other, prices have continued on a downward grade. Since January the price of pig iron has fallen about 5s. per ton, that of bar iron 10s. per ton. The relative position of cost and prices is actually worse than it was in 1888, when the depression in trade reached its lowest level. In many instances ironworks are being carried on at an absolute loss to the proprietors, and there are not wanting

Digitized by Google

cases where works have been brought to a standstill. The immediate outlook cannot be regarded with any great amount of hopefulness. Though the "bulls" on the Glasgow warrant market are at present in the ascendant, and though stocks are being heavily drawn upon, there does not appear any substantial basis for the anticipation of a boom in prices. The abnormal continuance of cold weather during the last month has caused the demand for house coal to be maintained, but as the summer approaches less fuel will be used and prices will exhibit a weaker tendency. Already competition for the supply of manufacturing coals has become very keen in all land-locked centres, and prices are generally lower.

TIMBER PILING IN FOUNDATIONS AND OTHER WORKS.

A PAPER having the above title was read before the Society of Architects, on the 12th inst., by Mr. Henry Adams, M.Inst.C.E. The paper was divided into several heads, and was illustrated by many carefully drawn diagrams and well-selected specimens. First treating of the woods used in piling, the author described all the more commom forms: their weight, their method of growth, the manner in which they are imported, and their cost. Then, dealing with the preparation of the materials, he described the process of creosoting, and then, more particularly, the method of pointing and driving the piles for various works. A description of the different methods of pile driving was then given, and careful consideration was given to the supporting power of timber piles. This the author considers to depend upon three circumstances — (1) the resistance of the point to further penetration; (2) the friction of the earth against the sides of the pile; and (3) the strength of that portion of the pile rising above the ground considered as a column. The first two of these cases are generally combined into one formula, founded entirely upon experiments.

The author gave and compared the formulæ of Major Saunders, McAlpine, Weisbach, Rankine, W. K. Clark, Bidder, Brereton, and Lieutenant Sankey, and also a Dutch rule quoted by Molesworth and the results of experiments made by Kircaldy. Dobson's rule was then considered. The author drew attention to the fact that if the distance through which the head of the pile moves after being struck be considered as the criterion of the resulting force in pounds, this assumption is not true, as only part of the force is returnable as supporting power, some of it being expended in compressing the pile. The author concluded his paper by referring to some well-known examples of the use of piles in foundations, mainly taken from work on the banks of the Thames.

Letters to the Editor.

THE NICARAGUA CANAL.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Referring to my former letter on the subject of the Nicaragua Canal, it will interest your readers to know that Mr. Miller, the president of that undertaking, has returned from Nicaragua, and is thoroughly satisfied of the entire feasibility of the plans for the canal, and has no doubts about its ultimate success. He further believes that the cost will be less than estimated, all the work hitherto having been executed at prices below those estimated by the engineers.

The Suez Canal caused a revolution, not only in shipbuilding and marine engineering, but also in the methods and conditions of commerce. The completion of the Nicaraguan Canal will also have far-reaching effects. These, on the whole, will be felt in America to a greater extent than in this country, but it cannot be doubted that they will also be felt here to a very considerable extent. The length of the Nicaraguan route is somewhat greater than that of the other routes which have been proposed, but few now fail to see that, although it is burdened with locks, it is more practical, far less costly, and more useful than any of the others, and will accomplish the same object. The canal would practically double the present available coast line of North America by connecting the Eastern and Western States, and would again increase their trade by giving a shorter route to other countries. At present sailing vessels trading between San Francisco and New York are compelled to pass around Cape Horn, a distance of 19,000 miles. The immense produce of the Pacific coast can now only be transported to the Atlantic States by 3,000 miles of railway or by the long voyage round South America, so that the entire value of these productions is often consumed in the expense of the journey.

There cannot be the slightest doubt that the completion of the canal will give the manufacturers of the United States an immense hold on the trade of South America, and a great, or at least considerable, advantage over those of Britain, and it thus introduces a new factor in the ever-increasing competition of the world. American politicians recognise most distinctly that by the completion of the canal the community of interests between the American States would be enormously strengthened. Those of the United States say that the South American Republics are patterned after theirs, and that there can be no clashing of interests between them. For many years they are not likely to be manufacturing countries, but will be devoted mainly to agriculture and mining. They will naturally exchange their gold, silver, sugar, coffee, tropical fruits, grain, and other sources of wealth for the manufactures and productions of the United States.

The trade of this country, in its relations to the East especially, will be profoundly affected. A new and shorter route will be opened to China and Japan, and no doubt part of the traffic which at present goes by the Suez Canal will be diverted to the Nicaraguan, although the growth of the trade may be sufficient to prevent the change from resulting in any great degree in a financial loss.

I certainly think your journal is doing useful service in directing attention to some of the wider aspects of the questions under consideration. Very often questions connected with education, industry, and commerce are looked at in too restricted a manner, and the remote and indirect effects are often lost sight of in looking too closely at those immediately under consideration.

Yours, &c.,

Liverpool, 11th May, 1891. C.E.

SIMPSON'S TRAIN INDICATOR.

TO THE EDITOR OF "INDUSTRIES."

SIR,—In your issue of the 24th ult. you give an illustration of this indicator, and state that it can be made single or double faced, but from the details of the working arrangements I conclude that only the oscillating shutters can be made double-faced, and that the time of departure of the trains can only be shown on one side. If my conclusion be correct, then I say that the indicator falls far short in detail of those which I have seen on the Lancashire and Yorkshire Railway stations at Bolton, Wigan, and Southport (Patent No. 3935 of 1890), because the time of departure and stations are shown on both sides, and the departure times of three trains are shown on both sides in one frame at the Bolton Station, whereas, according to your description, the Simpson indicator does not accomplish this unless two of them are placed back to back, which would be very costly. Those I refer to are fitted with a glass-fronted case, in which the departures of all trains are recorded. In addition to this there are hands pointing to the departure platforms. Indicators are, as you state, very convenient for the public, especially as they render unnecessary many inquiries from the railway officials. I may state that I have no interest in the invention to which I refer, but it would be interesting if you or some of your readers would furnish some particulars of the working and arrangement of Patent 3935 of 1890 for the information of the travelling public.

Yours, &c.,

Leeds, 9th May, 1891. TRAVELLER.

FOUCAULT CURRENTS IN DYNAMOS.

TO THE EDITOR OF "INDUSTRIES."

SIR,—From the article on "Foucault Currents in Dynamos," which appeared in your issue of the 8th inst., it would be inferred that the method of analysing armature losses, published in the *Electrician*, and partly explained at the Institution of Electrical Engineers, claims to be a new *experimental* method of determining those losses. Now, it can hardly be necessary to say that it is only a graphic construction for analysing losses measured by perfectly well-known experimental methods. If Mr. Mordey had plotted the torque, as measured by his dynamometer, instead of the power, he would have obtained a straight-line diagram, and quadratic equations, &c., would have been unnecessary. Of course, no single pair of observations can give an accurate result by either method unless the experiments are absolutely exact, but the advantages of graphic analysis when a number of points of observation are distributed about a straight line are enormous.

It seems to be assumed that the losses in the winding and in bearing friction cannot be determined separately by this method. This, of course, is true if only the machine to be tested is used, but the use of a second motor is expressly mentioned, and this would take the place of Mr. Mordey's dynamometer. The second motor, however, should not be too small, otherwise its own losses are open to question. By this means friction may be observed at all speeds, or it may be eliminated entirely from the diagram. It is curious that Mr. Mordey shows it as constant, which, within the limits of speed generally used, seems to be very nearly true.

Variations of friction are sometimes troublesome with new bearings, but this is a difficulty which vanishes with patience.

With regard to the increased loss by Foucault currents on full load, this can hardly yet rank as an established fact; Dr. Hopkinson's classical experiments certainly show no indication of it. The neatest method of determining the point is to couple two similar machines Hopkinson-wise, and supply current directly to the pair in parallel. The power supplied then, of course, represents the sum of the losses in the two machines. I hope to be able to say more on this point shortly.

It may be mentioned that the graphic method of analysing armature losses was in use during the latter part of 1888, before Mr. Mordey had published his method.

Yours, &c,

R. H. HOUSMAN.

Birmingham, 12th May, 1891.

THE INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of this Institution, held on the 5th inst., the President being in the chair, a paper was read on "Railway Train Lighting," by Mr. William Langdon.

The author said that the desirability of a better illumination of railway carriages had been long felt. The lamps originally provided were intended simply to enable passengers to enter and leave the carriages without inconvenience, but the exigencies of the present time called for the additional luxury of a reading light. The illuminants in use were rape oil, paraffin oil, compressed gas, and electricity, and the author dealt with the recent advances which had been made in connection with the last.

In October, 1881, a Pullman car, running between Victoria and Brighton, was lighted by electricity, and the experiment was so far successful that it was extended to the entire train, and at present there were sixteen trains so lighted belonging to the Brighton Company. Mr. Houghton, the Company's electrician, and the late Mr. Stroudley, were the pioneers of the application of electricity to this purpose. An interesting experiment, devised by Mr. W. H. Preece, F.R.S., was tried on the London and South-Western Railway in 1883-4. The movement of the train was employed to compress air into a chamber, and the air so compressed was used to drive a dynamo to furnish the current for the lamps. In July, 1886, the Great Northern Railway applied electric light to one of their metropolitan trains. The Taff Vale and Cheshire lines had also made experiments in the same direction. In all these cases the lighting was effected by means of a dynamo driven from the axle of the guard's van combined with accumulators stored in the same vehicle. In August, 1884, the London and North-Western Railway tried a different principle in fitting up a short train which was still running between Manchester and Liverpool. The current was produced by a dynamo driven by a Brotherhood engine fixed to the tender and supplied with steam from the boiler of the locomotive. In this, however, as in the previous cases, the lighting was effected from one point, and should the train be broken up the part severed from the source of current would be left in darkness. In 1888, the directors of the Midland Railway authorised the equipment of two trains to run between London, Manchester, and Liverpool, in which the following conditions were to be fulfilled, viz.:—(1.) Each vehicle was to carry its own lighting power. (2.) Each vehicle was to be capable of being coupled and uncoupled and turned about as needed, without the possibility of the connections being wrongly made. (3.) The coupling must readily draw apart when coaches were slipped *en route*. (4.) The act of drawing the coupling apart must make all the changes in the connections necessary to transfer the lamps from the dynamo circuit of the train to the accumulator circuit of the carriage itself. (5.) Each compartment was to carry not less than two lamps. (6.) The lighting throughout the train was to be capable of being turned on or off from any one of the guard's vans. For the sake of experiment, one of these trains was equipped on the "Parallel" system, the other on the "Series" system. The former, having proved the best, had been adopted by the Company, and there were now five trains leaving St. Pancras daily which were electrically lighted, and in which the dynamo was driven off the axle of the guard's van, each vehicle being provided with accumulators capable of supplying the necessary current without the assistance of the dynamo. There was also a local train travelling between Manchester and Stockport, lighted after the plan adopted by Mr. Houghton on the Brighton Line, but equipped with two sets of accumulators and two dynamos driven from the axle. In addition to the foregoing, there were two trains running between London and Bedford, the dynamos of which were driven by small high-speed engines placed on the locomotive.

Dynamos.—In all cases where accumulators were employed, it was necessary (*a*) that the dynamo should automatically come into circuit when the requisite speed to enable the electromotive force of the machine to overcome the back electromotive force of the batteries had been attained. (*b.*) That the electromotive force should remain practically constant whatever might be the speed of the train. (*c.*) That the current should always be in one direction, whichever way the vehicle was running. The first trains fitted on the Midland Railway were furnished with machines giving a practically constant output of current, no matter how few or how many were the carriages attached. Messrs. Holmes & Co., of Newcastle, had since succeeded in making a dynamo which afforded a current proportional to the resistance of the circuit, and these machines were employed on all main line trains in which the dynamos were driven from the axle. Automatic apparatus effected the stipulated requirements.

Accumulators.—These were of the "E.P.S." type. With main line trains, where each vehicle carried its own batteries, the type employed was C 15 for the larger, and C 11 for the smaller carriages. In all cases the electrical pressure was 35 volts, so that 18 cells were necessary for each.

Electrical Coupling.—Where trains were not broken up, the difficulty of providing an efficient electrical coupling was not so great, but where the marshalling of carriages had to be smartly dealt with at terminal

Digitized by Google

or intermediate stations, the coupling must be such as not only to provide a good electrical connection, but to admit of easy handling. The form adopted by the Midland Company effected these objects in a perfectly satisfactory manner. On a coupling being separated, the lights were automatically turned on. If the lamps were not required, the coupling, instead of being allowed to hang down, was placed upon a "dummy," the effect of which was to turn the current off. For slip coaches special provision was made. By the insertion of a small resistance in each battery parallel, a fair distribution of the current throughout the different vehicles was attained, and in order to meet the increased pressure when the dynamo was in circuit, a sufficient additional resistance was automatically introduced. The lamps were of 8 candle-power, and there were two in each compartment, safety fuses being provided in connection with each group, as well as in connection with the dynamo itself. The circuits were arranged on the parallel system. With regard to the second mode of generating the current, namely, by dynamos placed on the locomotive, it was believed that at present no other trains save the three already referred to were equipped in that way. Mention should, however, be made of experiments conducted on the Lancashire and Yorkshire Railway in 1884, and also, in the same year, by Mr. W. H. Massey, on the Metropolitan District Railway. The extra staff required consisted, so far as the Midland Railway was concerned, of one senior officer and two train attendants at St. Pancras, one train attendant at Nottingham, Manchester, Bradford, and the services for about three hours per day of a man at Derby. The total number of electrically lighted vehicles now in operation on the Brighton, Great Northern, and Midland systems was 365 coaches and 57 vans.

In conclusion, the author pointed out that the main points to be determined were whether electricity was safe, reliable, and less costly than other illuminants. The fact that electrically lighted trains had now been running for a considerable period without accident would appear conclusive evidence of its safety, and experience had shown that there was no reason to doubt its reliability where efficient provision had been made; and the author believed that when the cost of applying any of the illuminants, whether oil, gas, or electricity, to a complete railway system was taken into account, that the latter would be found the most economical. The cost of oil was between ½d. and 1d. per lamp per hour. So far, compressed gas had never been employed for lighting the entire stock of any railway, with the exception of the Metropolitan Railway—which was specially adapted for its application. To consider the cost as applied to stock devoted to certain traffic would hardly afford a true basis of comparison. Where gas was used entirely, depôts must be established at each point at which trains were made up, whilst at busy centres it would probably have to be conveyed some distance by pipes laid down for the purpose. The cost of fitting coaches for gas varied from £4 8s. to £7 per lamp, while for electricity it was £50 for a six-bodied Midland main line coach, or £4 3s. 4d. per lamp. For trains running which were not broken up on the journey the cost per lamp amounted to £3 12s. or £18 per five-bodied coach. Vans with dynamos cost from £250 to £300 each. Statistics were given showing that the cost for maintenance in the case of gas was from ·045d. to ·250d. per light per hour. There was reason to believe that the total cost of compressed gas, when applied to an entire system, would exceed ½d. per lamp per hour, while the actual cost for electricity, as used on the Midland Railway, had not greatly exceeded ¼d. per lamp per hour.

Regarding electricity as the illuminant which would, at no distant date, be universally employed for train lighting, the author suggested the desirability of arriving at a common basis with regard to the following fundamental points:—(1.) Electrical system. (2.) Form and position of the electrical couplings. (3.) Pressure of current. Unless this was effected it was to be feared that unnecessary difficulties might be created by the diversity of the plans adopted.

THE INSTITUTE OF CHEMISTRY.

On Tuesday and Wednesday of this week the Fellows of the Institute of Chemistry held a conference at Burlington House, at which several Fellows had an opportunity of expressing their views as to the present position and future of their profession.

On Tuesday, Dr. Odling, F.R.S., of Oxford, opened the proceedings with an address "On the Relations of the Chemical Society to Professional Chemistry," in which he referred to the recent agitation as to the method of election to the Fellowship of the Chemical Society. He pointed out that the present system of admission being recommendatory it had been alleged that sparingly qualified and unsuitable candidates were elected by the present method of promiscuous election, and that this practice was objectionable on the grounds that it was derogatory to the Society, or detracting from the dignity of chemical science, and was also opposed to the interests of professional chemistry. He attached very little weight to the former of these objections, and proceeded to show that the function of the Chemical Society being the advancement of pure science it followed that it had no concern with the furtherance of professional interests. He pointed out, however, that the Council of the Society was composed of the most rising chemists, who were almost all either directly or indirectly interested in the profession, and that, therefore, although as a corporate body the Chemical Society could not recognise the profession, it was extremely unlikely that its policy was harmful to its interests. It must not be forgotten that there was a continuity in the policy of the Council, which had hitherto been conducive to the successful conduct of the affairs of the Society, and it must be admitted that the recent Jubilee celebrations were of such a character as to cause it to be patent that the Council of the Chemical Society had not failed to do its duty in emergencies. He proceeded to show that from a financial point of view it was expedient that the number of Fellows of the Chemical Society should be maintained, and that the remedy for the evil might consist of one of three measures—(1) A self-abnegatory announcement that Fellowship did not confer any attestation of scientific ability upon its holder; (2) The Council taking greater responsibility in the election of Fellows; (3) That the nominators should be responsible for the fitness of the candidates they propose. The first of these courses was impossible; the second would result in the Chemical Society's Fellowship being raised to a greater professional value, and would thus be antagonistic to the welfare of the Institute; whilst the last one he felt inclined to favour. He concluded by expressing his opinion that it was undesirable that the Fellowship of the Chemical Society should be considered tantamount in any degree to an attestation of scientific ability.

Several speakers followed, who defended the course of action of certain Fellows in their endeavour to induce the Council of the Chemical Society to take steps to secure that the Fellowship of the Chemical Society should be granted to those who would not derive a false position from such Fellowship, and who expressed regret that the foundation of the Institute had been found necessary, mainly owing to the neglect of the Chemical Society in the past to reconsider its position in respect to the chemical profession.

On Wednesday the proceedings were opened by Mr. Otto Hehner, who communicated a paper on "The Analytical Chemist in Relation to the Public, the Profession, and the Institute," in which he pointed out that chemists in this country might be divided into three groups, and that arranged in numerical order they stood as follows:—(1) Manufacturers; (2) analysts; (3) teachers. He contended that the Institute of Chemistry was founded for the second of these bodies, and that it was important for the public good that Fellows of the Institute should be recognised as qualified analytical chemists. Whereas long ago chemical analysis was practised as a branch of the science of chemistry it now afforded a means of livelihood to many men, and was of supreme public importance. In 1854 the London Directory contained the names of 11 analysts, in 1875 there were 20, and in the present year 98 names were inserted. The sudden growth between 1875 and 1881 was due to the passing of the Foods and Drugs Act, but sufficient time had now elapsed for the incompetent men to be weeded out from the profession by competition. The purely scientific chemist ignored commercial work in this country, but in Germany the two branches of the profession worked hand in hand, and had a similar status in the regard of the public. In early days analysis had been left to the tender mercies of microscopists, medical men, and agitators, but at the present time the exigencies of commerce required the modern analyst to be highly trained in his profession, and necessitated the utmost accuracy in all branches of commercial analysis. The subdivision of the work among specialists, who devoted their whole time to one branch of work, had further tended to increase the efficiency of the profession as a whole. Mr. Hehner then referred to the objects of the Institute as laid down in the charter, and pointed out, as we have already done in our recent articles on this subject, that the Institute was formed for maintaining the public efficiency of analysts and consulting chemists, and thus creating a body of men on whom the public can repose confidence and trust for reliable information on the purity or otherwise of articles of commerce. He then proceeded to show that hitherto the governing body of the Institute had consisted of men drawn from other branches of the profession than that for which he urged the Institute had primarily been founded, and advocated the admission to the Institute of all who could satisfy the examiners as to their analytical efficiency, irrespective of any enforced collegiate education. Professor Tilden, of Birmingham, the President of the Institute, expressed the opinion that it was erroneous to suppose that the professorial or teaching branch of the profession undervalued the analytical, and he believed that the majority of professors shared his view in this important matter.

Mr. Lloyd urged the desirability of taking the medical profession as a type of body which the Institute should try to imitate, and deprecated the unfortunate want of uniformity in the fees charged by analysts and chemical experts.

Mr. Blount, whilst agreeing with Mr. Hehner, suggested that the censors appointed by the Council had already the power to regulate and work towards the furtherance of many of the wishes expressed by previous speakers.

Mr. Allen pointed out that local authorities were unaware that Somerset House was, officially, only a referee as to matters included in the Foods and Drugs Act, and that, therefore, the competition of the Government in matters of reference with members of the profession was an anomaly. He felt sure that local authorities and public bodies would be willing to employ Fellows of the Institute as referees when it was known that the duties of Somerset House as referees were confined to the carrying out of this Act.

Dr. James Bell, F.R.S., announced that the sending of waters to Somerset House was being discontinued, and none were now received except those which had already been analysed by a Fellow of the Institute.

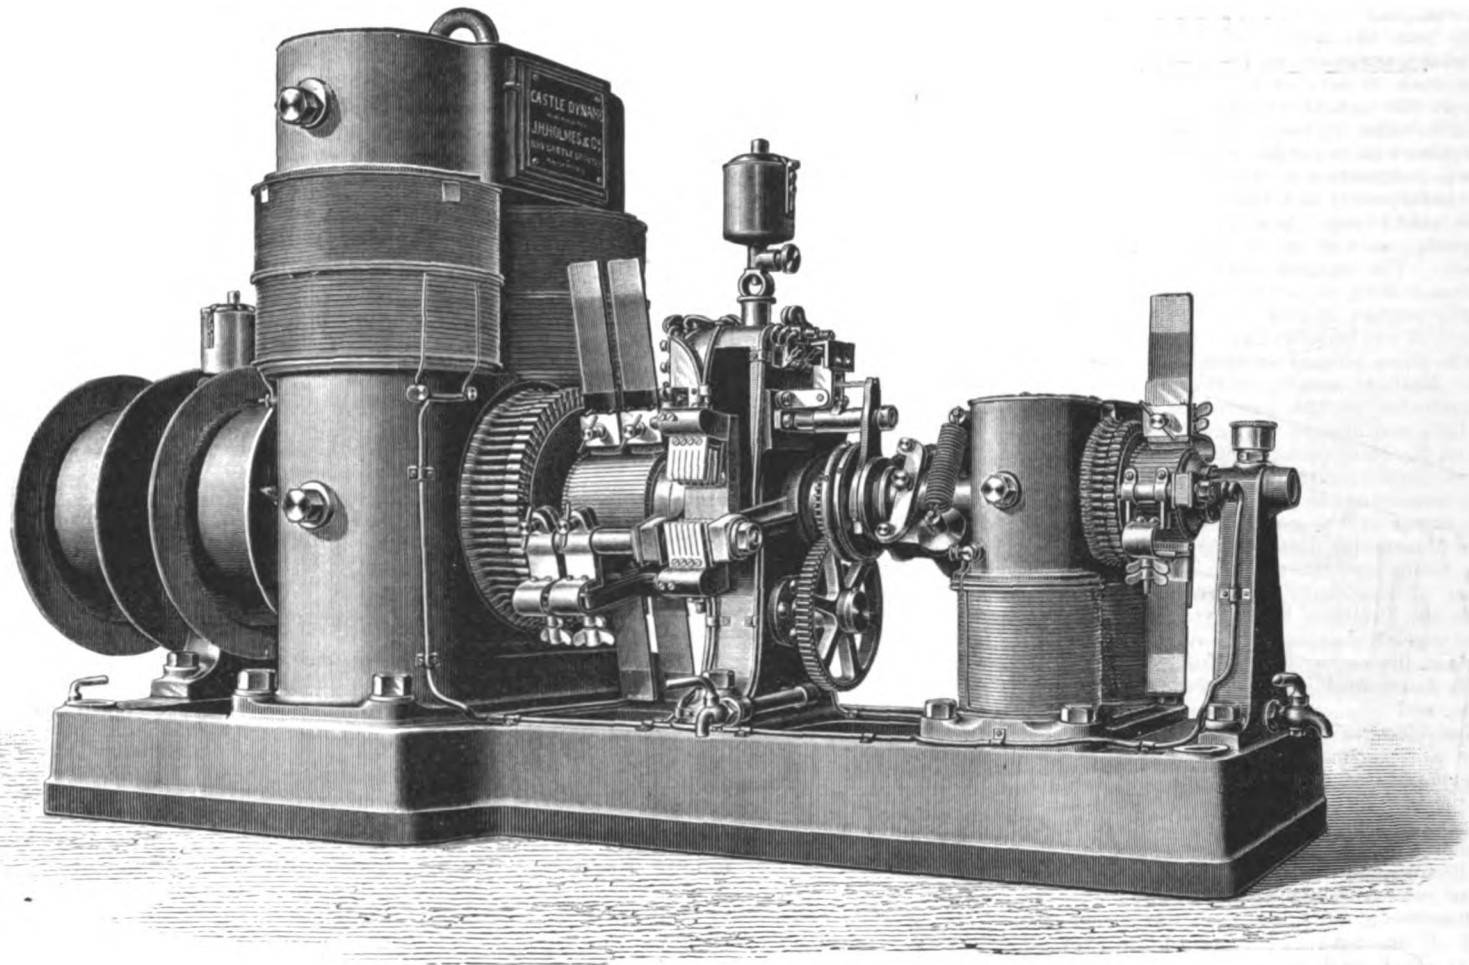
Dr. C. R. A. Wright, F.R.S., read a short paper on "The Training Requisite for Professional Chemists," in which he advocated that the Associateship of the Institute should be conferred on those who satisfied the examiners of their general chemical and scientific knowledge, which could best be obtained in one of the colleges. The full Fellowship should be given to those who, after having qualified for the Associateship, had further undergone a course of professional training in the laboratory of a Fellow, and produced satisfactory evidence that they had there acquired a special training in that branch of the profession they intended to adopt subsequently.

Mr. Lloyd's paper, on "The Best Training for an Analytical Chemist," was next taken, in which the author gave an outline of what he considered an ideal system of education for an analyst, and advocated, after a general education and experience in office and business work, a four years' training in chemistry, each year to be devoted to one particular branch, and the student's knowledge to be tested by an examination at the end of each session.

In the discussion which followed Messrs. Thomson, Norman Tate, Hehner, Allen, and Cassal expressed their several views in favour of some regular and systematic training in the laboratory of a Fellow engaged in an analytical practice before a student should be considered qualified for the Fellowship of the Institute, and Mr. Groves, Dr. Stevenson, Professor Smithells, of Leeds, and Professor Clowes, of Nottingham, supported the view of the Council that the requisite training should be partly acquired in a recognised teaching institution.

MAGNOLIA-LINED BEARING PEDESTALS.

Improved metal pedestal bearings have been recently introduced by Messrs. Allen & Robson, Newcastle-on-Tyne, especially adapted for pit tubs and waggons, which we illustrate herewith. It will be seen they are of ordinary construction, but are lined with magnolia anti-friction metal, which is carefully fitted in. Under the usual system of steel axles running in steel bearings, both the axle and the bearing deteriorate, and thus



frequent renewals are necessitated. It is found that, with these improved bearings, the axles do not appreciably wear away, and while, owing to the anti-frictional properties of the magnolia metal, less lubrication is required, the cost of repairing colliery tubs and waggons is materially decreased, as the iron or steel body of the bearing will last almost indefinitely, without serious accidents occasion a breakage. Any ordinary mechanic can refit the lining of magnolia when it is required because of wearing down, and it is evident that this arrangement should prove productive of real economy.

TRAIN LIGHTING DYNAMO.

CONSTRUCTED BY MESSRS. J. H. HOLMES & CO., ELECTRICAL ENGINEERS, NEWCASTLE-ON-TYNE.

GENERAL VIEW.

HOLMES' TRAIN LIGHTING DYNAMO.

MANY attempts have been made to light trains electrically. The chief difficulty is in the variation of speed of driving the dynamos. Separate engines have been used, but have been found unsatisfactory. We illustrate above a solution of the problem, due to the ingenuity of Mr. J. Holmes, of Newcastle. The inventor explains his dynamo as follows:—

Practically the e.m.f. of an ordinary separately excited dynamo varies directly as the speed, so if the speed be increased, say, from 500 revolutions per minute to 1,000 revolutions per minute, the electromotive force will be doubled. The electromotive force varies directly as the strength of the magnetic field, so that, if the strength of field of a separately excited dynamo be reduced in the same proportion as the speed at which its armature revolves be increased, the electromotive force of the armature will remain practically constant.

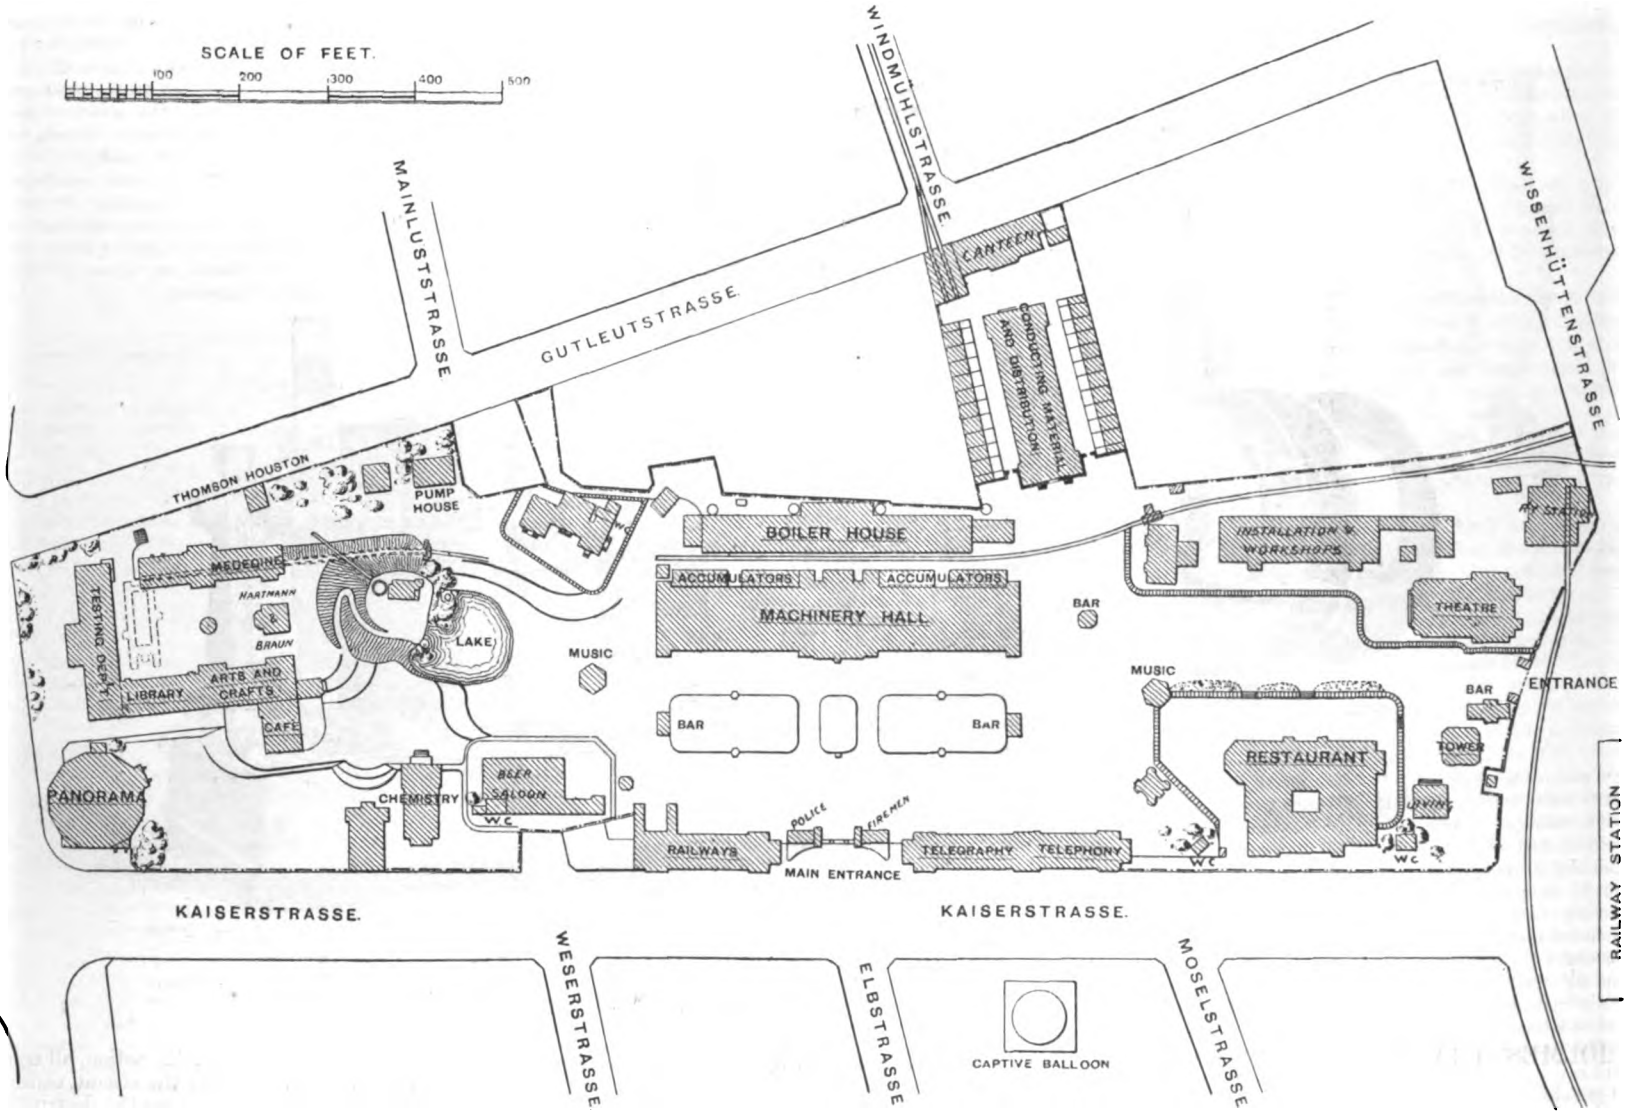
To produce this result two dynamos are arranged having their armatures upon the same shaft, so as to revolve together, but influenced by separate magnetic fields. One is the main generating machine, the other is for regulating the strength of its magnetic field. The magnets of the machines are separately excited from an external source, such as a set of accumulators, and the magnets of the generating armature are provided with two distinct exciting circuits. One circuit is an ordinary high resistance shunt circuit, and the other is of less resistance, and is coupled up to the source of current so as to have the small regulating armature in series with it. The regulating armature is so coupled up that its electromotive force opposes the electromotive force of the regulating armature and external source of supply. The high resistance shunt circuit is so proportioned that, at the highest speed at which it is intended to run the generating armature, it, without the aid of the regulating circuit, will give a magnetic field of an intensity proper for the required e.m.f. in the generating armature. When thus driven the second exciting circuit ought to have no current passing through it, and this is secured by making the e.m.f. of the regulating armature at its highest speed equal and opposite to the external source of e.m.f. produced in the second coil of the generating machine. If, however, the speed falls, the e.m.f. of the regulating armature is reduced in the same proportion, and is no longer equal to the external e.m.f., and a current will flow through the second exciting circuit of the magnets of the generating dynamo, thus increasing the intensity of the magnetic field to make up for reduction of speed, maintaining a practically uniform e.m.f.

The armature is driven by belting from the axle of the guard's van, and a set of accumulators excite the field magnets. A centrifugal governor automatically switches the storage batteries in or out. The brushes which collect the current from the two armatures are made of wire gauze, and are placed radially, the "lead" being automatically altered to suit the direction of rotation. The connections to the armatures are changed at the same time.

This dynamo is used by the Midland Railway Company for their express trains, and has also been applied to French, German, and Russian railways.

THE ROYAL SOCIETY CONVERSAZIONE.

WE referred briefly last week to the conversazione held by the Royal Society in their rooms at Burlington House on the 6th inst.



As usual, a large number of exhibits were on view, all more or less interesting, but we shall confine our attention to the more noteworthy from an engineering point of view. Mr. Wimshurst exhibited his new alternating influence machine, which excites electrical oscillations without giving any continuous current. The machine by which the phenomenon was exhibited was ingeniously constructed in such a manner as to allow, by means of interchanges of various portions, which could be easily and expeditiously effected, of its being transformed into an influence machine of any one of the numerous types which have been devised. An exhibit of considerable interest to electrical engineers was the "Tomlinson Regulator for Electric Light Mains," shown by the manufacturers, Messrs. J. E. H. Gordon & Co. The regulator is intended for use at transformer sub-stations, and is so contrived that, if anything goes wrong with the apparatus, which is automatic in its action, all transformers are immediately thrown into the circuit, causing merely a waste of coal in place of risking the destruction of the station by fire. A very striking illustration of electrical resonance was exhibited by Professor O. Lodge. The arrangement consisted of a pair of similar and independent Leyden jar circuits at a short distance apart. One jar was charged and discharged successively by means of an influence machine included in its circuit, and the other jar, which had the two coatings nearly connected by a slip of tinfoil, so as to provide an easy overflow path, had the length of wire in circuit with it adjusted by means of a slider, until it was seen to overflow at each discharge of the jar in the exciting circuit. Messrs. Richard Frères, of Paris, exhibited a number of delicate specimens of continuous recording apparatus, among which we may mention an aneroid barometer showing variations as small as $\frac{1}{10}$mm., and an ingeniously contrived wattmeter, together with continuously recording voltmeters and ammeters.

Professor Roberts-Austen showed illustrations of a method of photographically recording pyrometric measurements at temperatures between 600° C. and 1,200° C. The measurements were obtained from the indications of a galvanometer in circuit with a platinum-rhodium thermo-couple. The ordinary spot of light was replaced by the image of a fine vertical slit, which, as the current varied, due to changing temperature, travelled along a fine horizontal slit, below which, and perpendicularly to it, a sensitised plate was carried along at a uniform speed by means of clockwork. A number of curves obtained in this way, and showing the rates of cooling of various pure metals and alloys, were shown.

One of the most interesting of the exhibits on view was Professor W. C. Unwin's new length-measuring instrument devised to measure lengths to within $\frac{1}{10000}$ of an inch. A gauge bar, the length of which is accurately known, and not differing greatly from that of the length to be measured, is first placed in the instrument, and the contact pieces which rest against the end of the standard bar are adjusted by means of delicate levels attached to each, and when the adjustment is made the pressure against each end of the bar is a very small but perfectly definite quantity. A micrometer screw, with a play of about 2in., allows of a bar being compared with a standard which does not differ from it by more than that

THE FRANKFORT ELECTRICAL EXHIBITION.

General Plan of Buildings and Grounds.

length. Owing to the complete absence of indefinite strains the instrument can be made to take in objects of considerable diameter, and the measurements can be made for any length for which a gauge bar of accurately known length can be obtained. Professor S. P. Thompson exhibited a focameter for determining the true focal length of any compound system of lenses, such as a microscope objective or a photographic camera lens; and Mr. Shelford Bidwell showed some of the selenium cells which aroused so much interest when exhibited to the Physical Society last year. He also exhibited contrivances, in which they were employed for automatically lighting an incandescent lamp on the advent of darkness, and for giving an audible alarm if a ship's light or railway lamp were accidentally extinguished. A good deal of interest was attracted by some colour photographs of the spectrum exhibited by M. Lippmann. The colours are produced by interference, due to the structure imparted to the film by the stationary waves of incident light during exposure in the camera. It may be noted that similar phenomena were sometimes exhibited by the old daguerreotype films. The explanation of this phenomenon is certainly of considerable interest; the results do not give any indication of progress in the direction of colour photography, as the expression is usually understood. Professor Schuster exhibited several forms of Clark's standard cells. The most noteworthy point about them was the employment of indiarubber valves to allow the hydrogen generated to escape, also preserving the cells from destruction from its gradual accumulation.

THE FRANKFORT EXHIBITION.

The great event of the year to electricians will be the Exhibition at Frankfort-on-the-Main. An exhibition like this must be regarded from two points of view, those of the exhibitor who wishes to further his trade, and of the electrical engineer who wants to study the progress of the industry.

We do not yet know how far our electrical firms will exhibit, but there is little doubt that there will be a fairly representative display of English manufactures. There is, however, a feeling that both the French and Germans prefer to use their own machinery, on Protection principles. There is a very good reason why it is sometimes of little use trying to push English goods in Germany, and that is because the cheapness of German labour enables the Germans to undersell us, especially in their own country; and we have no reason to complain of this. So far we have only heard of one English engine maker and one English dynamo maker exhibiting, and do not know if there are any large French exhibits at all. From the point of view of the electrical engineer who wants to learn, the Exhibition will be exceedingly valuable. Frankfort is a long way off in miles, but it can be reached both quickly and cheaply. Moreover, many people can take it on their way to Switzerland or Italy, for it is on the high road to the districts where people flock in holiday time.

We have recently had a splendid opportunity of comparing French practice with our own at Paris, and a more intimate acquaintance with German design will do no harm.

There will probably be no striking novelties, unless the so-called rotary field motors, which are receiving so much attention just now, can be considered new. There will, however, probably be a good display of large multipolar central station machines and station engines. About 4,000 h.p. in steam engines is already arranged, and there are over 200 h.p. in gas engines.

There is little doubt that, with the talent for organisation for which the Germans are so well known, the Exhibition will be a great success. A glance at the accompanying plan will show that the main engine and machine house is a building close upon 500ft. long, and the rest of the Exhibition is on a correspondingly large scale.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

VIII.

(*Continued from page* 451.)

Manufacturers' Soap.—The best qualities of soap, for manufacturers' use, are made from the nigres of ordinary pale or brown soaps, together with currier's grease or bone fat, and rosin, and the soap fitted without the addition of too much water. Large quantities of manufacturers' soap are, however, made as a curd, from bone grease, kitchen and ship fats, crude recovered fatty acids, and, indeed, almost any kind of fat or grease. This kind of soap, which is sometimes hardened by soaking the bars in strong brine, has a mottled appearance, owing to the dark-coloured impurities present, and it is generally strongly caustic. The presence of a considerable amount of free caustic soda is, however, not only unobjectionable, but is a necessity for the kind of work for which this soap is generally employed.

Palm oil, in conjunction with rosin, is also largely used in the fabrication of this class of soap, but cocoanut, palmnut, and some other oils do not give good results. A certain amount is also made by the so-called "cold process," in a very crude manner, by melting impure tallow or other solid fat at a low temperature in a jacketed pan, which is fitted with a rotary mixer, shown in Fig. 14, and crutching in strong caustic soda solution to effect saponification. The product is then run out into a frame to cool and set. Soap made in this way always contains a large quantity of free caustic soda, and, not infrequently, a considerable proportion of unsaponified tallow or fat.

The olive oil soap manufactured expressly for calico printers, silk dressers, &c., is an entirely different product from the manufacturers' soaps mentioned above, being, as a rule, made from purer materials, and con-

Digitized by Google

taining very little or no free alkali. It usually contains from 60 per cent. to 70 per cent. of fatty anhydrides, and from 6·5 per cent. to 7 per cent. of combined soda.

Soft Soap.—The soda salts of the fatty acids are, as a rule, hard, opaque, and not appreciably affected by the addition of a moderate quantity of water. Potash soaps, on the other hand, especially if made from neutral oils,

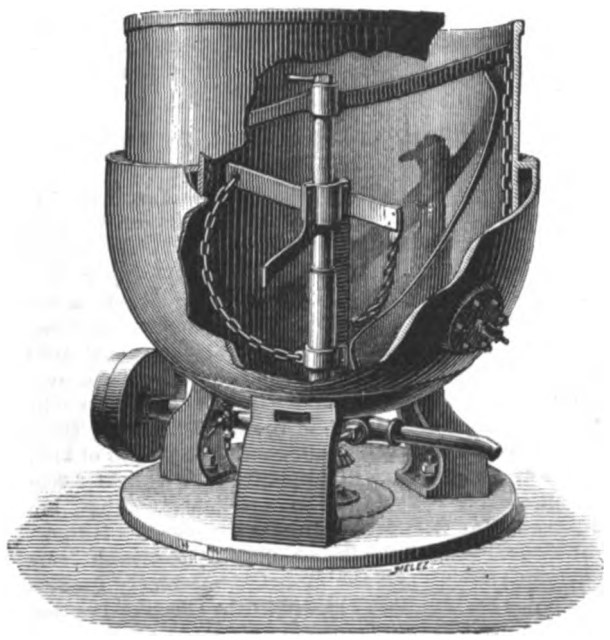

Fig. 14.

are soft, deliquescent, and transparent, and are rendered more soft by the addition of even a small quantity of extra water. Unlike most of the hard soda soaps described, soft soap contains the whole of the extraneous matters of the original oils, as well as the glycerine produced by their saponification. The process of manufacture is very similar to that described for marine or common mottled soap, and is prepared in a similar pan, generally from linseed and cottonseed oils. Hempseed and sometimes crude or green olive oils are also used, while Scotch soft soap is said to be made mainly from cod or whale oil and tallow.

The potash lye for the saponification of these oils is still commonly prepared by acting on a boiling solution of potassium carbonate with hot slacked lime, and allowing the precipitated calcium carbonate (chalk) to settle. The clear liquid is then drawn or siphoned off and diluted to the required specific gravity to form the lye. Other manufacturers prepare their lye from the solid caustic potash obtained in drums similar to those containing the solid caustic soda, and in this case the saponification of the oil is more easily controlled and the result is better, if a certain proportion of carbonate of potash be added to the caustic lye. This fact may account for the preference many soapboilers have for lye prepared from quicklime and pearl ashes, as such almost invariably contains a notable quantity of unacted-upon potassium carbonate.

The device of having a gauge on the lye tank, for the purpose of showing when the requisite quantity of caustic has been run into the pan, is of special value in the boiling of soft soap, as the saponification proceeds rapidly when once commenced, and the lye must therefore be allowed to run in more freely than with most soda soaps, to avoid the risk of the mass becoming thick. The operation is commenced with moderately weak alkali, and finished with strong lye of from 1·15 to 1·20 sp. gr., and the boiling is either begun with open steam and finished by fire, or effected throughout by fire alone. The saponification is materially assisted by vigorous beating with the spade, which is also necessary to prevent the undue swelling up of the boiling and frothy mass.

When finished, the soap boils in a peculiar manner, and has a dark, transparent appearance, the surface being free, or practically so, from "fob"; whilst a small sample, taken from the pan and cooled, has no stringiness, but is "short" and can be "balled" in the hand. The operator also tests the state of the product by its appearance on the knife or trowel, and small samples are allowed to cool on a glass plate. If the result of these observations be satisfactory, the fire is withdrawn from under the pan, and the soap shortly afterwards filled into casks and firkins, in which it is allowed to set.

Soft soap, so made, usually contains about ·5 per cent. of free caustic potash, and from 40 per cent. to 50 per cent. of water. If made from cottonseed or linseed oil, or both, it has a fine golden, sometimes greenish colour, and, on standing for some time, becomes filled with small stellate granules of potassium stearate, a condition which is technically called "figged." This figging is usually, but quite mistakenly, regarded as a sign or proof of good quality, and to produce it a small quantity of tallow is often added to the oils employed. It is also sometimes imitated by the addition of unboiled starch, and other substances, to the made soap.

Hempseed oil soft soap is green in colour and very soft in consistency, as also is soap made from fish oil, the latter retaining an unmistakable and unpleasant fishy smell.

Soft soap is often filled or adulterated with various substances, such as potassium chloride, potassium silicate, dextrin, Irish moss, and starch, some samples containing as much as 10 per cent. of a solution of the latter, which sometimes actually gives a better and brighter appearance to the soap, although, when adulterated in this way, it has little or no tendency to "fig."

(To be continued.)

NOTES ON ALLOYS.

X.

The recent work by Mr. Veley on the action of nitric acid on the metals has shown that foreign impurities in either the acid or the metal determines the solution of the metal, and in his recent paper before the Society of Chemical Industry it was suggested that these experiments might throw some light upon the solvent action of the weak acid upon the lead of vitrol chambers. M. Hochstetter has recently presented to the Société Industrielle du Nord de la France an exhaustive paper on this very question, in which he has shown that the action of sulphuric acid upon lead is protected by the presence of certain impurities such as copper and antimony in the metal. By adding quantities of copper, varying from ·01 to ·04 per cent. of the commercial lead used, he showed that such alloys were not acted upon by acid at 66°, and the same was true when antimony varying from ·1 to ·2 per cent. was added. When the two metals were added to the lead together, much smaller quantities of each were sufficient to protect the lead from dissolution, so that the minimum quantity of foreign metals which must be present to afford protection is a mixture of ·005 per cent. copper and ·05 per cent. of antimony. From some nine trials he further found that this alloy resisted the action of the acid considerably longer than that of lead alloyed with the small quantities of antimony or copper above mentioned.

Mr. Fred. C. Weld has made an interesting addition to Heycock & Neville's work noticed in our last article, which confirms their results in the case of the tin lead alloy, but shows, as is already known in working Raolt's method for determining the molecular weight of organic substances, that the lowering of the melting point of the tin by the addition of the lead is only true when the quantity of lead added is less than in the proportion of 15 atoms of lead to 100 of tin. The following table shows the results obtained:—

Melting Point of Tin (Fine Bar).		Atoms of Lead.		Factor for Lead.		Calculated Melting Point.	Actual Melting Point.
227°	minus	3·28	×	2·22°	=	219·72°	218°–219°
,,	,,	11·24	×	2·22°	=	202·05°	201·5°
,,	,,	15·13	×	2·22°	=	193·41°	194°
,,	,,	17·19	×	2·22°	=	188·84°	193°
,,	,,	19·47	×	2·22°	=	183·78°	188°–190°
,,	,,	38·18	×	2·22°	=	142·24°	180°
,,	,,	57·28	×	2·22°	=	99·84°	180°
,,	,,	85·12	×	2·22°	=	38·03°	209°

It is interesting further to note that the lowest melting point possible is obtained from 38 atoms of added lead, but the author is unable at present to advance any theory to account for these phenomena. He further points out that the effects of this reduction of the melting point are not cumulative, so that at present the law does not hold for the addition of two or more foreign metals. The following table is also given by the author as showing the atomic proportions of some compounds alloys whose melting points he has determined:—

Tin (atoms).	Lead (atoms).	Mercury (atoms).	Zinc (atoms).	Bismuth (atoms).	Melting Points.
100	57·28	12·58	7·04	3·3	145°–150°
100	57·28	8·41	—	2·24	166°–167°
100	57·28	10·58	13·02	4·03	148°
100	57·28	12·82	5·63	2·66	145°

The composition of the alloys for resistance coils is now receiving considerable attention, and here again the influence of small quantities of added metal to the alloy gives very marked differences in their specific resistances and temperature coefficients. Obermaier's nickelin is one of these new alloys which is practically German silver with a somewhat large per centage of nickel. Geitner's rheotan contains about 4 per cent. of iron in place of a corresponding quantity of zinc in the nickelin. Basse and Selve of Altena are also selling for the same purpose an alloy which they term "patent nickel," which practically consists of a mixture of three parts copper and one part nickel, with small fractions of a per cent. of zinc, iron, and manganese. It is difficult at present to connote the physical properties of these alloys with their chemical composition, and until some investigator undertakes the preparation of, say, the series of pure copper-nickel alloys, and then adds thereto varying percentages of the several elements in order, most of this knowledge must remain in its present empirical condition.

The following table is a summary of Feussner and St. Lindeck's determination of the chemical composition and electrical properties of some of these alloys. The manganese alloys examined are those produced at the Isabellen factory at Dillenburg:—

—	German Silver.	Obermaier's Nickelin. A diam. 1·0 mm.	Obermaier's Nickelin. B diam. 0·1 mm.	Rheotan.
Copper	60·10	61·63	54·57	53·38
Zinc	25·37	19·67	20·44	16·89
Tin	—	—	—	—
Nickel	14·03	18·46	24·48	25·31
Iron	0·30	0·24	0·64	4·46
Cobalt	Trace.	0·19	—	—
Manganese	Trace.	0·18	0·27	0·37
	99·86	100·37	100·40	100·31
Spec. resistance	30·0	33·2	44·8	52·5
Temp. co-effic't.	0·00036	0·00030	0·00033	0·00041

—	Patent Nickel. A diam. 0·6 mm.	Patent Nickel. B diam. 1·0 mm.	Manganese Copper.	Nickel Manganese Copper.
Copper	74·41	74·71	70	73
Zinc	0·23	0·52	—	—
Tin	—	Trace.	—	—
Nickel	25·10	25·14	—	3
Iron	0·42	0·70	—	—
Cobalt	Trace.	Trace.	—	—
Manganese	0·18	0·17	30	24
	100·29	100·24	100·00	100·00
Spec. resistance	34·2	32·8	100·6	47·7
Temp. co-effic't.	0·00019	0·00021	0·00004	−0·00003

The negative temperature coefficient of the nickel-manganese-copper alloy is especially noteworthy as well as the high specific resistance of the manganese-copper alloy given in the above table. We hope that further experiments will soon be forthcoming on these interesting alloys, and that they may be found useful in electrical work, for which they seem to be admirably adapted.

SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

At a meeting of this Section, held on the 1st inst., Mr. Ivan Levinstein presided, and spoke at some length respecting reports which had been circulating with regard to the pollution of Manchester air by smoke and fumes from chemical works. He said that a good deal of sensational talk had been indulged in. Every one knew that the air of Manchester was not as pure as at the seaside, but as long as Manchester maintained its position as a great industrial and densely populated centre, and as long as coal was employed as the direct producer of heat, the inhabitants would have to put up with smoke. He wished to point out that the factories and chemical works with their tall chimneys were not such great sinners in respect of smoke as were the thousands of household fires. Chemical and kindred works had lately been denounced by some philanthropists as the chief cause of the pollution of the air, and owners and managers had been put to considerable annoyance and vexatious interference. Such gentlemen forgot that by hampering the works they were inflicting injury on the working classes, whose cause they professed to have at heart. Mr. Levinstein referred to a report on Manchester air recently made by Mr. William Thomson to the Noxious Vapour Abatement Association, which closed with the statement that the greater pollution of the rain water collected in the east of Manchester was no doubt due to chemical works. These reports, he contended, should

Digitized by Google

not be made at random or without the strongest possible evidence of their truth, as they were calculated to do harm and injustice to those who were already labouring under sufficient difficulties and disadvantages. He would suggest the formation of an association for the protection of the chemical and allied industries.

In the discussion which followed, Mr. Thomson justified his report, and Dr. Bailey said that, having spent a good deal of time lately on the air pollution question, he had come to the conclusion that the greater part of the evil was due to domestic fires. Observations which had been taken at Leeds for three years showed that three-fourths of the smoke was due to domestic fires. In an orchid house at Chelsea he had found that, owing to the smoke, no perfect blooms could be grown, while in one in the north of England, near a chemical works, there were perfect plants. Mr. Irvine quoted figures he had obtained from rain collected at Miles Platting—a manufacturing centre—showing that the general condition of the air was as good as in the centre of Manchester.

A discussion adjourned from the last meeting then took place on Mr. W. Thomson's paper, on the "Methods for Determining the Value of Rival Sewage Processes." Dr. Burghardt was present, and met the criticism to which he had been subjected in the paper. Representatives of the International Sewage Process Company were also present and criticised Dr. Burghardt's analyses. As Dr. Burghardt referred to the report recently submitted to the Salford Corporation by the chemists and engineers of the sewage trials, the Chairman said that any one else would be in order in criticising this report. The proceedings were at times of a somewhat lively and personal character, and it was fortunate for the patience of the members that all the defeated sewage process companies were not represented by orators. The discussion is scarcely likely to appear in the Society's Journal, and we shall only refer to two important points on which opinions differed.

With regard to sampling sewage, Dr. Burghardt and Mr. Carter Bell held that a perfectly average sample was obtained by collecting a portion every half-hour for twenty-four hours, and then mixing all together.

Mr. Thomson, however, disapproved of this method, and contended that the fact of more albumenoid ammonia being found in the effluent than in the original sample showed that the analysis of the sewage could not be considered trustworthy. Dr. Burghardt explained this anomaly by saying that the sewage had probably taken up something left at the bottom of the tank, but Mr. Thomson thought that very improbable.

The discussion next turned on "loss on ignition," different opinions being expressed. Figures given in the sewage report showed that in some cases the organic matter in solution was higher in the effluent than in the raw sewage. Mr. Thomson contended that this was due to putting down the loss on ignition as organic matter, whereas he had shown it to contain also combined water, ammonia salts, chlorine from chloride of magnesium, and common salt. Combined water would be found when any of the processes employing hydrated oxide of iron, sulphate of lime, &c., were adopted. Dr. Burghardt, on the other hand, said that he had proved the loss on ignition to be almost all organic matter; combined water did not form more than 1 per cent. of the direct residue. With regard to this organic matter in solution, he attached no importance to it whatever from a sanitary point of view, as it was stable and did not undergo further decomposition. A speaker, representing the "International" process, observed that as Dr. Burghardt had found the loss on ignition to be organic matter containing nitrogen, it was strange that it should not decompose. He himself had found that the loss on ignition represented a good deal besides organic matter.

It was announced that these sewage trials were the largest and most comprehensive that had ever been made, and it was intended that the report should be widely circulated. At present it had been suppressed owing to one or two inaccuracies which had crept in, but it was intended to re-issue it at an early date.

Notes.

PUBLIC WORKS IN THE MOZAMBIQUE DISTRICT.

A WHARF of timber and masonry is to be constructed at Puilimane. This wharf will extend into water having a minimum depth of 6½ft. A concession has been granted for the construction of a light railway, for goods and passenger traffic, between Morguirumba, on the Quaqua River to a place to be chosen on the banks of the Zambesi, near Mopea. The line will have a length of 63 kilometres, and has to be completed within twelve months of the approval of the plans. In the latter part of last year a party of eight Portuguese engineers were sent to the Pungue River to make a survey and report on the advisability of constructing a line of railway from Beira, on the coast, at the mouth of the Pungue River, to Manica or Massi-Kesse, on the Revue branch of the Busi River. The proposed route has been found to run through most difficult country. At Beira the line will have to be built on bridges for many miles, as all the country round the mouth of the Pungue River is very swampy. On the other side of the swampy district the country becomes rocky and full of rivers and small streams, yet, notwithstanding all these difficulties, the proposed route has been favourably reported on.

THE CHIGNECTO SHIP RAILWAY.

MORE or less work was carried on during the latter part of the winter at the Tidnish end of this project. Blasting was done in the bottom of the basin under the ice. No less than 1,330 holes were cut through the ice, which formed a platform and admitted of the work being prosecuted much more advantageously than it could be in summer, though its rise and fall with the tide added to the difficulty. The rock, states the *Railroad Gazette*, lay 10ft. to 15ft. under water. Between two and three tons of dynamite was used.

TRAFFIC OF THE SUEZ AND SAULT STE. MARIE CANALS.

THE traffic of the Suez Canal for 1890 was 3,389 vessels registering 6,890,014 net tons, as against 3,425 vessels and 6,783,187 tons for 1889. The traffic of the Sault Ste. Marie Canal, at the foot of Lake Superior, during the 234 days navigation was open in 1889, was 9,576 vessels and 7,221,935 net tons, and in 1890 it was 10,557 vessels and 8,454,435 net tons—that is to say, in 1889 the lock at the "Soo" passed 11 per cent. more tonnage than the Suez Canal, and, in the 228 days that the canal was open last year, 22·8 per cent. more tonnage passed through it than passed through the Suez Canal.

RICE CLEANING IN RUSSIA.

A MILL has been established at Baku by the enterprise of Mr. Hume and Mr. Lister, both Englishmen, where the uncleaned rice supplied from Persia undergoes a process of cleaning and polishing during which the breakage is almost *nil*, owing to special improvements in the system of the works. The yearly output of cleaned rice is about 3,000 tons. This is one of the new industries that have recently sprung up in Russia, and may be said to be a most promising undertaking, considering the great quantities of uncleaned rice procurable in Persia and the proximity of rice-growing districts of Baku and Elizavetopol, which, if properly irrigated, would be capable of yielding over and above the home requirements a considerable surplus for export purposes.

STEAMERS WANTED IN CHINA.

As almost the whole carrying trade at Ichang is done during the winter months, when the water is often less than 5ft. deep, some powerful stern-wheel steamers are required, with a draught of not more than 4ft., but capable of carrying 1,000 packages of merchandise, and with good passenger accommodation, as the passenger traffic is steadily increasing. A recent official report states that the steamers should be provided with a small steam launch, in order that soundings may be taken in places where the water is low, and to mark out a safe passage. The steamers suggested should be able to make the trip from Hankow in four days, in place of the eight to twelve days that are now often taken.

PUBLIC WORKS AT BORDEAUX IN 1890.

THE construction of the new vertical stone quays on the left bank of the river in the harbour of Bordeaux has proceeded somewhat slowly, and will hardly be finished within the appointed three years. The many difficulties attending the discharging and loading the largest class of vessels at Bordeaux, and the great inconvenience and discomfort to which passengers using the large steamers running between Bordeaux and transatlantic countries are frequently subjected now on landing or embarking in the River Gironde, have led one of the most important French steamship companies to apply to the Government for permission to construct extensive landing stages at Pauillac, the outport of Bordeaux, and situated about twenty-five miles from the latter town. The Bordeaux Chamber of Commerce, which for some time opposed this project, on the alleged ground of its being prejudicial to the interests of Bordeaux has now, it appears, itself asked for authority to carry out the work, and establish landing stages at Pauillac for general use. A large naval medical college erected in the town by the municipal authorities for the French Government was inaugurated at the end of last year, the other college of this kind, situated at Lyons, having become too small for existing demands. A work, which is of considerable importance for vessels arriving in the River Gironde with petroleum from America, has lately been completed at Laroque, a few miles below Bordeaux, and consists of a large iron reservoir capable of holding 5,000 cubic metres of petroleum.

THE ELECTRICAL UTILISATION OF WATER-POWER

AN important work, according to the *New York Electrical Engineer*, has been undertaken by the South-Western Electric Light and Water Power Company for the utilisation of water-power situated near the city of Joplin, Mo., U.S.A., for electrical purposes. The scheme includes a fine natural water-power about 5½ miles from Joplin, and when the present installation is completed will cause about 2,000 effective horse-power to be available. A large concrete dam has been constructed, and the turbines have been built by Messrs. Jas. Leffel & Co., of Springfield, Ohio. These turbines have 66in. wheels and work under a head of 21ft. The electrical equipment consists of one 1,500-light 2,000-volt alternating dynamo and two 50-light 2,000 c.p. arc machines. The electric light from these machines is transmitted to the city of Joplin, which is 5½ to 6 miles away from the station. All the electrical machinery for this installation has been been supplied by the Thomson-Houston Company.

INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE Engineering Section of the International Congress of Hygiene and Demography have adopted the following as their programme, and have already been fortunate enough to secure promises of a good supply of papers:—I.—Sewerage and Sewage Disposal—(A) Water-carriage System; (B) Other Systems. II.—Water Supply. III.—Pollution of Rivers. IV.—Town Refuse. Such subjects as street paving, street subways, heating and ventilation, and house drainage, subjects which by many will be thought to belong to the Engineering Section, are absent from its programme. This is due to the fact that the Architectural Section have undertaken to deal with those subjects. The Committee of the Section are of opinion that the subjects they have undertaken should be dealt with as thoroughly as time will permit, and if sufficient funds should be placed at the disposal of the Central Committee the papers and discussions will be printed *in extenso*. The acting honorary secretary, Mr. R. E. Middleton, of 35, Parliament Street, S.W., will be glad to receive any information which may be considered to be of service to the Section, and trusts that the objects of the Congress, which are to diffuse knowledge of hygiene, may be widely published.

BOILERS REGISTRATION BILL.

THE Engineering Trade Section of the London Chamber of Commerce, at their meeting held on the 22nd ult., after considering the provisions of this Bill, adopted the appended memorandum embodying the conditions which they consider should be observed in any legislation affecting the registration of boilers and designed to reduce the number of explosions arising from various causes. The Committee were of opinion that the Bill, if amended in accordance with their suggestions, would better effect the object which its promoters have in view:—1. That every boiler owner shall register his boiler or boilers at the Board of Trade, with particulars (as per the schedule to the Bill) of every boiler owned by him, together with full data and the name of his engineer or other person directly responsible for the condition and management of the boiler or boilers. 2. That the Board of Trade shall keep a register of all boilers and their owners, and of the managers responsible for the same, and shall take proceedings against boiler owners who neglect to have them registered in due course. 3. That the Board of Trade may cause an examination to be made in the case of all explosions, and shall make such an examination in every case where explosion causes damage externally to the boiler or injury to life or limb, or both, and the Board of Trade shall prosecute the party or parties whom they consider to blame. 4. That the boiler owner shall pay a small fee to the Board of Trade to meet the expenses of registration and prosecution.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

27th April, 1891.

7205. The Gaseous and Liquid Fuel Supply Company, Ld., & Thwaite — Injecting and spraying gaseous and liquid fluids.
7208. Elcoate, T. — Valve gearing and valves for steam engines.
7212. Alley & MacLellan — Steam steering machinery.
7218. Williams, H. — Gas motor and similar engines.
7218. Bradley & Black — Machinery for drilling the holes in circles, fallers, and the like.
7219. Riley, R. — Foundry spindle for moulding purposes.
7220. Wilkinson & Wilkinson — Signalling apparatus.
7224. Washington, S. — Weighing machines.
7232. Whitehead, J. — Apparatus for supplying fuel to steam boiler furnaces.
7233. Brampton, C. H. — The manufacture of driving chains.
7245. Haddan, R. — Rotary air engines (*Müller*).
7250. Hoare, W. — Circular saws.
7256. Alder, V. — Priming caps or exploders.
7257. Johnson, J. Y. — Apparatus for producing an artificial draught in furnace flues and the like (*La Société Geneste, Herscher et Cie.*).
7263. Collier, J. — Motive power apparatus.
7267. Murrie, J. — Apparatus for feeding water into steam boilers or evaporators and alarms connected therewith.
7269. Ephraim, A. — Spreading disc for petroleum and gas burners.
7270. Klein, T. — Brake apparatus for railway waggons, &c.
7275. Boult, A. J. — Pitch or driving chains (*Moxon*).

28th April, 1891.

7293. Marks, R. G. — Locking railway signals.
7295. Suydam, J. — Automatic pipe-couplers for railway cars.
7297. Sibley, D. E. — Machine for scouring grain. (27th October, 1890.)
7298. Gerdom & Reynolds — Breechloading ordnance.
7299. De Baere, P. — Rock drills.
7301. Tozer, Stanton, & Stanton — Apparatus for transferring mails to and from trains in motion.
7302. Jarkovski, I. O. — Steam boilers.
7303. Maxon, Boyer, & Staniland — Lifting jacks.
7307. Newton, H. E. — Direct-acting engines (*Worthington*).
7309. Bishop, A. — Means for presenting metal work to the action of emery wheels.
7313. Pinkney, C. W. — Gas engines.
7316. Buckman, S. Y. — Apparatus for joining, coating, and treating sheet metal plates.
7317. Lake, H. H. — Axle boxes for railway vehicles (*Godley*).
7325. Fell, J. C. — Locks of firearms and safety devices combined therewith (*Whitney*).
7329. Wicks, F. — Type composing machines.
7338. Dixon, F. N. — Travelling cranes.
7344. Jensen, C. A. — Mechanical movements (*Edleblute & Mueller*).
7352. Conolly, H. — Air-tight manhole covers.

29th April, 1891.

7354. Brett, E. S. — Steam stamps.
7365. Nance, W. — Apparatus for dressing or separating ores of tin or other metals or minerals.
7366. Wormald & Washington — Shedding motion of looms.
7375. Sharp, T. — Cogging mills.
7384. Marsland, Coldwell, & Coldwell — Heating water by exhaust steam.
7385. Miles, H. A. — Circular saw table for use in lathes.
7386. Roberts, L. — Brake mechanism of vehicles mounted on bogie wheels.
7387. Speight, Jarvis, & Sellers — Rollers for carding machines.
7390. Schofield, J. W. — Method of fixing wheels on the axles of railway, tramway, or other rolling stock.
7395. Adams, J. A. P. — Lathes.
7401. Hartmann & Thomson — Leather paring machines.
7407. Hills, G. — Mechanical time and percussion fuses for projectiles.
7413. Seward, T. — Safety brake or locking device for lifts.
7415. Kummer, Fischinger, & Leck — Centrifugal governors for engines.
7418. Bousfield, J. E. — Mountings for quick-firing guns (*Ternstrom & Widell*).
7425. Horn, W. W. — Appliance for moving railroad switches (*Washington & Roberts*).
7426. Horn, W. W. — Railway track (*Kendall, Hunt, & Fay*).
7432. Breething, E. — Machinery for moulding bricks.
7436. Wills, J. — Construction of screw propelled boats.

30th April, 1891.

7444. Ulrich, F. — Drilling machines.
7455. Hall, H. R. — Engine governors.
7472. Swindells & Peel — Apparatus for transferring mail bags or similar articles to or from trains in motion.
7477. Hundleby, R. — Metallic sleepers, chairs, and rail joints.
7482. Comings, W. R. — Mechanism for applying, exerting, and controlling band friction.
7491. McGrath, Jones, & Carter — Combined supply, cut-off, expansion, and exhaust valves with automatic variable gear for steam engines.
7499. Bousfield, J. E. — Breech mechanism for quick-firing guns (*Bergman*).
7500. Marc, E. C. — Ramie machinery.
7510. Marshall & FitzGerald — Air propelling or ventilating.
7511. Decock, E. — Machinery for dyeing textile materials in hanks.
7512. Lane, F. R. — The valve gear of engines.
7517. Farrer, F. T. — Cocks or valves.
7519. Barlow, W. A. — Hydraulic motor (*Guignet & Bloemendaal*).
7520. Wright, P. — Engine slide valves.
7521. Preston & Nelson — Compressed air or gas motor.
7525. Bertram, D. N. — Paper-making machines.

1st May, 1891.

7530. Miller, A. — Heating feed-water of steam boilers.
7538. Rylands & Emmet — Machinery for making bottles.
7545. Tattersall, W. — Apparatus for humidifying air.
7551. Murrell, S. — Flues for marine boilers.
7556. Willoughby, Ackroyd, & Ackroyd — Apparatus for utilising the waste heat of marine boilers.
7557. Pirnie, G. — Method of or means for propelling vessels.
7559. Scott & Fenley — Steam engines.
7561. Giblis, H. — Charging retorts.
7566. Gray, A. — Vaporisers for petroleum engines.
7579. Edwards, E. — Apparatus for ejecting or withdrawing vapours and gases from pipes (*Rohrmann*).
7580. Bell & Welsby — Lifts, elevators, and similar machinery.
7581. Roberts, H. P. — Vaporisers.
7587. Robinson, A. S. F. — Thrashing machines, traction engines, and other road locomotives.
7588. Thomas, H. M. — Governors for motive power engines (*Sainsbury*).

2nd May, 1891.

7600. Noble, A. — Apparatus for working guns.
7602. Langfield & Sharples — The consumption of smoke and apparatus therefor.
7611. Fraser, P. — Screw-tapping mechanism.
7612. Semmler, A. — Straight bar knitting machines.
7625. Tropenas, A. — The manufacture of steel, steel castings, or ingot iron, and apparatus employed therein.
7626. Barker, R. L. — Spiral springs for pistons and air pump buckets.
7632. Mowat, J. G. — Securing the foundation fabric of card clothing to the bars of flat carding engines.
7643. Anderson, R. — The bending of metal tubes.
7644. Lane & Ashford — Apparatus used in the soldering of the seams or joints of metallic tubes.

ELECTRICITY.

27th April, 1891.

7204. Kingsland, W. — Electric alarms.
7210. Jarvis, G. A. — Incandescent lamps.
7225. Nussbaum, G. A. — Telephonic transmitters.

28th April, 1891.

7278. Percival, G. — Electric switches and circuit closing and opening devices.
7283. Bennett, A. R. — System of telegraphy and telephony.
7331. Abel, C. D. — Telephones (*Société Générale des Téléphones—Reseaux Téléphoniques et Constructions Electriques*).
7333. Thompson, W. P. — Dynamo-electric machines (*Tischendorfer*).

29th April, 1891.

7353. Bayly, J. P. — Electric railway systems (*Weems*).
7355. Atkins & Atkins — Electrical fittings.
7372. Bolton & Mountain — Apparatus for actuating hammering, caulking, rock-boring, or like percussive machinery by electricity.
7427. Horn, W. W. — Electric time locks (*Flowers, Jones, & Price*).
7430. Heaviside, Jackson, & Richardson — Equalising motion pulley for alternating current dynamos.
7433. Salomons, Sir D. L. — A leakage detector for electric lighting conductors.

30th April, 1891.

7479. Keller, E. E. — Underground conduits for electric railways.
7493. Sperry, E. A. — Mounting dynamos and motors upon rotating axles.
7529. Shann, G. — Dynamo-electric machine.

1st May, 1891.

7531. Cuthbert, A. — An insulation cutter.

2nd May, 1891.

7603. Yule & Stewart — Electric signalling apparatus for passenger trains.
7614. Walker, T. P. — Regulating the brilliancy of incandescent lights.
7661. Thomson & Foyster — Putting transformers in or out of circuit.

CHEMISTRY.

27th April, 1891.

7258. Johnson, J. Y. — Production of dyes belonging to the rhodamine series (*Badische Anilin & Soda Fabrik*).

28th April, 1891.

7282. Claus, W. H. — Process for the manufacture of pyrogallic acid.

29th April, 1891.

7362. Kellner, C. — Apparatus for recovering sulphurous acid used in the manufacture of paper pulp from wood.
7434. Nodon, A. — The electrolysis of chlorides and the utilisation of the liberated chlorine for the manufacture of chlorates and hypochlorites.
7437. Fleischer, E. — Manufacture of alkali aluminates.

30th April, 1891.

7464. Hop, A. — Carburating or carbonising apparatus.

2nd May, 1891.

7654. Brindley, G. F. — The production of solid compounds of sulphuric acid and acid sulphate of sodium or potassium.

MISCELLANEOUS.

27th April, 1891.

7223. Charlopin, C. — A solution or fluid for motive power or heating purposes.
7228. Nagel, E. — Leather belting with steel facing.

28th April, 1891.

7284. Cruikshank, G. M. — Gas burners (*Bergeon*).

29th April, 1891.

7396. Prosser, H. W. — Spanners.
7400. Rizzoni, P. — Axle journals.

30th April, 1891.

7445. Shepard, J. W. — Instruments for obtaining angles, levels, perpendiculars, and gradients.
7450. Cuttler, Cuttler, & Cook — Life guards for tramway and other engines.
7487. Haddan, R. — Magnesium flash lights (*Engel*).
7513. Crang & Harris — Hooks for disengaging boats.

1st May, 1891.

7558. Loewenthal, L. — Production of gas.
7583. Bourân, J. D. — Coal gas retorts.
7590. Brewster, F. W. — Connecting and disconnecting ships' boats.

2nd May, 1891.

7593. Jones, T. W. — Railway chairs.
7607. Walker, J. — Rod packing.
7619. Falconer, R. — Miners' lamps.
7624. Armour, A. — Packing for water-gauge glass tubes (*Armour*).
7628. Walton & Walton — Washer.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Boiler Furnaces.—*E. Broadhead, W. Beesley, & D. Evans, Barrow.*—The generation of heat in steam boiler furnaces constructed according to this invention is effected by assisting the combustion of inflammable gas introduced into a furnace, by directing streams of air upon the burning gas. Inflammable gas (preferably "producer gas") is introduced into the furnace through a pipe or tube, and two or more currents of air heated in an air pipe and led through the flue in a zigzag fashion are caused to meet the incoming gas at a point immediately above the grate, the branched and perforated ends of the air pipe and the end of the gas pipe over the fire being protected by refractory material. The air is forced through the zigzag tube by a steam blower. A furnace grate of ordinary construction is provided, but of somewhat less length than usual, and a bright coal or coke fire is kept up, the flame of which ignites the incoming gas, and warms the air admitted through the bars into a combustion chamber formed by a brick lining in the flue, over the grate, the heat of the lining serving to continue the ignition of the gas while fresh charges of fuel are burning up. Claims: Causing heated air to be directed upon inflammable gas as it enters the furnace over the fire; the conducting pipe for air, arranged within the flue, and the steam jet.—No. 8510. June 2nd, 1890. 8*d*.

Die Stocks and Dies.—*W. P. Thompson, Liverpool.* (*J. S. Fletcher & J. S. Emmert, Chicago, U.S.A.*)—This arrangement is designed for accurately varying and determining the gauge of the die with reference to the bolt or article to be operated upon, to provide a separable die stock and die with a guide adapted to be held therein by the means employed for holding the die; to adjust the

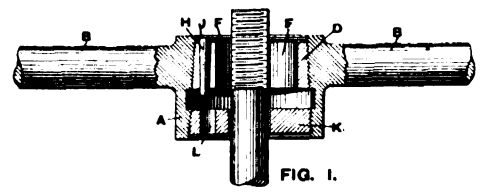

FIG. 1.

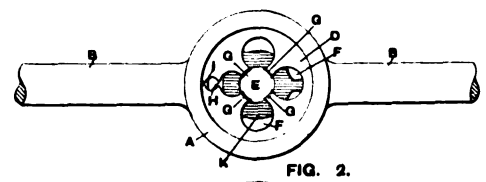

FIG. 2.

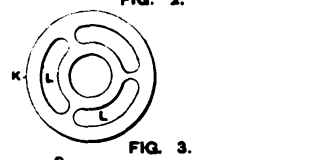

FIG. 3.

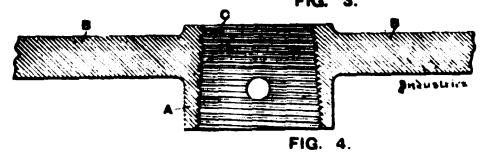

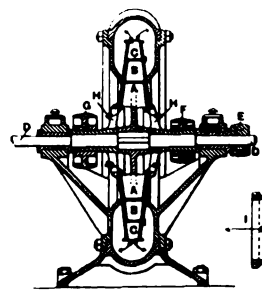

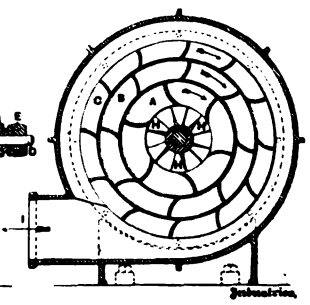

FIG. 4.

die with nicety and hold it firmly; and it is claimed that the arrangement here described constitutes a simple and cheap tool. Fig. 1 is a central section through a die stock and die showing a bolt in the die, Fig. 2 is a plan of the same without the bolt, Fig. 3 is a plan of the guide, and Fig. 4 shows a stock having its bore threaded from end to end. The die stock is formed with a hub A having one or more arms or handles B; the hub is provided with a tapered bore C preferably threaded from end to end as in Fig. 4, or, if desired, the bore, as in Fig. 1, need not be threaded throughout its whole length. The cutter D is tapered and externally threaded to screw into the hub, taking up a position within its smaller end. The central opening E in the die is preferably formed with recesses F passing through the die, which recesses receive the cuttings, the wall portions G of the die between the recesses being provided with cutters for threading the bolt. The die is split through at H, the split permitting the die to expand and contract in conformity with the diameter of the tapered bore; thus the location of the die within the bore can be changed to determine or vary its gauge. The walls of the split or gap H are provided with notches or recesses I for the reception of a pin J to jam the die within the bore. A guide K is located within the other end of the tapered bore and is provided with a central opening L to fit the bolt or rod to be threaded, which guide is provided with several slots as shown, which serve to receive a wrench for turning the guide or a tool to act upon the pin J, and also serve to pass the cuttings. The inventors desire to cover any equivalent arrangement in which, broadly considered, a hub or holder having a tapered bore and a die adapted to wedge within the said bore are provided. Claims: The combination referred to in the last preceding sentence, and the combination fully described above.—No. 3327. February 24th, 1891. 8*d*.

Steel Manufacture.—*W. Hodge, Yatton, Somerset.*—The method described in this specification is similar to the cementation process, but differs therefrom by the employment of a material for producing carbonisation, which, while effecting the desired result in a single process, does not blister the surface nor affect the grain or the internal structure of the iron as does the wood charcoal employed in the cementation process. The substance employed is spent tan, which, having been partially or wholly charred, is put into the box or crucible with the wrought-iron goods, as is customary. The boxes or crucibles are well luted, and exposed to a moderate furnace heat for such time as is necessary for the amount of conversion required, and the furnace is afterwards allowed to cool down. Claims: The steelification of wrought iron in a manufactured or partially manufactured state by the application of carbonised spent tan as described.—No. 7253. May 9th, 1890. 6*d*.

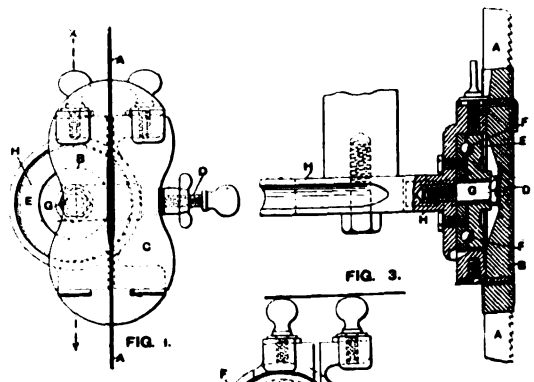
Centrifugal Fans.—*Carl Wenner, Zurich.*—A compound centrifugal fan for delivering a high-pressure blast is illustrated herewith, in cross section in Fig. 1, and in longitudinal section in Fig. 2. It consists of three fans A B and C, each provided with an annular series of vanes and being mounted so that each

FIG. 1.

FIG. 2.

series revolves independently of the other and in the same direction about a common axis, but the different series rotate with different angular velocities which are so related that their circumferential or peripheral speeds are about equal. With reference to Fig. 1 it will be seen that the series A is fixed on the central shaft D, and is driven by the pulley E which is keyed thereto, the series B being formed upon the right hand disc, seen in section, secured to the long boss carrying a driving pulley F and turning freely upon the right hand end of the shaft D, and the series C forming part of the left hand disc turns freely with the left hand boss and its driving pulley G upon the opposite end of the shaft. Portions of the arms carrying the series B and C are formed as screw surfaces at H, to allow the air to enter the fans freely at the centre. Air drawn in and brought to a certain pressure by the first fan would be delivered to the second fan (see also Fig. 2), which would impart to it additional pressure, thus the air would enter the third fan C at a still higher pressure, which by the action of the last fan is still further augmented, so that the air can be brought to a pressure approximately double or triple (according to the number of fans) of that pressure which would correspond to the circumferential speed of only one of the fans. On leaving the last fan C the air passes into the annular casing and leaves it by the outlet I. Claims: A compound fan composed of two or more single fans running at different speeds substantially as described; forming the spokes or arms carrying the series B and C as screw blades, for the reason stated above.—No. 17607. November 3rd, 1890. 8*d*.

Band Saw Guides.—*J. & J. Plumridge, High Wycombe, Bucks, & S. Jackson, Chinnor, Oxford.*—The arrangements illustrated are designed to provide a support for the back of the saw and for the sides thereof, in such a manner that the alignment of the saw will be preserved, the thrust of the back of the saw being taken by the face (and not by the periphery) of a disc arranged to turn freely on its axis, and supported by anti-friction balls, or by backing-rollers, in order that the pressure of the saw on the disc may not cause it to cant and the position of the axis thereof to be sensibly displaced, as has been the case where an unsupported disc has been employed, and also where the saw has been given a bearing upon the periphery of a roller. To keep the saw in adjustment laterally a pair of wooden guides or rubbing faces are arranged, one on each side of the blade, one block being clamped in position and the other being adjustable to admit the



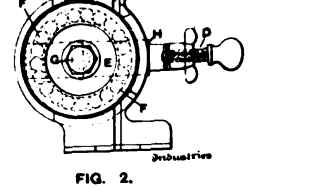


FIG. 1.

FIG. 3.

FIG. 2.

passage of saws of different thickness. A front view of one modification is given in Fig. 1 herewith, Fig. 2 being a like view with the saw and the wooden guide blocks removed, and Fig. 3 being a section on the line X Y of Fig. 1. In these views A is the saw, B the fixed wooden guide, C the moveable one with its adjusting screw D, E is the disc taking the thrust of the rear of the saw, F the supporting rollers, and G the pin on which the disc rotates, the whole arrangement being carried by a bracket or arm H adjustable upon the machine to suit variations in the work. Claims: The combination of the revolving disc with an anti-frictional supporting device.—No. 5129. April 2nd, 1890. 8*d*.

Digitized by Google

MARINE ENGINE GOVERNORS.—*J. D. Churchill, London.*—This invention relates to the governing of compound engines and consists of an arrangement wherein the governor, which may be of any suitable kind, operates the throttle valve and also operates what are termed compound attachment valves, these latter affecting the low-pressure cylinder. Two compound attachment valves are employed, one placed near each end of the low-pressure cylinder, to avoid loss by clearance. Stop valves in connection

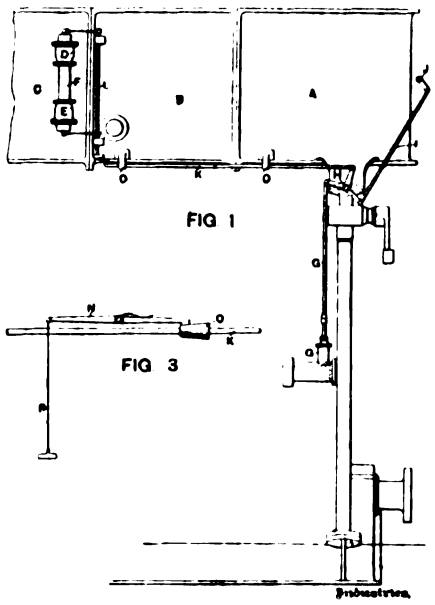

FIG 1

FIG 3

with the attachment valves are dispensed with. Fig. 1 illustrates in side elevation a view of part of a triple-expansion engine to which the apparatus above referred to is attached, A, B, and C being the high, intermediate, and low-pressure cylinders respectively, D and E being the two compound attachment valves attached to a connecting pipe F, so that when both valves are opened they place the upper and lower ends of the low-pressure cylinder in communication and the low-pressure piston in equilibrium. G is the governor, preferably of the inventor's own construction, operating the three-armed lever H, a rod I from one of the arms controlling the throttle valve at J, another arm operating the rod K, which, by the vertical shaft L, controls the compound attachment valves. From Fig. 2 it may be seen that one end of the rod K is provided with a pin working in a specially formed slot, in order that the governor, which actuates the rod K simultaneously with the actuation of the rod I by which the throttle-valve is closed, may not open the compound attachment valves until the throttle-valve has been closed to a predetermined extent; consequently steam will not be lost in the low-pressure cylinder unless the speed of the engine rises excessively; moreover, the speed of the engine will not be too suddenly checked. When the governor acts in the opposite direction, the valves D and E, if these have been previously opened, will be closed by the action of the pin of the rod K upon the shoulder M and the upper portion of the slot shown in Fig. 2, and thus the low-pressure cylinder resumes work simultaneously with the high-pressure cylinder, and the engine resumes work smoothly. Other forms of apparatus for effecting similar results are described.

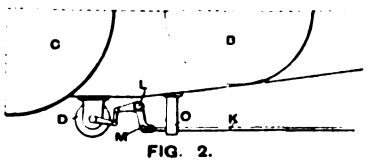

FIG. 2.

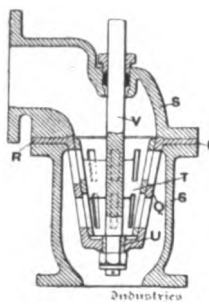

FIG. 4.

Fig. 3 shows a detent N which turns upon a pivot carried by the framing of the engine; this detent engages with a collar O carried by the rod K, and is stated to lock the valves D and E in their closed position in the event of the engine racing excessively or breaking down. The collar O may be released by pulling the wire P. Fig. 4 shows one of the compound attachment valves in vertical section, in which Q is a tapered slotted valve seat formed with a flange R, by which it is secured between the upper and lower parts of the valve case S. A correspondingly tapered slotted valve T is adjustable for wear by a screw nut U, journaled on a reduced part of the valve spindle V, and able to work through a screw-threaded hole in the lower end of the valve seat. In another modification a collar on the valve spindle keeps the spindle in place by bearing in a recess in the stuffing-box, which itself may be adjusted by screwing it into or out from the valve casing, so keeping the valve down to its seating. Claims: The compound attachment valves (or valve) on the low-pressure cylinder operated by slotted connection from the governor as described; also the provision of two compound attachment valves located as described and operated by the governor, the device illustrated in Fig. 3, and a method (not shown above) of controlling the governing valves by an arrangement of levers and flexible connections; and the two modifications of the compound attachment valve.—No. 6590. April 29th, 1890. 11*d.*

SMOKE PREVENTION.—*S. K. Barnes, London.*—This specification describes an apparatus intended for application to boiler or other furnaces for the prevention of smoke where slack or small bituminous coal is used as fuel, and the appliance consists of an induction apparatus whereby heated air is injected into the furnace above the fire by means of a jet of dry steam. To the inner side of the furnace front is applied a pipe, arched to lie close up against the crown of the flue; the two ends of this pipe are brought through the dead plate and turned out below it, as air supply inlets. At the top of the arched pipe are introduced one or more steam pipes, taken from any convenient part of the boiler into an injector jet piece placed horizontally under the furnace crown and forcing a combined jet of air and steam over the fire towards the bridge. Owing to the air inlet pipe being placed inside the furnace front the air will have become considerably heated by passing through the hot pipe before mixing with the jet of steam, and the steam will thus be well dried before admission to the furnace. The action of this jet also induces a better flow of air through the fire-bars in addition to the natural draught, which will consequently tend to raise the rate of combustion per square foot of fire grate, and so keep up a better evaporation. Claims: The combination with induction air tubes placed within the furnace front of an injection nozzle or nozzles fed with dry steam and controlled by a regulating valve; the specific arrangements described.—No. 8418. May 30th, 1890. 6*d.*

PIPE CUTTING AND SCREWING.—*A. Göbel, Ems, Germany.*—The piece of apparatus shown in longitudinal vertical section in Fig. 2, and in end elevation in Fig. 1, is one in which the pipe to be cut or screwed is introduced into the central or axial opening from the right hand, automatically gripped and centred by a clamp at that end, whilst a cutter is rotated, or rotated and advanced, about the opposite end. A support A is provided with a horizontal hollow shaft, about which the headstock and hollow sleeve B are rotated by a worm C operated by the handle D and gearing into the worm-wheel E, which is integral with the headstock and sleeve. The headstock carries a cutter-head F, of known construction, which rotates with it, and which may receive motion in the direction of its axis, but is prevented from

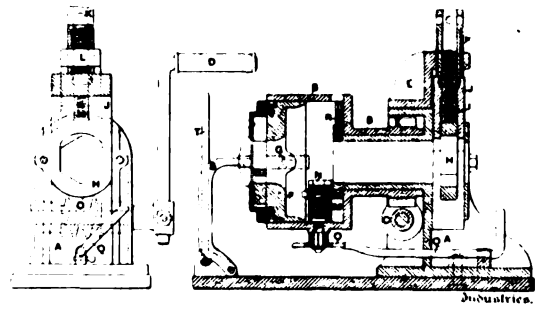

FIG. 1. FIG. 2.

receiving independent rotation by two stops G, which work in slots provided for that purpose in the headstock. The automatic centreing clamp is at the opposite end of the machine, and is thus arranged:—A ring H carrying a screwed spindle I is adjustable vertically within a jaw J, the lower edges of which are cut out at an angle of 120 degrees, as shown, the lower internal edge of the ring H being similarly cut out, so that a cylinder or pipe inserted in the opening between the two comes into contact with four points on the four inclined faces, both ring and jaw sliding in ribs on the support A to prevent lateral displacement. A hollow stud K passes through a lug L on the support A, and is threaded externally for the purpose of raising and lowering the jaw J, to which its lower end is attached; it is also threaded internally with another screw of double the pitch of the external screw for the purpose of receiving the screwed spindle I of the ring H; thus the motion of the jaw J and ring H relatively to each other is such that any circles inscribed in the space between the jaws will have a common centre concentric with the axis of the sleeve B and head F. Screw-cutting discs are fitted in the headstock and operate in the usual and well-known manner. For cutting off lengths of pipe a piece M is secured in the headstock, and carries a cutter N on a moveable slide, which is fed forward by the star wheel O on the screw P, the wheel being rotated by contact with the end of the rod Q, which may be moved into or out of the path of the star wheel. Screws R assist in holding the pipe in position whilst being cut. A presser arm S is held by the lever T against the cutter head to keep it up to its work when cutting screws, and the lever T may be withdrawn from its bearings to allow the arm S to fall and the cutter-head to be removed if required. Claims: The screwing and cutting device as aforesaid; the presser arm and accessories.—No. 15553. October 1st, 1890. 6*d.*

ANCHORS.—*W. L. Byers, Sunderland.*—An anchor designed in the manner described below is intended to be equally trustworthy in mud or slime as in hard ground. To increase the holding power of a stockless anchor the inventor forms a partial cylindrical or curved surface on the inner face or front of the cross-head towards the flukes, the said surface, when embedded in soft ground, affording a firm hold. The curved surface extends longitudinally along the inner part of the cross-head from arm to arm, being partially interrupted at the centre by the double eye which is to receive the shank. The cross-head and spurs are also strengthened by longitudinal and transverse webs formed in one with them, on the underside thereof. Claims: An anchor cross-head, the inner face of which is curved to form a dish or scoop, the underside of the cross-head being strengthened by longitudinal and transverse ribs.—No. 7846. May 20th, 1890. 6*d.*

AIR COMPRESSOR.—*Wm. Tattersall, Bradford.*—The apparatus herein described is for the purpose of supplying compressed air, and is of simple form, consisting of a vibrating compressor blade or vane operated in any convenient manner, and enclosed within a segmental or vee-shaped case provided with suitable valves and a receiver. The blade or vane is pivoted in the narrow end of the case, and the free end of the blade fits against the opposite end of the said case which is formed to a curve struck from the centre of the blade pivot. The inclined sides of the case approach one another at the narrow end, and the parallel sides are the same distance apart as the width of said blade. Admission valves are provided in the casing, at opposite sides of the blade, and emission valves lead from each side into a receiver. In operation, the blade is vibrated within the case by means of connecting rods which are driven from a crank-shaft and vibrate arms, secured, outside the casing, upon the shaft to which the blade is fixed. During each stroke air is admitted to one of the sides of the blade, and expelled from the opposite side, each side serving alternately for suction and for delivery. Claims: The air compressor or blower constructed with a vibrating blade within a vee-shaped chamber, and delivering into a receiver, substantially as described above.—No. 5429. April 10th, 1890. 6*d.*

HIGH SPEED ENGINES.—*W. P. Thompson, Liverpool.* (*Geo. C. Pyle, Indianapolis, Ind., U.S.A.*)—The inventor's object is to construct high speed engines which will automatically maintain an unvarying speed, and which will be compact in structure. Fig. 1 illustrates one of these engines in longitudinal section and coupled

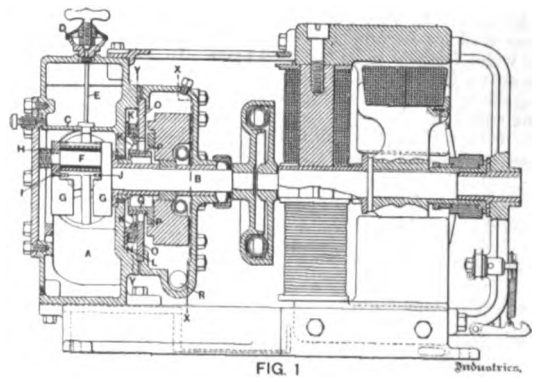

FIG. 1.

to a dynamo, Fig. 2 being a cross section through the cylinders, Figs. 3 and 4 being cross sections on the lines X X and Y Y respectively of Fig. 1. The cylinders A of four single-acting engines are formed in one casting which encases them and carries the bearings for the main shaft B. The two upper cylinders are connected by a web C, the space thus enclosed between them forming a chamber into which oil is introduced at D. The open space around the other cylinders receives the exhaust steam, some of which will find its way up a pipe E and will condense in the oil chamber, displacing some of the oil therein and causing it to overflow down the walls of the pipe E, which will discharge it immediately above the crank pin F; automatic and continuous lubrication is thus ensured, and the chamber is said to act as a steam jacket. The outer web of the crank G is secured to the crank pin F, the latter having its outer end threaded as shown, and being fitted with two bushings H and I, one of which is preferably of a metal which will run without lubrication, this precaution being observed because of the inaccessibility and high speed of the pin. It is considered desirable that there should be three

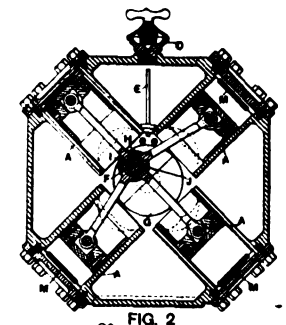

FIG. 2

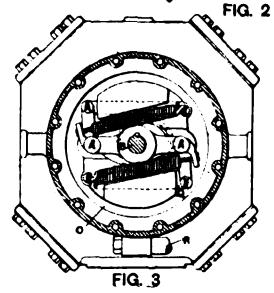

FIG. 3

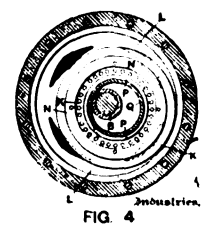

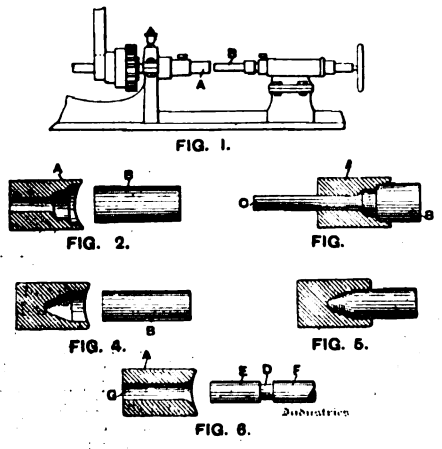

FIG. 4

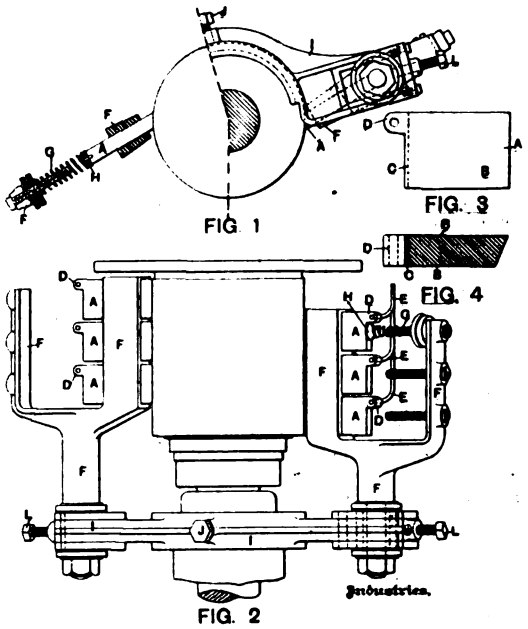
bearing surfaces here—the crank to bear against the first bushing, that against the second bushing, and the latter against the bored big-ends of the piston rods. A ring J embraces the piston rod ends to prevent displacement of same. The valve K is circular in form, and a flat annular portion thereof bears directly against the turned surface L of the bottom of the valve chest and adjacent to the port openings (see Fig. 3); the steam proceeds from these openings along within the thickness of the casting to each cylinder at M; a packing ring N forms the back of the valve, and bears against a stationary ring O which forms a division between the live steam space and the exhaust space. The annular space around the valve and between L and O is the space into which live steam is introduced by a passage (not shown), and the exhaust steam from within the annular valve passes through holes in a flange P into the valve chest, and away by the pipe R. The

Digitized by Google

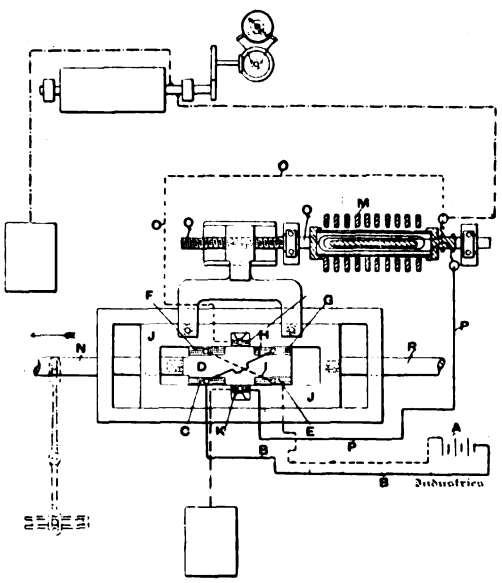
flange P of the valve encircles a similar flange Q, this latter being held eccentrically to the shaft by a centrifugal governor, shown in Fig. 3, operating against the resistance of spiral springs, and carried by the main shaft within the casing; the governor, by varying the eccentricity of the flange Q, lessens the eccentricity of the annular valve, and, the valve and governor revolving with the main shaft and relatively to the port face, variation of the the eccentricity of the valve will vary the point of cut-off and the period of expansion. Claims: The various combinations constituting the high-speed engine as described above, and including the oil chamber and steam jacket, and the valve formed and operated as described.—No. 961. January 20th, 1891. 8*d*.

METAL TUBES.—*J. G. Bohl, Peoria, U.S.A.*—This invention consists in forming tubes and like articles, reducing or increasing their diameter, closing them at their ends, or welding or joining two or more tubes together, as will be described. A hard metal die or former is mounted on the spindle of a lathe and is provided with a smooth recessed face or with a smooth perforation through the die or former in the line of its axis, or with both, as may be required. This recess or perforation receives the tube or other article to be formed, and when the die or former is revolved at a sufficient velocity the article forced thereinto becomes intensely heated by frictional contact, and is thereby softened and made susceptible of being reduced, closed, or otherwise formed. As an alternative the article may be revolved while the die remains at rest, or both may be revolved in opposite directions. Fig. 1 is a side elevation of a lathe for spinning tubes, A being the die or former and B the tube about to be forced thereinto by the tail-stocks crew. In Fig. 2 A is a longitudinal section of a die or former used for forming tubes with small termini, B being the tube which is about to be operated upon. In Fig. 3, the former A is shown in section with the partially reduced tube B therein, C being the reduced portion. Fig. 4 represents in section a die wherein the ends of a tube may be securely closed and welded by means of the tube striking the wall of the recess therein, which heads, closes, and securely welds the ends of the tube, the tube B



being shown in elevation, and in Fig. 5 the die and completed tube are illustrated. In Fig. 6 a die A is shown in which two tubes E F may be welded together. The tube F is represented as slightly larger than the tube E, and as having its end D reduced in order that it may be introduced into the latter as shown. The tubes are now forced into the die A, and the moment the tube F comes into contact therewith it becomes reduced in diameter, and, by reason of the intense heat generated by the frictional contact of the rapidly revolving die is immediately welded to the tube E, and passes out at the opening G reduced to the same size and thickness as the tube E. Claims: The method of spinning and welding tubes and the like substantially as described.—No. 3122. February 20th, 1891. 6*d*.

ELECTRICITY.



SECONDARY BATTERY ELECTRODES. — *Dr. Schoop, Oerlikon, Switzerland.*—According to this specification, electrodes of high capacity for secondary batteries may be produced in a short time at a moderate cost with a minimum expenditure of energy, and without the use of paste or of any material mechanically applied to the body intended to form an electrode. For this purpose one or other of certain electro-negative substances containing one or other of the halogen elements, chlorine, fluorine, bromine, or iodine, are used in a bath in which two series of lead plates are immersed, one set of plates being connected to the positive pole and the other to the negative pole of an electric generator, current being passed through the bath for, say, 36 to 100 hours, in accordance with the strength of current used and the depth of porous lead required. For a plate having a surface of 100 square centimetres, a current of ½ of an ampere may be used, the temperature of the bath being maintained at 50° Fahr., but it is evident that these data are variable with circumstances. An example is given where the composition of the bath is one hundred parts by weight of water, five of bisulphate of sodium, and two-thirds of one part of chlorate of potassium, or an equivalent composed of water, sulphate of sodium, chlorate of potassium, and sulphuric acid; with this bath, there is probably formed on the plate constituting the anode chloric acid, part of which combines with the lead, whilst the other part is decomposed by the current without combining with the lead plate. The result is that oxide of lead is formed upon the anode, and the cathode plate appears to be scarcely altered, hydrogen escaping freely from its surface. After this treatment the direction of the current is reversed, so that the plate which was formerly the anode is now the cathode, and becomes reduced by the oxygen liberated thereon, and is finally covered with spongy or porous lead. When this is effected the bath is removed, the plates washed, and the vessel re-charged with dilute (10 per cent.) sulphuric acid, and another reversal of current is continued until gases are abundantly evolved from each plate, and the two series of electrodes resulting are ready for use. Examples of the use of the fluorine, iodine, and bromine compounds are given. Claims: The electro-chemical treatment above indicated, and involving the use of an electro-negative halogen compound, a salt of sulphuric acid and water, with or without the addition of free sulphuric acid; also the use of a sulphate or bisulphate in this connection.—No. 7518. May 14th, 1890. 6*d*.

BRUSH FOR DYNAMOS.—*M. Immisch, London.*—This is a new form of carbon brush, in which the current is not taken from the frame or holder of the brush, but directly from the carbon block itself, by attaching thereto a flexible conductor. The nature of the invention may readily be gathered from Fig. 1, which is an

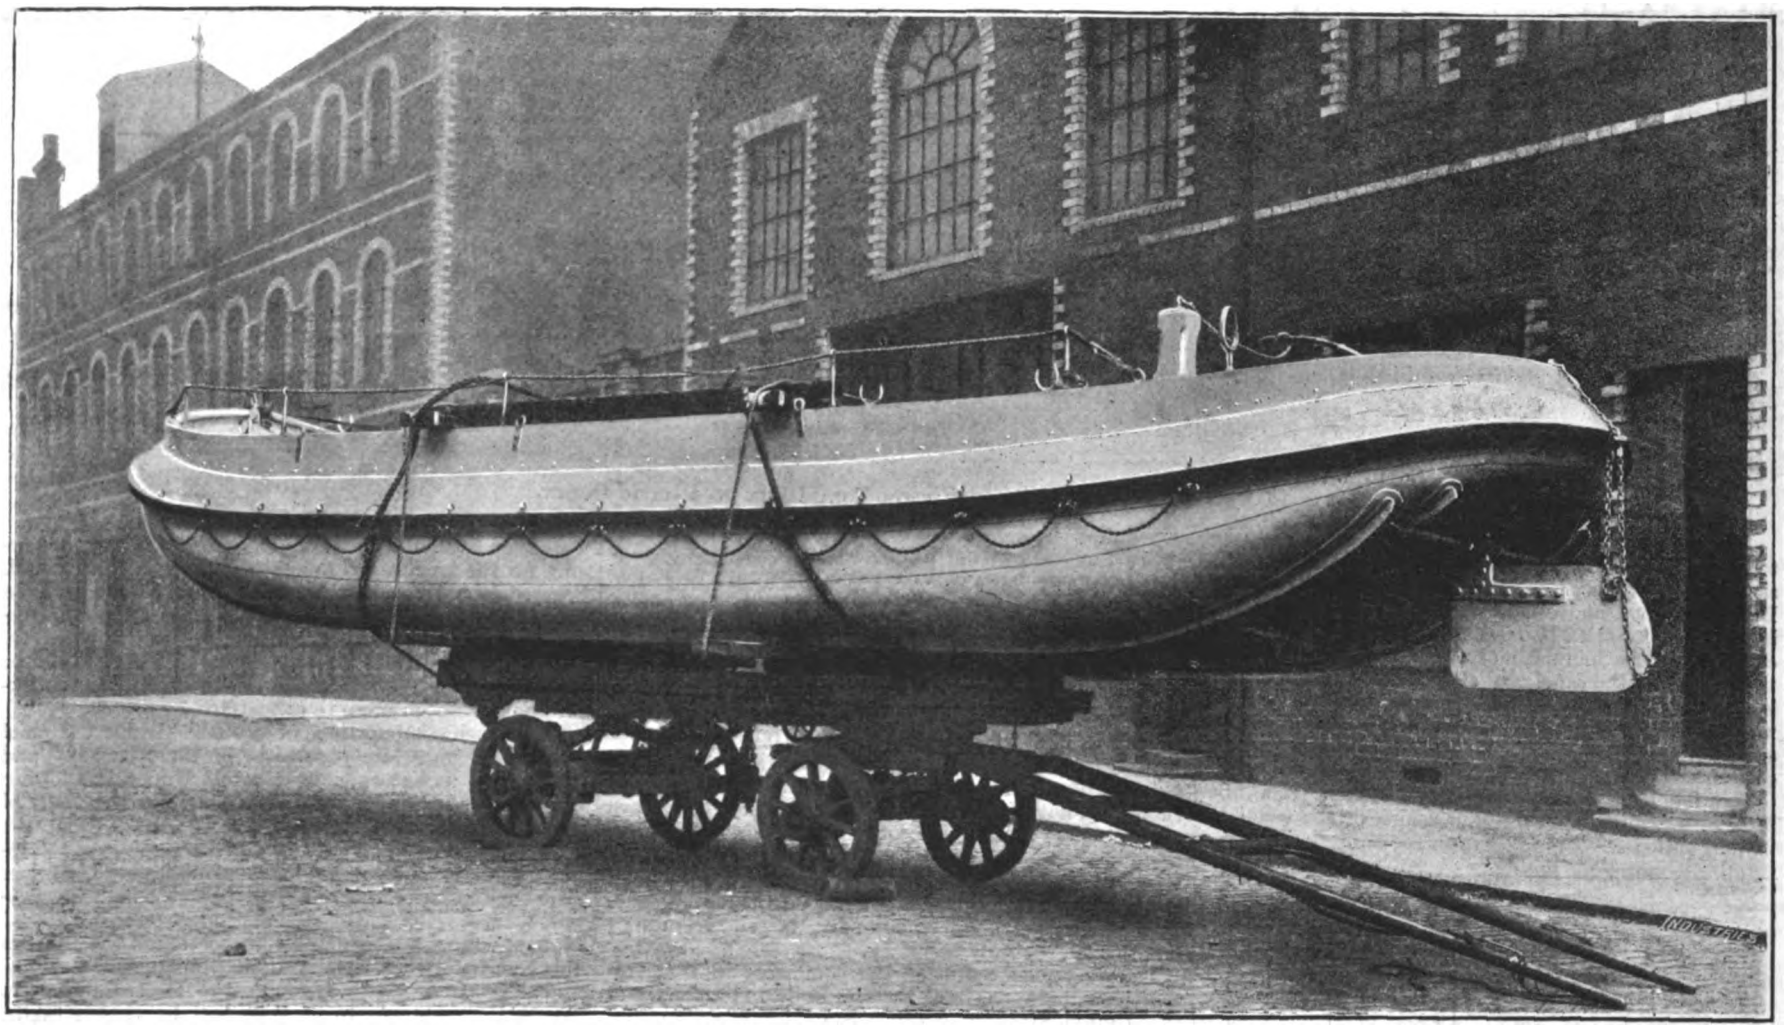
elevation, partly in section, of the commutator and brushes, from Fig. 2 a plan of the same, and Figs. 3 and 4 a plan and longitudinal section, respectively, of one of the brushes. The carbon brushes A are coated with copper B, except at the contact surface with the commutator, and have a plate of copper C secured at the rear end of the carbon block, this plate being provided with an ear or lug D, in which the flexible conductors E are secured to convey the current directly to or from the brushes. The brushes A are inserted in a holder F, through which they can work freely, and adjustable springs G insulated from the brushes by blocks of insulating material H (Fig. 1) enable the pressure of the brushes upon the commutator to be regulated, and allow for the wear of the brushes. Each brush holder F is carried at one end of a frame I, the position of which can be shifted for lead, relative to the end-bearing of the dynamo, and secured by the set screw J, the stems of each of the brush holders F, being, of course, insulated from the frame I, and the brush holders are carried in guides K in the frame I, being adjustable by the screw L towards or from the commutator when the brushes are adjusted for wear or when new ones are inserted. Claims: The brush as described; the insulated spring adjustment for same; and the combination of brushes, holders, and frame.—No. 7511. May 14th, 1890. 8*d*.

SERVO-MOTOR.—*C. W. Sleeman, London.*—This is a combination of sliding contacts carried by two slides, and operated as a "hunting" arrangement for opening and closing a circuit from a

battery through electromotors used to operate signalling devices, such as engine-room telegraphs, or operated by a pendulum for controlling the propulsion of submerged torpedoes, or for other purposes, and the principle of the device is such that, to any amount of movement imparted to the apparatus by the operator, corresponds a certain and predetermined amount of motion of the driven mechanism, correspondence between the two movements being automatically ensured. In the illustration, A is a battery, from one pole of which connection is made by the wire B with a contact C carried by a sliding-block D, which carries also a contact E, and, at its opposite sides contacts F and G. The contacts C and G are electrically connected together by a wire H, as also are the contacts E and F by the wire I. The sliding frame J carries at its opposite sides spring contacts K and L, which are connected to the opposite terminals of a motor M, a wire from the spring contact K going to earth. The operator moves the central slide to any distance to the left of its present position—for example, by means of the screw N, thereby closing the battery circuit through the contact C, wire H, contacts G L, and wire O, to the motor, the return circuit from the motor being closed to earth through the wire P and contacts K. The frame J is operated by a screw Q driven by the motor, which will immediately move the contacts on the frame J away from and ultimately out of connection with the contacts on the block D, which remains stationary. Should the motor over-run, the slide J operated thereby will also over-run (being always operated by the screw Q to follow up the block D), and thus will break the first circuit, bringing the second pair of contacts E and F into position to close a reversed circuit through the motor, which will therefore be rotated reversely, and finally be brought to rest at a position properly corresponding to the completion of the range of motion desired by the operator. The motor M may not itself directly operate the signalling device, which may be arranged in parallel with it as shown in the upper part of the illustration. When used to control a torpedo, the frame J is operated by a pendulum, which acts upon the rod R. Claims: The servo-motor substantially as described for general purposes, and particularly for controlling the propulsion of torpedoes; the use of the apparatus as a relay for connecting an intermediate station with the transmitting and receiving station.—No. 5923. April 18th, 1890. 8*d*.

ZINCS FOR BATTERIES.—*J. Moseley, Manchester.*—The zincs consist of a series of layers or sheets of wrought or rolled sheet zinc, each sheet (when the zinc has to be amalgamated) being separately amalgamated before being made up into the element. In the case of flat and similar elements the several sheets are secured together by zinc fasteners; or, to obviate the possibility of local action arising from differences in the quality of the plates and fastenings, pins or studs of ebonite, celluloid, or similar insoluble non-conductors are employed. In one example, short tubes of ebonite are used, which pass through perforations in the plates, and are slightly longer than the thickness of the element. A warmed conical tool may be inserted in the ends of the tubes to splay or open them outwards and thus secure the plates together. Cylindrical and tubular forms of the elements are shown, in which each of the concentric layers is formed from a tube drawn from a strip of sheet zinc. The edges of the sheet nearly meet, and in placing the tubes one within the other the spaces at such meeting edges should preferably alternately break joint, and in preparing these tubular elements each tube is made of slightly different diameter to that which it will possess when in the element, and the edges are not quite closed up. By this arrangement the tubes may be extended or spring into one another, and will be secured without the necessity for any special fastening. Claims: Battery zincs formed of separate sheets as described, secured by zinc or by non-conducting fasteners; also the tubular and cylindrical battery zincs as described—No. 13463. August 27th, 1890. 8*d*.

CHEMISTRY.



CHROMIUM COMPOUNDS.—*H. H. Lake, London.* (*Jules Massignon & E. Watel, Paris.*)—For the production of the above the inventor, after finely pulverising the ore, mixes it with calcium chloride and lime in such quantities that the entire base obtained from the caustic lime or the calcium carbonate shall be somewhat greater than the quantity necessary for forming a calcium chromate, when all the chromate sesquioxide of the ore will be transformed into chromic acid by the oxidation. The calcium chloride is used in the proportion of one part to three parts of the total lime. The mixture is conveyed to a furnace, wherein it is first heated moderately for effecting desiccation, and is then raised to a temperature sufficient to reduce the calcium carbonate to form caustic lime. If the material burned at the temperature adapted for the reduction of the calcium carbonate is removed from the furnace, it will be sufficient to allow the pieces of material to be exposed to the air at the ordinary temperature in order that the complete oxidation of the chromium sesquioxide shall without any manipulation be gradually effected by the action of the atmospheric air, as the material is porous enough for enabling the latter to pass to the interior of the pieces. For manufacturing chromates and bichromates of potash and soda the above-mentioned mixture is lixiviated in hot water by washing so as to enable a concentrated solution to be produced which contains all the calcium chloride and only a small quantity of calcium chromate by reason of the great difference in the solubility of these two substances. For the purpose of recovering or utilising the calcium chromate entering into this solution, the latter can be concentrated and then serve for preparing a fresh mixture of the material; the calcium chromate which it contains will thus be extracted by the following operation. This solution can be utilised for manufacturing lead chromate (chrome-yellow) by precipitating the calcium chromate by a salt of lead. In this manner will be obtained a solution of calcium chloride deprived of chromate and ready to be used in the operation, and the chrome-yellow is produced very economically, whilst heretofore it has been necessary to obtain the same from potassium or sodium bichromate. After this washing operation the mixture is treated by a solution of sulphate or carbonate of potash or soda and yields potassium or sodium chromate, and if, moreover, sulphuric acid is employed, potassium or sodium bichromate in solution. These solutions are filtered for separating them from the insoluble deposits, concentrated and crystallised in order to extract from them the salts formed. When the mixture of dry oxidised material is treated by sulphuric acid, or by dry gaseous hydrochloric acid, chlorochromic acid can be economically obtained. By treating the mixture with sulphuric acid, and after the calcium chloride has been removed therefrom by lixiviation and after drying, chromic acid can be economically produced without first forming potassium or sodium bichromate as heretofore. The inventor makes six claims for the above-described processes.—No. 2224. February 6th, 1891. 6*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

STEEL TUBULAR LIFEBOAT FOR PWLLHELI.

CONSTRUCTED FOR THE ROYAL NATIONAL LIFEFOAT INSTITUTION BY MESSRS. MECHAN & SONS, NEPTUNE WORKS, GLASGOW.

GENERAL VIEW.

STEEL TUBULAR LIFEBOAT FOR PWLLHELI.

We give above a general view of a lifeboat of a novel design built by Messrs. Mechan & Sons, of the Neptune Works, Glasgow. This boat has been built to the order of the Royal National Lifeboat Institution, from designs prepared by Mr. Charles H. Bloe, M.Inst.C.E., the Honorary Secretary of the Institution at Liverpool. The length of the boat is 35ft.; breadth, 10ft.; depth amidships, 4ft. The hull is formed of two tubes as shown, which taper gradually to a circular section towards the stem and stern, where they turn inwards and upwards toward each other above the water level, thus forming one homogeneous structure. As this boat will require to depend entirely upon oars and sails for propulsion, lightness and strength are essential qualities. With these points in view steel has been adopted for its construction. The hulls are constructed of mild steel plates of $\frac{1}{16}$in. thickness, formed to the required shape and thereafter galvanised. The framing consists of steel angle bars 1½in. by 1½in. by ⅛in., spaced at 21in. centre to centre. The two hulls are securely braced together at intervals under the thwarts by means of girders formed of tee bars of steel. Between those girders and the two hulls the deck is fitted, being supported on the bottom tee bar, while the thwart beams are secured to the upper one of the girder. The tee bars are bound together by struts and ties of steel angle bars. Besides those girders there are three stays 1½in. in diameter, secured to the inside bilge, extending across between the tubes to give additional rigidity to the structure. The deck has a height of about 7in. above the water level, and in it thirty automatic relieving valves are fitted for the purpose of freeing the deck from water as quickly as possible. Around the outside top corner of the tubes, there is secured the gunwale boarding, which is 11in. deep amidships, tapering to 4in. at stem and stern, thus giving the required freeboard of 2ft. 4in. Around the inside of this is fitted the sparred side seats. A central fore and aft beam of red pine is secured along the tops of the thwarts, and a flat steel bar is fastened in the centre line along the bottom of the girders extending from stem to stern. Around the outside of the boat, just above the water level, is fitted an elm rubbing piece to prevent excessive shocks when the boat is alongside of vessels.

The boat is divided by bulkheads into eighteen separate water-tight compartments, so that in the event of several of these being injured, the floating capacity would not be much affected thereby; and for the purpose of cleaning and painting the interior of the hull, a water-tight manhole is fitted to each compartment. In order that the trim of the boat may be under command, a water-ballast tank has been formed on each side, each tank being provided with valves for filling, and a 4in. pump, by which the compartments may be emptied in a few minutes. As the draught of the boat is only 18in., four centre boards, 5ft. long by 2ft. 9in. deep, have been fitted, which will improve considerably the sailing qualities of the boat. Two are inserted into each hull.

It will be evident that a boat having the form described will have very great stability at small angles of inclination, the displacements being divided and removed to a distance from each other. Although, by so doing, the surface friction is increased, this is compensated for by the more important quality of stability.

The boat is fitted with two masts carrying lug sails and one jib sail, and is fitted with accommodation for pulling seven oars on each side. A carriage is provided, which the boat will be launched from, or conveyed by, on land, to within the shortest distance by sea to a shipwreck, thus avoiding danger and enabling the crew to arrive at their destination without being unduly fatigued.

THE NICARAGUA CANAL

IV.

(*Continued from page* 420.)

WATER SUPPLY.

As we have already mentioned, one of the leading points in favour of the Nicaraguan Canal route is the abundance of the water supply at all seasons, in which respect it compares favourably with the Panama route. According to Mr. Menocal's estimate, the water required for thirty-two lockages per diem, corresponding to the passage of 11,680 vessels per annum, would be 127,400,000 cubic feet. The minimum flow from Lake Nicaragua at its outlet by the San Juan River was found, by gauging, to be 11,390 cubic feet per second, or 984,096,000 cubic feet per diem. This gives a surplus of 856,696,000 cubic feet daily over the quantity required, and all from the lake supply only, during the driest season. In the wet season the discharge was estimated by Colonel Childs at 18,059 cubic feet per second, and, taking the mean between the two values, a flow of 14,724 cubic feet per second is arrived at, equivalent to 1,272,530,600 cubic feet daily. On this basis the mean excess of supply over demand would be no less than 1,144,753,600 cubic feet. In addition to this comes the flow of the various tributaries of the San Juan River, and also those of the various basins, which, it is calculated, will amply compensate for leakage and evaporation. The surface area of Lake Nicaragua is about 2,600 square miles, with a watershed of at least 8,000 square miles.

DIMENSIONS OF CANAL.

Out of the 26 miles of excavated channel, over 18 miles of the excavation will be of sufficiently large section to allow vessels travelling in opposite directions

Digitized by Google

THE NICARAGUA CANAL.

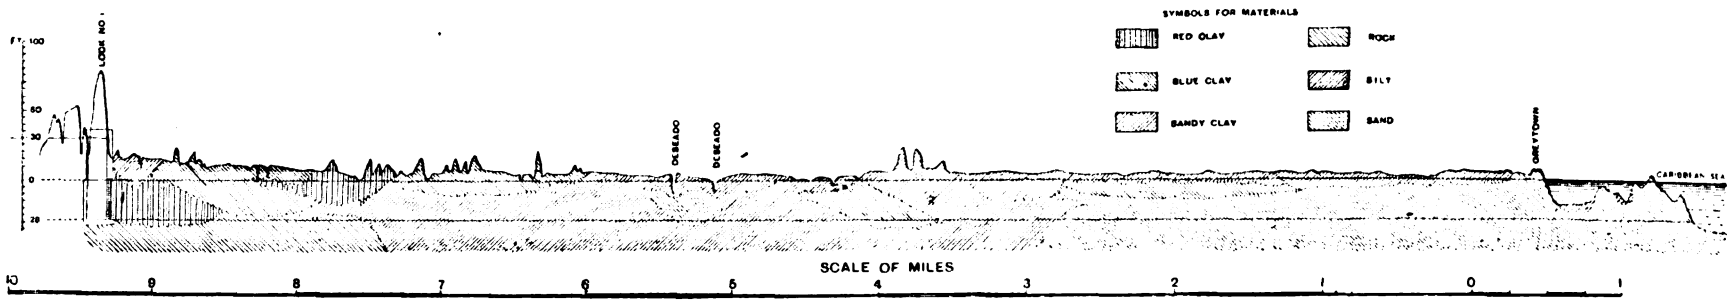

FIG. 7.—GEOLOGICAL PROFILE FROM GREYTOWN TO LOCK NO. 1.

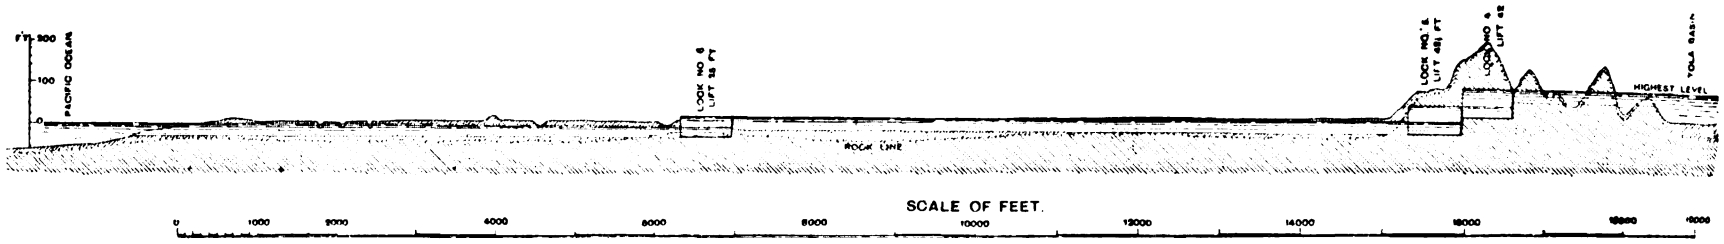

FIG. 8.—GEOLOGICAL PROFILE FROM TOLA BASIN TO PACIFIC OCEAN.

to pass each other. Those parts in which the dimensions will be reduced are in the Eastern and Western Divide cuttings, and consist of a length of 2·917 miles in the former and 4·924 miles in the latter. Here the cuttings will be in rock, and, as they are situated near the termini of the canal, and close to the upper locks, it is considered that the slight gain in speed of transit which would be secured by making the channel of larger sectional area would be outweighed by the increased cost of excavation.

The following tabular statement, taken from Mr. Menocal's report, shows the dimensions of the canal in various parts:—

Portion of Canal.	Length. Miles.	Width, Top. Feet	Width, Bottom. Feet.	Mean Depth. Feet.
Greytown to Lock No. 1	9·297	288	120	28
Lock No. 1 to Lock No. 2 (canal)	1·258	210	120	30
Lock No. 2 to Lock No. 3 (canal)	1·650	210	120	30
Lock No. 2 to Lock No. 3 (basin)	1·762	—	—	30
Lock No. 3 to Western End of Eastern Divide Cut (canal)	2·917	80	80	30

A geological profile along part of the canal is shown above in Figs. 7 and 8, and will, in conjunction with the preceding table, assist in giving a clear idea of the kind and amount of excavation required on the various parts of the canal route.

PROSPECTIVE TRAFFIC.

Last year an elaborate report on the traffic expected to pass through the canal was issued by the Nicaragua Canal Construction Company, compiled by Mr. Thos. B. Atkins, the secretary and treasurer of the Maritime Canal Company of Nicaragua. As the author of this report very truly remarks, the problem is an intricate one, and allows room for a considerable diversity of opinion. The question was very carefully studied by a Statistical Commission for the information of the International Congress which assembled in Paris in 1879 to consider the various projects for an interoceanic canal between the Atlantic and Pacific then before the public. The conclusion was arrived at and embodied in the report presented to the Congress by M. Levasseur, the president of the Commission, "that the tonnage of traffic existing in 1876, within the zone of attraction of such a canal, upon the basis of an estimated average value per ton, was 5,268,000 tons." According to another estimate, based upon statistics partly furnished from American sources, the traffic was calculated at 4,833,000 tons. Finally, 5,250,000 tons was accepted by the Commission as a "very moderate" estimate of the tonnage existing in 1878 within the zone of attraction, while the probable amount in 1888 was calculated at 7,250,000 tons.

In framing a new estimate Mr. Atkins has, in so far as possible, based his calculations on official statistics of value, and not of bulk or weight, since the former are more reliable; where accessible, local statistics have been made use of, otherwise the figures of our own Board of Trade are accepted. The traffic coming within the influence of the canal is divided into three classes—First, entirely tributary; secondly, largely tributary; and thirdly, partially tributary.

The aggregate value of the commerce in 1888, respectively, between Great Britain, France, Germany, and the United States, and other countries, likely to contribute in a greater or less degree to the traffic through the canal, is then given in a tabular form. The total value is estimated at $825,110,167. From the official returns of exports and imports for some of the leading countries of the world an average value of each ton of freight carried can be arrived at, and by applying this value to the whole of the commerce in question—with the exception of nitrates, wheat, &c., which are carried almost exclusively from South American ports to Europe—an estimate is obtained of the equivalent tonnage, which amounts to 18,785,350 tons. The question then has to be answered, as to what proportion of this tonnage will pass through the canal.

As *entirely* tributary, the author of the report in question characterises the trade between the following places:—

	Tons.
Atlantic with Pacific ports, United States, &c. (not included elsewhere)	275,000
Pacific ports with Great Britain, France, Germany, Belgium, Cuba, and Brazil	1,032,247
Atlantic ports of United States with Hong Kong, China, Japan, British Australasia, Philippine Islands, Hawaii, Peru, Equador, and Chili	1,263,399
Coal oil to British, French, and Dutch East Indies from Atlantic ports	519,863
Great Britain with Equador, Peru, and Bolivia	2,137,317
Belgium with Peru	105,589
Total	5,333,415

The trade classified as "largely tributary" is estimated to furnish 2,526,542 tons to the business of the canal, while from "partially tributary" commerce 262,136 tons are expected.

We have therefore:—

	Tons.
Entirely tributary traffic	5,333,415
Largely " "	2,526,542
Partially " "	262,136
Total	8,122,093

This is an estimate for 1889-90, and includes an allowance for the ascertained increase of the trade in coal oil, between the United States and China, Japan, and the East Indies, as compared with the year 1888-89. According to M. Levasseur's report, previously referred to, the anticipated traffic for 1888-89 was 7,250,000 tons, so that it will be seen that the expectations therein expressed have been more than justified by events.

In all such computations of probable traffic the chief element of uncertainty consists in the "largely" and "partially" tributary contingents. Under the former heading, for instance, Mr. Atkins classifies the trade of Great Britain with Hong Kong, Japan, China, the Australian Colonies, New Zealand, Tasmania, the Philippine Islands, Chili, and Central America, and assumes that one-fourth of the total will pass through the proposed canal, being "attracted in proportion to distances." Now, of course, a considerable proportion of the trade of this country with Australia, China, Japan, New Zealand, and Tasmania passes through the Suez Canal. In giving the distances to be traversed by vessels taking different routes between given points, Mr. Atkins states the distances *viâ* the Cape of Good Hope, but not those *viâ* the Suez Canal, and the traffic to the countries above enumerated passing through the Suez Canal is not separated from that carried round the Cape of Good Hope. We think it would be more satisfactory if this had been done, although we have no reason to suppose that Mr. Atkins' estimate is exaggerated, since he expressly disclaims any expectation that any appreciable proportion of British trade with the East and Australia now carried on by way of the Suez Canal will be diverted to the proposed new route.

Generally speaking, it is calculated that where the saving in distance approaches 2,800 miles for a 2,000 ton vessel, with a cargo worth $150,000 or over, there will be an advantage to both shipper and shipowner in using the new waterway at a toll of $2·50 per registered ton. The possible developments of new business resulting from the opening of the canal offer a wide and varied field for speculation, in which Mr. Atkins indulges at some length.

The lumber trade of the North-Western Pacific coast is one of those industries which, it is anticipated, will be greatly increased by the additional facilities for transport to a favourable market afforded by the canal, more especially as the forests of the Eastern States no longer yield an adequate supply of large timber. Another expected result of the construction of the Nicaragua Canal, not altogether so pleasant for this country to contemplate, is the increase of the commerce between the Eastern States of America and South America. "To-day," as Mr. Atkins remarks, "England is practically as near the markets of Western South America as we; to-morrow we shall be 7,000 miles nearer than she is to-day in a distance of 10,600 miles by existing routes. We shall still have the advantage over her of the Atlantic's width when the canal is opened, nearer by so many miles to a market for our cotton goods and manufactures of every kind, with machinery, agricultural implements, furniture, woollen goods, carpets, and coals to sell, and the needs of 75,000,000 of people at home to furnish a reciprocal market for the products which they have to offer us."

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

(*Continued from page* 449.)

REPORT UPON TRIALS OF THE S.S. "IONA."

Duration of Trial.—The duration of the trial from start to finish was exactly 16 hours, or 960 minutes.

Coal Measurement.—The coal was weighed in baskets by means of a spring balance in the stoke-hold, as in the former trials (see *Proceedings*, 1889, page 237; and 1890, pages 205, 214, and 226), about 450lb. at a time being put down on the floor beside each boiler. The trial was started with clean floors, and the time of first stoking from each weighed lot of coal was noted, as well as the time when each weighed lot was completely put on the grates. The line of coal consumption plots out as shown in Fig. 4. As an additional check upon the coal measurement, a particular bunker was emptied beforehand, and coal enough for the trial was weighed into it off the trucks. The amount of coal so weighed amounted to 9·61 tons. At the end of the trial the quantity of coal still left in the bunker was taken out and weighed, and amounted to 2·82 tons, which, deducted from the whole quantity weighed into the bunker, gives 6·79 tons as the quantity used. As the coal weighed in detail during the trial was 6·67 tons, the difference between the two methods of measurement was less than 1¼ per cent. of the whole quantity in the bunker. The fires were cleaned once during the trial. The total amount of ash, weighed after the trial, amounted to 430lb., which is about 2·9 per cent. of the whole fuel used. The coal used throughout was Tyne coal from Walbottle Colliery. Coal samples were taken from the weighed lots frequently during the trial; and after a thorough mixture of all these samples, the final analyses, which have again been kindly made by Mr. C. J. Wilson, are as follows:—

	Coal as used.	Dry Coal.
Carbon	82·34 per cent.	83·97 per cent.
Hydrogen	5·47 ,,	5·58 ,,
Moisture	1·94 ,,	0·00 ,,
Ash	2·90 ,,	2·96 ,,
Nitrogen, sulphur, oxygen, &c., by difference	7·35 ,,	7·49 ,,
	100·00	100·00

A sample of the ash was also collected, and has been analysed by Mr. Wilson as follows:—

Loss on ignition (= carbon)	56·19 per cent.
Mineral matter	43·81 ,,
	100·00

The calculated calorific value of the fuel is 14,830 thermal units per pound, which corresponds to the evaporation of 15·35lb. of water from and at 212° Fahr., and to an equivalent carbon-value of 1·02lb. per lb. of coal. A portion of the coal sample was also tested by Mr. L. A. Legros with a Thomson calorimeter of which gave a calorific value of 14,890 thermal units per lb. as the mean of two separate determinations; the difference between this and the value calculated from the analyses is less than half of one per cent. The total coal used was as follows:—

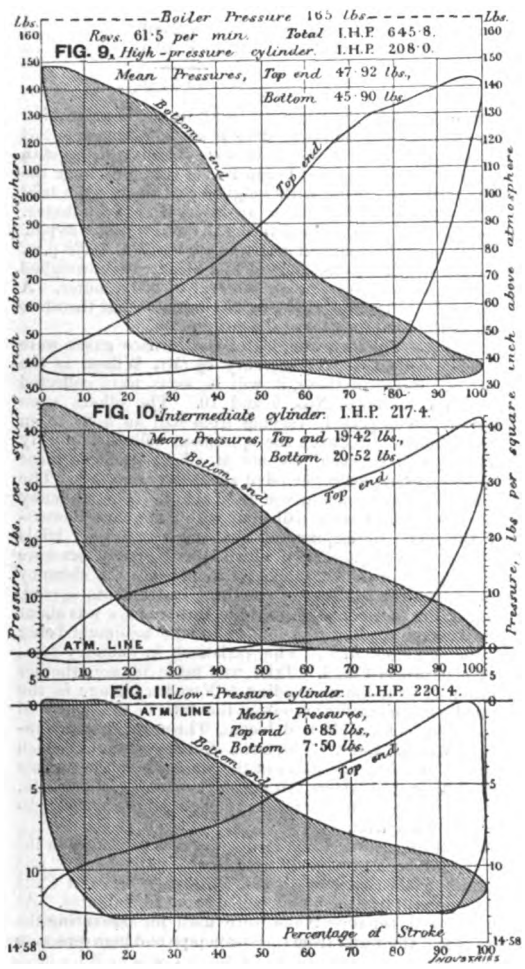
Port boiler	7,248lb.
Starboard boiler	7,701lb.
	14,949lb.

This amounts to 15·71b. per minute, or 942lb. per hour, making a total time for coal consumption of 15 hours 53 minutes, or 953 minutes, which was arrived at as follows:—The last firing with unweighed coal before the trial began was at 6.25 p.m. upon the 13th July, and the last firing with weighed coal during the trial was at 10.21 a.m. upon the 14th, or an interval of 956 minutes. The first firing with weighed coal during the trial was at 6.38 p.m. upon the 13th, and the weighed coal was all burnt at 10.28 p.m. upon the 14th, which was the time of first firing with unweighed coal after the trial was over, or an interval of 950 minutes. A mean between these two intervals, or 953 minutes, has therefore been taken as the total time for coal consumption.

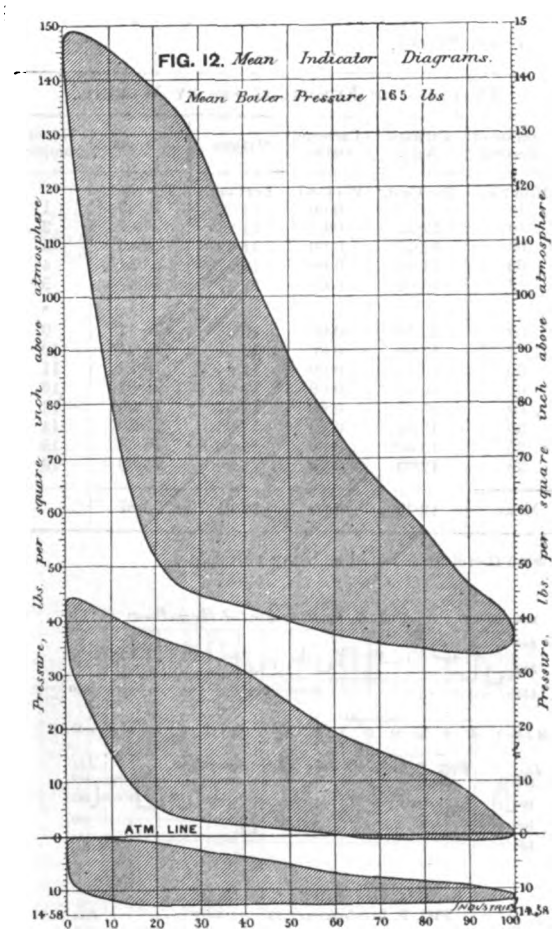
Furnace Gases.—Thirteen samples of the furnace gases were obtained, being collected over mercury by Mr. Wilson as the trial went on. Some of these, it will be seen, were collected quickly, as, for instance, Nos. 5 and 10. The others were collected slowly over periods varying from half an hour to an hour. The differences between the specimens collected quickly and slowly, it will be seen, are not at all so great as those between different samples collected at about the same rate. The analyses of the samples are given in Table I. The chimney temperatures were read every half-hour with a mercury thermometer of the same description as that used in former trials (see *Proceedings*, 1890, page 218). Two Murrie pyrometers were also used alongside of the thermometer to indicate the chimney temperatures, and the readings of the three instruments agreed. The height of the thermometer above the furnace bars was about 30ft. The average reading was 452° Fahr., the minimum being 410°, and the maximum 478°. The variations in chimney temperature are shown in Fig. 4. Trial was made to see whether any alteration of temperature reading followed a change in the position of the thermometer bulb from the side to the centre of the chimney, but none could be detected. The mean air-temperature on deck was 62° Fahr. The mean chimney-draught, which was measured by a U gauge-glass at the place where the furnace gases were collected, or about 13ft. above the damper, was 0·25in. of water. The funnel damper was only one-sixth open throughout the whole of the trial.

Feed-water Measurement.—The feed water was measured in the tanks which had been previously used in the "Colchester" and the "Tartar" trials (see *Proceedings*, 1890, page 219, and Plate 87). In the present trial each tank lasted about 15½ minutes. As already mentioned, separate tanks were used for measuring the jacket water and the water from the steam pipe and high-pressure valve chest drains, and a third separate tank was used for measuring the supplementary feed water. The water from the hot well was pumped into the measuring tanks by a donkey pump which was supplied with steam from the donkey boiler. This arrangement was adopted in order to prevent the additional load which would have been thrown upon the air pump if it had had to deliver into the measuring tanks. The feeding of the main boilers was done entirely by the engine pumps, which drew the water from the measuring tanks. The glands of the feed pumps leaked considerably during the first hour and a half of the trial; but the leakage was then so far stopped that it could be neglected during the rest of the trial. Steam was kept up in the donkey boiler for the fan engine, the donkey pump already mentioned, and the ballast donkey. The total amount of water used was 136,820lb. during a total time of 953 minutes. This amounts to 143·6lb. per minute, or 8,616lb. per hour. The rate at which the feed water was supplied and the variations of its temperature are shown in Fig. 4. Both at the commencement and at the end of the trial the boiler pressure was falling, as will be noticed from the diagram Fig. 6, and the water level was as nearly as possible the same; but the motion of the vessel at the end of the trial made the last observation of water level a little uncertain. An error of ½in., however, which is certainly more than could have occurred, would make a difference of less than 0·4 per cent. in the total feed, and might therefore be practically neglected. At 5 a.m. on 14th July samples of water were taken from both boilers, and at the same time a quantity of steam from the main steam pipe was condensed and collected. These samples were analysed by Mr. Wilson to determine the percentage of salt present in each, and gave the following results:—

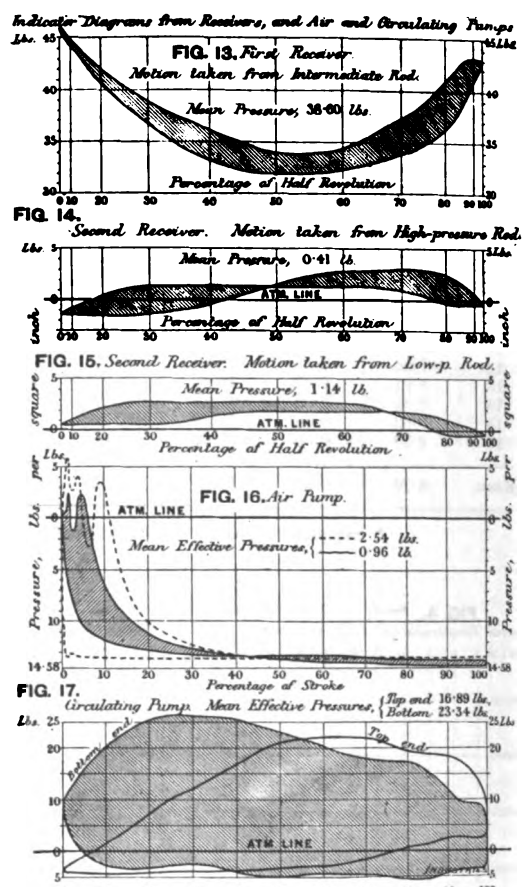
Sample.	Percentage of Salt Present.
From steam pipe	0·00758 per cent.
,, starboard boiler	0·351 ,,
,, port boiler	0·177 ,,
Mean of both boilers	0·264 ,,



Taking the average saltness of the water in the two boilers this shows that the above sample of condensed steam contained 2·87 per cent. of boiler water, which figure therefore represents the amount of priming at the time when the sample was collected. It was intended to have taken a series of these samples throughout the trial; but unfortunately the condensing apparatus broke down, and the above sample was the only reliable one that was obtained. The temperatures of the circulating water and of the discharge water were measured at about half-hourly intervals throughout the trial. Calculating from these observations, the mean temperature of the circulating water was 55·8° Fahr., and of the discharge water 75·5° Fahr.



Additional Water Measurements.—The total water taken from the high-pressure jacket over a period of 910 minutes was 5,600lb., being at the rate of 6·15lb. per minute, or 4·3 per cent. of the total feed. The total water from the steam-pipe and high-pressure valve chest drains during 910 minutes was 800lb., or 0·88lb. per minute, which is 0·61 per cent. of the total feed. The total amount of supplementary water was 8,302lb. in 953 minutes, being 8·7lb. per minute, or 6·1 per cent. of the total feed. Practically the whole of the water from the jacket and cylinder drains was returned into the feed measuring tanks, and therefore repumped into the boilers.



* Report prepared by Professor Alexander B. W. Kennedy, F.R.S., Chairman of the Committee, for the Institution of Mechanical Engineers, and read at the meeting of the Institution on the 31st ult.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.

Power Measurement.—Indicator diagrams were taken every half-hour from each end of each cylinder, as in the former trials. There were thus 32 complete sets of diagrams, or 192 single diagrams, taken in all. The indicators used were again kindly lent by Messrs. T. S. M'Innes & Co., of Glasgow, and were the same that had been in use in the trials of the "Colchester" and "Tartar" (see *Proceedings*, 1890, pages 219 and 231). The springs used were in most cases new, and had all been carefully tested before the trial. The following are the mean effective pressures in the cylinders in lbs. per square inch:—

Cylinder.	Top.	Bottom.	Mean.
High-pressure...	47·98 ...	45·32 ...	46·65
Intermediate ...	20·52 ...	20·36 ...	20·44
Low-pressure ...	6·80 ...	7·52 ...	7·16

These pressures correspond with the following indicated horse-powers:—

High-pressure cylinder.....	205·6
Intermediate cylinder	221·2
Low-pressure cylinder.....	218·6
Total indicated horse-power	645·4

The maximum indicated horse-power given by any one set of diagrams was 667·9, which occurred at 8.15 a.m. on 14th July, with 61·3 revolutions per minute, and boiler pressure of 163lb. per square inch. The minimum indicated horse-power by any one set of diagrams was 627·5, at 7.15 p.m. on 13th July, with 61·4 revolutions per minute, and boiler pressure of 162lb. per square inch. In Figs. 9, 10, 11 is given the set of diagrams nearest to the mean, which was taken at 10.45 p.m. on 13th July, with 61·5 revolutions per minute, and boiler pressure of 165lb. per square inch. From the 192 diagrams which were taken during the trial a mean diagram has been plotted for each of the three cylinders, and these are given in Fig. 12. Eight diagrams were taken from the circulating pump during the trial, four from each end, and examples of these are shown in Fig. 17. The average power given by these diagrams is 12·4 i.h.p. at the mean speed of 61·1 revolutions per minute. Six diagrams were taken from the air pump, which is single-acting, and examples of these are shown in Fig. 16. The average power given by these diagrams is 1·2 i.h.p. at the mean speed of 61·1 revolutions per minute. Several diagrams were also taken during the trial from the first receiver, the indicator barrel being actuated from the cross-head of the intermediate cylinder; from the second receiver when the barrel was actuated from the low-pressure cross-head, and again when it was actuated from the high-pressure cross-head; and also from both ends of the condenser. Examples of the receiver diagrams are shown in Figs. 13, 14, and 15; the condenser diagrams are merely horizontal straight lines showing a mean absolute back-pressure of 1·2lb. per square inch. The continuous variations of boiler pressure are shown in Fig. 6, of cylinder mean effective pressures in Fig. 8, of horse-power in Fig. 5, and of speed in Fig. 7.

Speed.—The counter was read every half-hour. The total number of revolutions made was 58,651 in sixteen hours, giving an average speed of 61·1 revolutions per minute throughout the trial. The maximum number of revolutions per minute for any half-hour during the trial was 61·8, and the minimum 59·7 revolutions. The continuous increase of total revolutions from the beginning of the trial is shown in Fig 4.

Pressures, &c.—All the pressure gauges connected with the engines and boilers were checked by means of a standard gauge, and a correction allowed for where necessary. The mean barometric pressure during the trial was 29·67in. of mercury, or 14·58lb. per square inch. The mean boiler pressure was 165·0lb. per square inch above the atmosphere by the pressure gauges in the engine-room. The mean pressures in the high-pressure valve-chest, first receiver, and second receiver were respectively 160·0lb. and 41·7lb. and 2·4lb. per square inch above the atmosphere. The mean vacuum in the condenser was 28·25in. of mercury by gauge, which corresponds with a mean absolute back pressure in the condenser of 0·70lb. per square inch. The mean pressures in the first and second receivers, as measured from the indicator diagrams taken, were respectively 38·0lb. and 0·6lb. per square inch above the atmosphere; and the mean absolute back pressure in the condenser, as measured from the diagrams, was 1·0 forward and 1·4 aft, or a mean of 1·2lb. per square inch. The mean initial pressure in the high-pressure cylinder, as measured from the diagrams, was 142·5lb. per square inch above the atmosphere; and the mean vacuum in the low-pressure cylinder, as measured from the diagrams, was 12·74lb. per square inch, which corresponds with a mean absolute back-pressure of 1·84lb. per square inch in the cylinder.

Boiler Efficiencies.—The mean rate of combustion in the furnace was 22·4lb. of coal per square foot of actual gratesurface per hour, or 0·30lb. per square foot of total heating surface per hour. The total amount of feed-water pumped into the boilers, as given in an earlier paragraph, corresponds with 9·15lb. per lb. of coal. The average temperature of the feed was 106° Fahr., and the temperature corresponding with the mean boiler pressure was 373° Fahr.; so that each lb. of steam must have taken up (212 − 106) + 966 + 0·305 (373 − 212) = 1,122 thermal units. The equivalent evaporation from and at 212° Fahr. was therefore 10·63lb. of water per lb. of coal, or 10·42lb. per lb. of carbon-value in the coal. The equivalent amount of heat utilised per lb. of coal would be 10,265 thermal units, or 69·8 per cent. of the thermal value of the fuel. This figure of course represents the actual boiler efficiency. The series of analyses of chimney gases given in Table I. enable the weight of the air used per pound of coal to be calculated. The weight of dry air per lb. of coal thus worked out amounts to 24·51b., so that the total weight of furnace gases per lb. of coal would be about 25·4lb. These gases have been raised in temperature from 62° Fahr., the temperature of the outer air, to 452° Fahr., the mean chimney temperature. Taking the mean specific heat of the gases as 0·243, this corresponds to a loss of 2,407 thermal units per lb. of coal, or 16·2 per cent. of the whole calorific value of the fuel. In estimating the weight and specific heat of the gases, it has been assumed that the whole of the hydrogen in the fuel was burnt. No doubt this is not an entirely correct assumption, but the error due to it is very small. The loss due to the evaporation of the moisture in the fuel is so small that it may be neglected; and in no one of the thirteen analyses was any carbonic oxide found to be present in the gases. The quantity of heat not accounted for is, therefore, 14·6 per cent., which is mainly covered by the radiation, but includes also any losses due to unburnt carbon passing up the chimney, and to imperfect combustion of the hydrocarbons, &c. The weight of air theoretically necessary for the complete combustion of 1lb. of coal is 11·4lb. The air actually used is, therefore, about 2·15 times the amount theoretically required. The weight of water evaporated from and at 212° Fahr. per square foot of total heating surface was 3·171b. per hour. The average rate of transmission of heat through the material of the boiler was 3,059 thermal units per square foot of heating surface per hour.

Coal Consumption.—The total coal burnt—namely, 942lb. per hour—corresponds to 1·381b. per indicated horse-power per hour. This is equivalent to 1·491b. of carbon-value per indicated horse-power per hour.

Engine Efficiencies.—The total indicated horse-power being 645·4, and the total feed-water used per hour being 8,616lb., the feed-water used per indicated horse-power per hour was 13·351b. The actual heat received by the feed-water per minute was 161,100 thermal units, or 249·6 thermal units per indicated horse-power per minute, which is 69·2 per cent. of the whole heat of combustion. The absolute engine efficiency, or ratio of the heat turned into work to the heat given to the feed-water, was 18 per cent.

Total Efficiency.—The combined efficiency of the boilers and engines, or ratio of the heat turned into work to the total heat of combustion of the fuel, was 0·74 × 0·171, which is equivalent to 12·55 per cent.

Steam from Indicator Diagrams.—The following are the results of measurements made upon the indicator diagrams taken to ascertain the proportion of steam accounted for by them. The actual weight of feed-water used per revolution was 235lb.:—

Proportion of Steam accounted for by Indicator Diagrams.	Lbs. per Revolution.	Percentage of Total Feed.	Percentage in Jacket or present in Cylinder as Water.
	Lbs.	Per Cent.	Per Cent.
Steam present in high pressure cylinder after cut-off, when the pressure was 125·4lb. per square inch above the atmosphere.....	1·49	63·4	36·6
Steam present in intermediate cylinder, when the pressure was 19·4lb. per square inch above the atmosphere	1·76	74·9	25·1
Steam present in low-pressure cylinder near end of expansion, when the pressure was 8·6lb. per square inch below the atmosphere..... ...	1·39	59·1	40·9

(To be continued.)

SHAW'S "PNEUMATIC BRIDGE."

THE pneumatic bridge is an instrument invented by Mr. W. N. Shaw, of Emmanuel College, Cambridge, for comparing the capacity which different orifices and tubes possess for transmitting air. It was described in a paper read at the recent meeting of the Physical Society at Cambridge. By its means it is possible to study the relative advantages of systems of ventilation and other questions connected with currents of air, for the readings of the instrument are directly and accurately proportional to the quantities of air delivered. Such an instrument has long been desired in the scientific study of ventilation, where the measurements have been generally made with anemometers.

Those of our readers who are acquainted with the Wheatstone bridge method of comparing the resistances offered by wires to the electrical current will readily follow the theory and working of this new bridge, for it bears a strict analogy to that instrument. It, as at present constructed, consists of three air-tight boxes, one of the size of 4ft. by 1½ft. by 1½ft., and two of the size of 3ft. by 1½ft. by 1½ft., arranged and fastened together in a manner shown in Fig. 1. In the middle of the upper side of the transverse box is a metal chimney containing a gas flame, by means of which the necessary draught is obtained. This flame can be altered in size so that the head of air may be made greater or less. It has been found that in this particular instrument the head can be varied in the ratio of 4 to 1. To obtain a greater draught a revolving fan can be used. Between the transverse and the two lateral boxes are two equal openings C and D of about 1½in. diameter, and it is through them that the air is drawn from the side boxes. They are circular openings cut in the thinnest possible sheets of mica, and represent in the electrical analogue two equal resistances. At a point 1ft. distant from the far ends of the side boxes is a glass tube about 1·1in. in diameter, connecting them, and in it at its centre is a small magnetic vane G (Fig. 1). As the sensitiveness of the apparatus depends on the indicator employed, we shall quote Mr. Shaw's description of it. "The one tried and found to work well consists of two very small parallel sewing needles, stuck through a cap of elder pith, supported on a small agate compass centre. The needles carry very light mica vanes on one side of the centre, counterpoised by a small quantity of platinum wire. The whole is balanced on the point of a fine needle, and forms a very delicate wind vane." The needles are magnetised and maintained in a fixed direction by an external control magnet, so that their points are opposite a fiducial mark in the glass tube. The sensitiveness can be altered as desired by the external control magnet just as that of a galvanometer needle can be.

One foot nearer are two other orifices A and B (Fig. 1), one of which is a graduated and adjustable slit shown in Fig. 2, and the other is the particular orifice or tube of which the air transmitting capacity is required. F is an additional aperture for other experiments. The two openings A and B are analogous to the other two resistances in Wheatstone's bridge, one of which is a known variable, and the other the resistance to be determined.

Let us trace now the passage of air through the instrument due to the draught in the chimney. It will enter by the orifices A and B in proportion to their capacities, and if they are exactly equivalent to one another in exactly equal quantities. It will then pass through the side boxes to the two orifices C and D, and through them pass into the transverse chamber to the chimney, since C and D have equal transmitting capacities. But if the quantities entering A and B are not the same, then part of the air from that side on which more is admitted will find its way by the glass tube to the side where less enters, and in doing so will deflect the vane in the opposite direction to its motion like a weathercock. If the experimenter now alters the adjustable slit A until the vane returns to its position of rest, he will have restored equilibrium between the currents. The orifice at B can now be changed for another, and the adjustment again made. In this way the comparisons we are about to describe have been made.

At the meeting of the Physical Society at Cambridge, on the 9th inst., Mr. Shaw exhibited a piece of ordinary sheet zinc with a circular hole cut in it, having a slight bevel on one edge. He explained that it was some 10 per cent. better as an air transmitter when placed with the bevel outwards. This same result was shown in another way: two equal sized tubes of wood, shown in section in Fig. 3, were compared, one ending with a flush edge and the other ending in a trumpet. The latter was nearly a half again as efficient as the former. This advantage of trumpet-shaped orifices is used on steamships where the ventilators for the engine-rooms are expanded into large trumpets which can be turned towards the wind. The explanation of the increased capacity depends on the prevention of small vortices which occur just inside a tube with a flush end, there being the same formation of

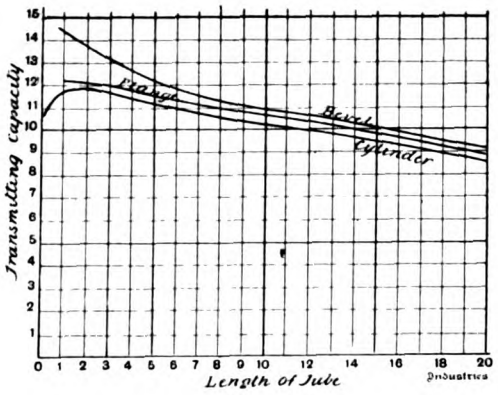

FIG. 5.

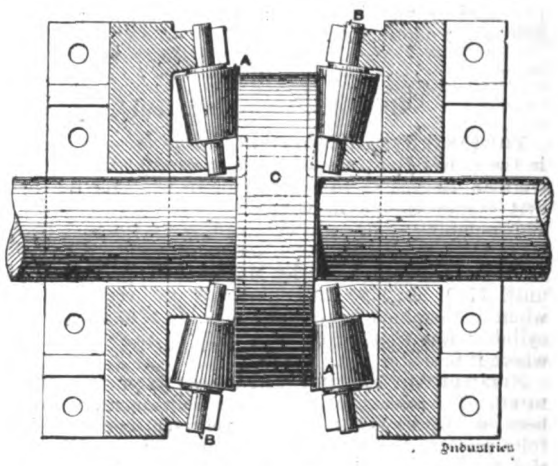

a contracted vein with air as there is in an ordinary water jet.

The comparative efficiency of different lengths of a cylindrical tube ending flush, with a flange and with a bevel, is exhibited in the diagram Fig. 5, where horizontal distances represent increasing lengths of tube and vertical distances represent transmitting capacity. It will be noticed that, with the adjustable cylindrical tube represented in Fig. 4, the first small length placed in front of a circular aperture has the effect of increasing the quantity of air admitted. Further increase of length of the tube reduces by friction the capacity for transmitting air. Another result which has been established by experiments with the bridge is that two circular apertures in a thin plate of mica are precisely equivalent to one circular aperture whose area is equal to the combined area of the two.

Many useful applications for this instrument will suggest themselves. Various ventilators might be compared by attaching small models to the bridge, and the friction in chimneys and cowls might be determined. It would also be serviceable in directly comparing gas meters. If water were the fluid used in place of the air, many other applications may be found. Plumbers would find it useful in comparing the effect of bends, stops, and cocks; whilst the hydraulic engineer could test the efficiency of waterways. For this purpose Mr. Shaw has suggested the use of two canal locks connected by a cross channel.

THRUST BEARING FOR PROPELLER SHAFTS.

WE illustrate herewith in section a thrust bearing for propeller shafts, which is designed to overcome some of the difficulties arising from the ordinary type. It consists of two series of rollers A, one on each side of a collar C, formed on the propeller shaft. The rollers are made from hardened steel, and are fixed on spindles B, which revolve in bearings formed in the thrust-block.

It will be noticed that the rollers are frustra of cones, and are so carried in the thrust-block that their surfaces are in a plane coincident with that of the face of the collar against which they press. It is claimed for this bearing that it overcomes entirely the objections to the use of spheres, and that rollers of the shape shown are very readily and accurately obtained. There is, moreover, no contact between adjacent rollers, and the only frictional surface is that of the spindles.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 19th May, 1891.

The Iron Market.—The Paris market is still very firm, with a strong tendency to a still further rise in prices. The state of affairs in Belgium has a certain influence on quotations here, but apart from this cause the iron trade in France is, at all events for the moment, fast gaining strength. The building business in and around Paris is very active, and the demand for iron work for constructive purposes is very great. Prices are very firm at 136s. 6d. per ton for bars, and 144s. 6d. per ton for joists. There is a healthy tone in the provincial markets generally. Mr. Jules Weitz, of Lyons, has received an order for 7 kilometres of 50 centimetre gauge portable railway, with 40 turntables and 400 waggons, from La Société Française des Charbonnages du Tonkin. La Société des Fonderies et Hauts Fourneaux de Pont-à-Mousson, Meurthe-et-Moselle, has secured a contract for the supply of about 3,000 tons of cast-iron piping for the Paris water supply, to be delivered within three years, at an average price of 130s. per ton.

Champagne Annual Statistics.—Messrs. J. R. Parkington & Co. state that the total quantity of champagne forwarded from the champagne districts for the year ending March 31st amounted to 25,776,194 bottles (the largest quantity on record), being an increase of 2,451,623 bottles, as compared with 1890. Present stocks in cask and bottles amount to about 110,256,000 bottles, or about five years' consumption.

Tancarville Canal.—All the works in connection with the Tancarville Canal are now completed, with the exception of some dredging at its entrance into the River Seine. The tonnage of merchandise in this canal has increased from 239,009 tons in 1888 to 302,120 tons in 1890. Before this canal was made the amount of goods brought to or taken from Havre by the river in barges did not average more than 170,000 tons a year.

An Electrical Mining Plant.—The Compagnie Continentale Edison installed an electric haulage plant at the end of last year in the Mines de Marles, and it has given such satisfaction that the original plant is now about to be considerably enlarged. The generator is a 26 unit Edison machine, giving 400 volts at 900 revolutions. The pit is nearly 1,000ft. deep, and the line runs along a gallery 1¼ miles in length. The locomotive is 7ft. 3in. long, 2ft. 4in. broad, 4ft. 11in. high, and weighs 2 tons 6 cwt. The motor is a 10 unit machine, and is arranged lengthwise. A speed of over 9 miles an hour is attained, and 10 b.h.p. is developed when hauling a train of twenty-five fully loaded skips, each weighing 14 cwt. The conductors in the gallery are two suspended Vignoles rails having porcelain insulators fixed in the roof, and the current is taken off by travelling carriages fitted with brushes and connected to the locomotive by flexible conductors.

Extended Use of the Telephone.—A company has been formed in Paris to organise a telephonic theatrical service. The company has erected in various public places, such as cafés, clubs, restaurants, &c., a certain number of automatic telephone receivers, by which, on introducing a fifty centime piece, one is placed in communication for five minutes with the theatres or concerts indicated on the apparatus. At present the Opéra Comique, the Bouffes, and the Nouveautés are the only theatres in connection with the system, but the number will be soon increased.

Launch.—On the 9th inst. the "Forges et Chantiers de la Méditerranée" launched a steel twin-screw steamer of about 4,000 i.h.p. for the Channel service between Newhaven and Dieppe, in connection with the Western Railway Company. The vessel is designed for passenger service only, and will make the passage in about 3¼ hours. Her principal dimensions are:—Length, 269ft.; breadth, 29ft. 6in.; depth, 15ft.

BERLIN, 18th May, 1891.

The First Steam Engine in Germany.—At Hettstedt, in the Lower Harz, a monument, erected by the Society of German Engineers to commemorate the erection of the first steam engine in Germany, was recently unveiled. This pumping engine was obtained by the Prussian Government from England in 1788, and continued to be used for raising the water from the Mansfeld copper shale mines until 1789. In 1795 the engine was removed to Löbejün, where it remained in use until 1848. In 1867 the old steam cylinder was transferred to a mine in the same district, where it is still in use.

Electrical Testing Establishment at Magdeburg.—The electrical testing establishment, which has been in operation for nearly a year, has continued to be fully employed up to the present time. Like the association for the inspection of boilers, it undertakes to make for its members yearly inspections of electrical installations. In this way it has accomplished very useful work for the owners of electrical works. Its influence has been the more powerful in consequence of the fact that it is entirely independent of electrical firms, and can therefore give an unbiassed opinion. The activity of this establishment is felt throughout the whole of Germany. Its work consists in examining and reporting on the estimates for electrical installations. It affords advice and information concerning electrical apparatus, and gives its members by means of circulars the benefits of the experience which it has gained in carrying out the inspections.

Electrical Elevators and Cranes.—The Allgemeine Electricitäts Gesellschaft has obtained good results by the use of motors for elevators and cranes. For some time past the company has worked an electrical elevator for raising coal. The waggons when filled are pushed on to the cage. A full load of a ton can be raised 30ft. in about forty seconds. As the cage rises it automatically shuts the safety gates which the waggon had opened on its way down. The winding engine is automatically put out of gear when the cage reaches either end of its course. The waggon on coming to the surface is received by a powerful crane, which is put into connection with the current as soon as the winding engine stops. The electromotor is not used in the return journey, as the waggon runs back by its own weight with a regular speed. The installation is provided with safety apparatus in the event of the breaking of the rope or of the pulley, and the cage on breaking away can only attain a speed of one metre per second. Electromotors are specially useful for working cranes, as it often is difficult to apply steam power where the cranes are to be used. Electromotors can be advantageously used for travelling cranes in workshops, as their control is very simple. The same company has had two travelling 1-ton cranes at work for some time now.

VIENNA, 18th May, 1891.

The Iron Market.—No important change has taken place in the iron market since my report of last week. There are, however, many signs that an improvement of the situation may be looked for. Building operations are in very active progress in the two principal towns of Austria-Hungary, and a revival of all the building trades and industries connected therewith is expected. The property of all the mining and iron companies shows a continual rise in value, which may be attributed to the fact that the profits of working are more favourable than those of the previous year. Last week the balance-sheet of the Alpine Mining Company, which had been awaited with some interest, was published. The net profits for the past year amounted to £284,631. It was decided to pay a dividend of 5½ per cent., and to assign the balance, £155,000, partly to the tontines, and partly to next year's account.

The Coal Market.—Notwithstanding the advanced season there is no alteration in the state of the coal market. Last week the market was affected by the strikes, which began on the 1st inst. in the Bohemian brown coal works and in the Ostrau district. About 8,000 men went out on strike.—The Rossitz Mining Company has had a larger output last year than in any previous year. The dividend was equal in value to 27,200 waggons of 10 tons each, and the net profit amounted to £26,157, which allows the payment of a dividend of 5½ per cent.

Electrical Engineering.—The electrical railway, projected by Messrs. Ganz & Co., and having a speed of 28 miles per hour, is to be worked by means of a distribution of current, which has been specially devised by Mr. Zipernowski. The current is sent from the alternating machines at the central station to the secondary stations at a pressure of 10,000 volts, where there are machines consisting of a combination of alternate current motors and continuous current dynamos. The alternating current motor at the secondary station drives the dynamo, which produces a continuous current for working the motors in the carriages. By means of this combination the alternate current motor of the secondary stations is at first driven by the continuous current dynamo, until it attains synchronism, when the motor drives the dynamo. Since the alternating current motors work at some loss with full load, Mr. Zipernowski has devised this ingenious means of utilising both systems of current for distant portions of the line.

Silk Culture.—Recently published statistics show that the expansion of silk culture in Hungary during the last decade has been very great. In the year 1880 there were 1,059 silk growers in 172 towns, who produced 10,132 kgr. of fresh cocoons. This number has increased to 66,525 growers in 1,942 towns, with an aggregate production of 1,043,906 kgr. These magnificent results were brought about by establishing mulberry tree plantations, by distributing trees and plants, and by careful selections of seed in specially sericultural stations.

BRUSSELS, 19th May, 1891.

Iron and Steel.—A very large number of industrial establishments are stopped, some on account of the strike and others for want of coal, a supply of which is expected in a few days. In the battery of Liège, in the iron manufactory the blast furnaces are stopped, and the want of coal impedes labour. The workmen of this city continue to strike, and certain works will be awkwardly fixed, as they have deliveries to make at fixed terms. There is therefore nothing particular to report in the way of progress, the prices of iron remaining feeble.

Coal Trade.—The strike is general in the coal trade, but there is a tendency to relax. The country is visited by a large number of agents, who offer English, German, and French coals. The question is, therefore, for the Belgian coal owners to decide whether or not the fuel is to be brought from foreign countries.

Electric Lighting.—This branch of industry is also suffering by reason of the strike, the most important cafés and theatres having to cease the use of electricity for lighting purposes.

DÜSSELDORF, 19th May, 1891.

The Iron Market.—On the whole there seems to be a gradual improvement in the iron market of this district. There is, however, still no advance in pig iron. For rolled iron there is an increased demand, and the works are more fully employed than during the first quarter. The iron plate trade is still unsatisfactory. Iron pipe works have had many difficulties to contend against during the past few months. Railway waggon works have been well employed at remunerative prices. A meeting of representatives of rolling mills employed in the manufacture of thin sheets took place at Geisweid on the 6th inst. It was decided to form a union among the owners of rolling mills in Silesia, the Rhine district, and the Siegen and South German districts.

The Coal Market.—Although the demand for coal in Germany has fluctuated much during the past few years, the production, on the whole, has considerably increased. The output rose from 42 million tons in the year 1880 to 59 million tons in the year 1888. Germany, therefore, ranks second in the coal-producing countries of Europe. As compared with the English production it is, however, unimportant. The strike of coal miners must be regarded as completely at an end. The general condition of the coal market is now firm. The deficiency in the output this year corresponds to the output made by one workman in 110,225 working days. As each workman produces an output of ·9283 tons per day, the total deficiency amounts to 102,321 tons. Prices are as follow:—Gas coal, 11s. 9d. to 12s. 3d. to 12s. 9d.; rough coal, 8s. 10d. to 9s. 4d. to 10s. 2d.; lump coal, 11s. 9d. to 12s. 3d.

AMSTERDAM, 18th May, 1891.

Dutch General Tramway Company.—This company, the most important of its kind in Holland, has held its annual meeting at Utrecht. From the report of the directors it appears that results have been more favourable upon the whole than in 1890. The receipts from passenger traffic were £11,609, whilst luggage yielded £213, goods £2,613, and cattle £567. The net profit of £2,138 allowed of the distribution of a dividend of £1 13s. 4d. per share of £83 6s. 8d. each.

The Blitong Tin Company.—The Government has submitted a Bill to the States-General, embodying its contract with the board of the company. It urges its acceptance as the maximum obtainable under the present circumstances. If it be true that the Government has not been able to secure the 10 per cent. royalty which it at first insisted upon, and has had to be satisfied with the royalty of 5¼ per cent., now stipulated, it is equally true that the company is no longer able to deduct from the annual profit a first sum of £41,666 for dividend purposes. That amount has been reduced to £29,166, and, after deduction of the latter sum, the net profit becomes dividable between the Government and the company in equal moieties.

Dutch Phosphate Company.—The directors of this new undertaking have submitted a first report to the shareholders, which reads favourably. The company is in possession of phosphate mines in Canada and in Florida, covering together a superficial area of about 2,000 acres. The property in Florida is particularly described as very promising; 6,000 tons from that property have already been sold at remunerative prices. The working of the mines in Canada is shortly to commence.

The Gallicia Tin Company.—Some years ago the Dutch Gallicia Tin Mining Company was formed, with a capital of over £166,666, to work tin mines in Gallicia. The capital of this concern has just been "re-arranged" by special resolutions of the shareholders. The share capital has thereby been reduced to £150,000, in shares of £1 each. There are, moreover, five per cent. debentures to the amount of £100,000. Prospects are declared to be good, although no dividend is as yet forthcoming.

An Adventurous Survey.—Recent advices from Sumatra report the departure from Padang to Siak of an expedition, organised and led by the principal Government civil engineer, Mr. Yzerman, for a survey in connection with a railway to be constructed through Sumatra, from coast to coast. The expedition has numerous carriers, and is accompanied by scientists appointed to make special reports upon minerals, plants, and woods during a seventy days' ramble through regions that no European has as yet ever trod.

STOCKHOLM, 16th May, 1891.

Finnish Railway.—It has now been decided that an official examination shall be made with regard to the proposed railway between Uleaborg and Tornea, so that a Bill for the construction of this important railway may be introduced into the next Senate.

New Gunboat.—The Kockum Engineering Company, Malmö, has secured a contract from the Swedish Government for a new gunboat, the "Svensksund," which is to be built of the best Swedish steel. It is to have duplex direct-acting propeller engines, with a capacity of 440 i.h.p. At

Digitized by Google

the yard of the same firm was launched on the 9th inst. the new steamer "Rzfylke," built for the Stavanger Steamship Company, Norway, and intended for the tourist traffic.

THE ORNSKÖLDSVIK-MELLANSEL RAILWAY.—Parliament has voted £101,277 towards the construction of this important line,

THE HELSINGBORG SHIPYARD.—This shipyard is to be extended so that iron vessels also may be repaired there. This has been decided upon with the co-operation of the Helsan Engineering Company.

STATE TELEPHONES AND PRIVATE TELEPHONES.—The Swedish Government has sanctioned an arrangement between the State Telephone Administration and the large Stockholm General Telephone Company, in accordance with which the company has the right to carry new lines and to maintain the old lines within a radius of 70 kilometres in all directions from the main market place in Stockholm for a period of fifty years. After the expiry of this term the State Telephone Administration has the right to purchase the company's lines outside Stockholm at a valuation. If the State Telephones Administration should not avail themselves of this right, then the company is entitled to a prolongation of its concession subject to certain conditions. The Stockholm General Telephone Company has sold several of its provincial lines, and undertaken not to carry on telephone business in Sweden outside the radius of 70 kilometres from Stockholm.

CHRISTIANIA, 16TH MAY, 1891.

SALE OF COPPER MINES.—The copper mines at Riple, belonging to Mr. Corneliussen and others, have been sold to an English syndicate for experimental working. If the result proves satisfactory the mines will be finally transferred to the English syndicate at a very fair price.

NEW PAPER MANUFACTORY.—It has now been settled that the new industrial establishment at Borregaard shall also comprise paper mills.

THE BENTSE WORKS.—Messrs. H. & C. Bacho Wüg have sold their Bentse paper mills to a limited company under the style of "Akerselvens Papirfabriker." The price is £61,111.

THE NORWEGIAN MILK CONDENSING COMPANY.—This company, which was formed at Toten two years ago, with a share capital of £16,666, and in which King Oscar was a shareholder, is now ready for work. The capital has, however, proved insufficient, and a fresh issue of £11,111 has been deemed necessary.

THE BJÖRSHOLMS WORKS.—This establishment, founded lost year for the manufacture of buckets made from pressed wood pulp, also finds it necessary to increase its capital; the new issue is of preference shares, not exceeding £9,333.

EXPORT OF NORWEGIAN BOARDS TO PERSIA.—An increasing export of boards for fruit boxes is taking place from Norway to the Persian Gulf. The shipments used to be effected *viâ* London, but now Norwegian steamers go direct from Norwegian to Persian ports.

COPENHAGEN, 16TH MAY, 1891.

NARROW GAUGE RAILWAYS.—The numerous light railways proposed by Mr. Steinberg, to be built in various parts of Denmark, are attracting much attention. It is thought that these railways may in many places prove a considerable boon to fishing and to agriculture. It is proposed to carry one of these railways through the vast moors of Jutland. The cost will be very small.

DANISH BACON FACTORIES.—The question of an amalgamation of all the Danish bacon factories, co-operative as well as private, has been much discussed lately. The difficulties in the way have, however, proved too great, but now the question seems in a fair way of being arranged. At a meeting of delegates held on the 11th inst., Mr. C. F. Tietgen being in the chair, a basis was agreed upon, which will now be laid before the various factories for final acceptance. The style of the new business is to be "The Danish Bacon Factories." The capital will be divided into "debenture shares" and ordinary shares. The amount of the former is to be equal to the aggregate valuation of all the bacon factories with machinery, with an additional amount for the higher value of the I. D. Koopmann marks in the English market. The nominal amount of the ordinary shares is £222,222. Of this sum the private factories and the co-operative factories each obtain one-half as the value of working capital. The ordinary shares are distributed among the different factories in proportion to their output. The net profit is to be disposed of in the following manner: 4 per cent. on the debenture shares, then 4 per cent. on the ordinary shares; of the balance 25 per cent. are added to a reserve fund, and the remaining 75 per cent. are distributed among the ordinary shares.

NEW RAILWAY CARRIAGES.—The Danish State Railways have ordered some "bogie" carriages from the Skandia works at Rouders, which are intended to be used for the foreign express trains on the Sealand lines. These carriages are twice the size of ordinary railway carriages, and they rest upon two systems of bogies, each bogie being carried upon four wheels. A spring arrangement will further tend to reduce the shaking as much as possible. The new carriages will be divided into compartments, and will not be provided with a passage from end to end as is the case in Norway and Sweden. The compartment system is thought more convenient for the shorter Danish lines.

THE FAXE LIME WORKS.—The large Faxe Lime Company is improving its position owing to able management, and to arrangements made with other Danish and Swedish lime companies. The bricklayers' strike last summer and the long and severe winter diminished the sale, but the net profits for last year were £10,268, as compared with £9,286 in 1889. No dividend was, however, declared, but hopes were expressed that the shareholders would receive a dividend next year.

MADRID, 18TH MAY, 1891.

IMPORTANT AMALGAMATION OF RAILWAYS.—The Tarragona and Barcelona Railway has just been sold to the Southern Company of Spain under circumstances which show some rather sharp practice. The manager of the Tarragona Railway had made an agreement with the Northern Railway Company to sell them that line, which, with other concessions, was estimated to be worth £5,000,000, subject to the approval of the shareholders. At a meeting of the shareholders on the 10th inst. it was proposed to discontinue negotiations with the Northern Company, and it was decided to sell the line to the Southern Company, a secret arrangement having already been made with that object. The shares of the Northern system, and of the Banco Hispano-Colonial, which is connected with this railway, suffered a heavy fall in consequence of this announcement, as it was thought that the previous arrangement was already concluded. Señor Planas, the Chairman of the Southern Company, had in fact already made arrangements with the Rothschilds to obtain funds for the purchase of the Tarragona line, and thus got the better of the Marquis de Comillas and Señor Sosotongo, a group of financiers connected with the Banco Hispano-Colonial. It is thought that the action of Señor Planas was influenced by the fact that he had been similarly deceived by this bank a few months ago, when he tried to buy the Almansa and Valencia railway. The financiers connected with the Northern line will thus lose their control of the Barcelona financial market, which will now be assumed by the Rothschilds. The Rothschilds now have the control of seven-tenths of the whole traffic of the country, and would be able to inflict great injury on the Northern system. Their arrangement for the purchase of the Tarragona line includes an advance of £1,250,000 at 4 per cent. to complete the line which is being made from Reus to Saragossa. There is also an engagement to make a railway from Valladolid to Ariza within three years, and to connect the system with Almanza. This last clause may not, however, be carried out, as the lines from Almanza to Valencia and Tarragona will certainly be sold to them. The Rothschilds will probably obtain the concession of the line from Calatayud to Feruel and Castellon, and may possibly make an amalgamation with the Gran Central Español. The Banco Hispano-Colonial had devised a scheme for freeing the Spanish railways from foreign control, but this scheme is now at an end. The tariffs on many of the railways are very high, and little attempt is made to develop the traffic. The Northern system is well managed, though the traffic is not so susceptible of development as that of the Southern and Mediterranean system. It may possibly be the case that there is a scheme in hand relating to the remaining principal lines with a view to the introduction of the zone tariff system.

UNION OF COAL MINE OWNERS.—A large number of coal mine owners have formed an association with the title of the "Union Hullera," in order to protect their interests. Their chief aim is to obtain an increase of the duty on coal, which is now only 1s. per ton. Such means of increasing the price of coal seem unjustifiable, as the mine owners are not able to keep pace with the actual demand. This is shown by the fact that the imports of coal during the first four months of this year are in excess of those of the previous year by 25 per cent.

ROME, 18TH MAY, 1891.

AN ELEVATED ELECTRIC RAILWAY.—The highest elevated railroad in the world is about to be built in Naples. It is intended to connect the central part of Naples with the Corso Vittorio Emanuele. It is designed by Mr. Adolfo Aveno, civil engineer, and the estimated expense will be about £200,000. The road will be suspended from towers 100 metres high, in which will be elevators to carry passengers to the station. The road will be operated by electricity, generated by the force of the waterfall of the River Serreno.

THE WOOLLEN INDUSTRY.—Recently published statistics show that there are about 300,000 spindles and 100,000 looms employed in the Italian woollen industry. Seven-tenths of the latter are hand looms. About 30,000 operatives are employed, principally in Vicentino, in the Biella district, and in the Terra del Lavoro.

ACCIDENTS IN MINES.—The total number of accidents in the mines of the whole Kingdom during 1889 amounted to 196, with 68 deaths and 171 injured, whilst in 1888 there were 301 accidents, with 87 deaths and 286 injured persons. If the larger production of 1889 is taken into consideration it appears that a remarkable improvement has been realised as regards the safety of the mines. In fact, for every 1,000 persons we have the following figures:—

	1888.		1889.
Accidents	6·13	...	4·00
Deaths	1·74	...	1·39
Cases of injury	5·82	...	3·48

Comparing the value of the production with the number of deaths, we find one death for an output of the value of £24,080 in 1888, and one for an output of the value of £31,480 in 1889. In 1887 there was one death for every 720 persons employed, whilst in Great Britain in the year 1889 (see *Industries*, Vol. X., page 350) there was one death for every 538 persons employed.

UTILISATION OF WATER POWER.—An important work has recently been completed for supplying the power for an electric tramway between Pazzala and Lugano. The power is obtained from a waterfall, the water being conveyed to the generating station in iron pipes, where two turbines of 300 h.p. each drive a 1,500-light dynamo and a 60 h.p. generator.

BRITISH COAL.—The amount of British coal imported into Italy in 1890 was as much as 1,493,600 tons, against 1,307,600 tons in 1889 and 1,279,400 tons in 1888. Of the above total import in 1890, 749,000 tons were from Cardiff, 574,700 tons from Newcastle, and the rest was Scotch and North English coal from Liverpool and Hartlepool.

NEW YORK, 9TH MAY, 1891.

RAILROADS.—The Chicago, Kansas, and Nebraska Railroad was sold at Topeka, Kansas, to satisfy a mortgage of £5,200,000 against the company in favour of the United States Trust Company, of New York. The railroad was bought by an agent of the latter company for £5,066,400, its appraised value.—Arrangements are being completed for building the long-contemplated railroad from Dewitt, Neb., to Omaha and Lincoln, making a short line to the latter cities. It is stated that the Burlington and Mississippi River Railroad is supporting the project.—Contracts have been awarded for the construction of an extension of the Reading Railroad from Bound Brook to Arthur Kill, and the contractors will begin work at once. It is stated that the railway, which is to cost £300,000, will be in operation within one year. A tunnel is to be built under the Detroit River from Detroit to Windsor on the Canadian shore. It is to be 8,000ft. long, and will have cuttings of 1,000ft. at each end. There will be two railroad tracks in the tunnel.

PHILADELPHIA, 8TH MAY, 1891.

THE CONNELSVILLE STRIKE.—The Frick and McClure companies are steadily increasing their working forces. Seven thousand workmen, including a number of negroes and Italians, are to be imported from the East this week. A coke famine is threatened in Chicago owing to the strike in the Connelsville district. The Illinois Steel Company and the Calumet Steel and Iron Company have been compelled to abandon their furnaces for want of fuel, and more than 1,500 men have been thrown out of work.

LARGE "OTTO" GAS ENGINES.—During the last year or two a variety of changes in the "Otto" gas engine have been effected by Messrs. Schleicher, Schumm, & Co., of Philadelphia, who are the sole builders of this type of engine in America. Besides the numerous changes in the details of construction of this engine, the range of power and speed have been extended to such a degree that it has become a formidable rival to the most economical steam engine. The smallest engine of this type is ¼ h.p. (vertical), while the largest is 100 h.p. Only one engine of this size has as yet been put into successful operation. It is at Rockfield, Conn. It is driven by means of water gas, and furnishes the total power for an electric light installation. Three such engines have been ordered, and are now in course of construction. Some of the most important points in the construction of the engine have been materially changed. The 100 h.p. engine is horizontal, with two cylinders placed one above the other. The connecting rod of the top cylinder is hinged to that of the bottom in such a way that the two together actuate a single crank. The ignition of the gas in this engine is no longer affected by a flame, but an incandescent metallic tube is now provided for that purpose, which, although of very short life, is more satisfactory and less expensive than the old method. The slide valve, which was the source of much trouble in the old type, has, in this engine, been replaced by poppit valves. As a result of recent trials of this engine in connection with a gas producer it is claimed by the company that the engine developed 1 h.p. per hour for each pound of carbon consumed, which, if correct, is an exceedingly low figure. It is proposed by the Department of Mechanical Engineering of the University of Pennsylvania to make an official test of the performance of this engine, the results of which are looked forward to with some interest. The company has recently applied the "Otto" principle to the construction of gasoline engines of small powers. In these the ignition of the mixture is effected by an electric spark produced by a battery of Edison-Lelande cells in connection with a small spark coil. This method which has proved cheap and reliable, has been applied to some of the regular type of "Otto" engines, and has in every case given satisfactory results.

NEW BRANCH ON THE READING RAILROAD.—The new branch of the Philadelphia and Reading Railroad, known as the Philadelphia, Harrisburg, and Pittsburg Railroad, was recently completed. This railroad crosses the Susquehanna River by a very large bridge at Harrisburg; it connects at Shippensburg with the Maryland and Western and Baltimore and Ohio Railroads, and branches off to Pittsburg and the coke regions. This railroad will be of great value in the Schuylkill, Lehigh, and Lebanon valleys, where the industries use coke extensively, and it is expected that a large freight business will be done.

THE ROYAL NAVAL EXHIBITION.

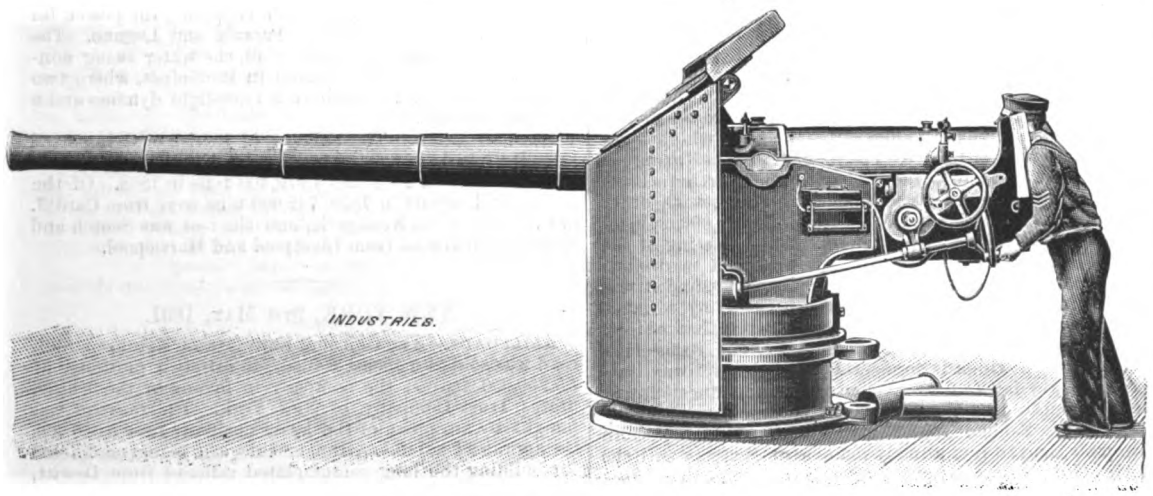

Fig. 1.—The 4·7in. Quick-firing Gun.

THE ROYAL NAVAL EXHIBITION.

SIR W. G. ARMSTRONG, MITCHELL, & CO.'S EXHIBITS.

Continuing our description of the exhibits from the Elswick works of Sir W. G. Armstrong, Mitchell, & Co., we illustrate in Fig. 2, on page 492, H.M.S. "Victoria" in the act of firing her guns. Allusion has already been made to the model of this vessel, specially constructed for this Exhibition, which, along with the photograph we reproduce, should enable visitors to form an idea of the great advances in the construction and equipment of war vessels during recent years. The model of the "Victoria" represents the vessel with her torpedo nets down (the nets, carefully finished, were made by Messrs. Bullivant & Co.) and generally ready for action, as would be the case if gun or torpedo attack were anticipated.

A comparison of the "Victory" with the "Victoria" will further accentuate the development that has taken place in the dimensions, displacement, armament and otherwise of "first-class" war vessels. The "Victory" was a three-decker, 186ft. in length, 52ft. beam, and 3,500 tons displacement, the armament, 102 guns, consisting of thirty 42 and 32-pounders, thirty 24-pounders, forty 12-pounders, and two 68-pounder carronades, the heaviest of the guns being the 42-pounder, the largest charge 10lb. of powder, and the heaviest shot 68lb. The "Victoria" has a length of 340ft., 70ft. beam, and 10,500 tons displacement, the armament consisting of two 16¼in. 110-ton guns, one 10in. 30-ton gun, twelve 6in. 5-ton guns, twelve 6-pounder and nine 3-pounder quick-firing guns, two machine guns, and six torpedo guns. The largest charge is nearly 1,000lb., or 100 times greater than in the "Victory" and the largest shot 1,800lb., or more than twenty-six times heavier than in Nelson's flagship. The weight of metal discharged from the broadside of the "Victory" was 1,150lb., from that of the "Victoria" it is 4,750lb.; but as this latter contrast does not take into account the energy of the broadside, the power of each of these vessels is better indicated by the quantity of powder expended in a broadside fire, which in the "Victory" was only 355lb. of powder, as against 3,120lb. in the "Victoria." Manual power for working the guns was solely employed in the old "first raters," and the guns, with few exceptions, were "mere blocks of cast iron," except "the formation of the bore and the drilling of the vent," and the gun carriages were very primitive. In the "Victoria," air-compressing, hydraulic, and steam power is brought into requisition, and whereas the arrangements in the "Victory" were of the simplest character, in addition to the main engines used in propelling the "Victoria" there are in connection with them no less than twenty-four auxiliary steam engines—viz., two starting, two reversing, eight feed, eight fan, four forced draught—and four circulating water engines. Besides, there are thirty steam independent engines—viz., six fan and bilge engines, two auxiliary circulating engines, four fan engines for ventilating purposes, two fresh-water pumping engines, two evaporative fuel engines, one workshop, one capstan and five electric-light engines, four air-compressing and three pumping engines for hydraulic purposes. The "Victoria" has also thirty-two hydraulic engines, including two for actuating the rudder, four for ash hoists, two boat engines, four ammunition lifts, two turret-turning engines, one topping winch, two transporting and lifting engines, two hydraulic bollards, and fourteen other engines for performing operations necessary in working the heavy guns. This makes a total of eighty-eight engines, and is exclusive of the machinery in the torpedo and other steam boats, and of the locomotive engines in the torpedoes.

There are, besides the large model of the "Victoria," several others of almost equal interest exhibited by Sir W. G. Armstrong, Mitchell, & Co., Ld. One of these represents, on the scale of 20ft. to an inch, the Elswick Shipbuilding Yard, which is capable of containing nine vessels on the stocks at one time, besides a number completing in the River Tyne. The enormous shear legs, designed to lift over 100 tons, are shown in the act of lowering a boiler into a cruiser. Another model represents the piling under the berths specially designed for armour-clads, of which there are two at the east end of the yard.

The "Esmeralda," which may be fairly styled the "pioneer" modern protected cruiser, is represented by a model on the usual scale of ¼in. equals 1ft. This vessel was built at the Walker shipyard in 1882-3 from the designs of Mr. George Rendel, and is 270ft. in length, 42ft. beam, displacement about 3,000 tons, on a draught of water slightly exceeding 18ft., when fully stored, armed, and equipped for sea. Some years previously smaller vessels of a similar type were built for China and Chili, but the closeness of their bow and stern chasers to the water made them practically useless, even in moderately heavy weather, and their vital parts were very incompletely protected. In the "Esmeralda" these defects were remedied. This vessel has an arched protective steel deck, beneath which are the engines, boilers, &c., while above are the coal bunkers. The buoyancy and stability are further protected by means of cork-filled cellular compartments extending nearly round the vessel. The armament of this vessel consists of two 10in. 25-ton breechloaders, two 6in. 4-ton guns, two 6-pounder quick-firing guns, five 37mm. Hotchkiss guns, and two Gardner guns. The propelling machinery consists of two sets of horizontal compound engines, driving twin screws, of 5,500 i.h.p., giving a speed of 18·28 knots per hour on the measured mile trial.

The "Giovanni Bausan," for the Italian Government, was constructed of practically the same design, but in the "Haniwa-Kan" and "Takachiho-Kan," of which Japanese cruisers a full model is exhibited, many improvements were introduced. These vessels are about 700 tons greater displacement than the "Esmeralda," and are provided with inner bottoms for a large portion of their length. Their protective decks extend the whole length and slope upwards from below the water-line at the side to a few inches above that level at the middle line, the sloping sides being 3in. and the centre portion of the decks 2in. thick. Greater protection is thus given to the buoyancy and stability, and, while the vessels have the same armament as the "Esmeralda," their increased size allowed the engines to be made of greater power to obtain a higher speed—viz., 18¾ knots. These vessels were the first designed by Mr. W. H. White after he joined the Elswick establishment. In the "Dogali," built for the Italian Government, Mr. White succeeded in obtaining a speed of 19½ knots on a displacement of 2,050 tons, but the largest guns on this vessel were only 6in. breechloaders. About the same time, the Austro-Hungarian cruisers "Panther" and "Leopard" were completed—vessels of a smaller type, but of high speed—viz., 18½ knots. The next model to attract attention is, however, that of the Chinese protected cruisers, "Cheh-Yuen" and "Ching-Yuen," vessels still more heavily armed and better protected, having three 8in. breech-loading guns, two 6in. guns, and 24 quick-firing guns of various sizes, besides four torpedo tubes. The protective deck on the slopes is 4in. and at the centre line 2in. thick. Their length is 250ft.; breadth, 38ft.; draught of water, 15ft.; and displacement, 2,300 tons. With forced draught the engines exerted 6,892 h.p., with which a speed of 18·5 knots was realised.

The Roumanian cruiser "Elizabeta's" model is near the last mentioned. As this vessel is a training ship, a much greater spread of canvas than is usual in this type of vessel was provided, but otherwise there is no specially noteworthy feature. Of greater interest is the Italian cruiser "Piemonte," in which a further advance was made in speed and protection. Having previously illustrated and described this vessel in connection with the Paris Exhibition, at which the model exhibited obtained a gold medal (see *Industries*, Vol. VII., page 185), a brief reference must now suffice. The vessel has 2,500 tons displacement, and attained a speed of 20½ knots with natural and 22·3 knots with forced draught. At the time of her completion—1888—the "Piemonte" was the only vessel armed with the new quick-firing guns, which permitted of twice the weight of shot and shell being fired against an adversary, even though the latter were five and six times her size, in a given time. This vessel was designed by Mr. Philip Watts, the present chief constructor at Elswick, but has since been eclipsed by the Argentine cruiser "25 de Mayo," now about ready to sail from the River Tyne, of which a full and carefully finished model is also exhibited.

There are other two models of war vessels very recently constructed at Elswick exhibited. One of these represents the three protected cruisers, "Katoomba," "Mildura," and "Wallaroo," for the Australian Colonies. These vessels are 265ft. in length, 41ft. beam, 15ft. 6in. draught of water, and 2,600 tons displacement; but owing to their size have not the powerful armament nor great protection obtained in the "25 de Mayo." The other model represents the torpedo-boat destroyers "Boomerang" and "Karakatta," of the Australian Colonies, and the "Plassy" and "Assaye," of the Indian Government, of which the two latter have not yet left the River Tyne.

There yet remains for mention a model of a large twin-screw mail and passenger steamship, which is very completely finished, and shows signs of considerable care in designing, most noteworthy being the free use of hydraulic power for the loading and discharging of cargo, and the model of the crane vessel "Atlas," designed and built by Sir W. G. Armstrong, Mitchell, & Co. for the Mersey Dock and Harbour Board.

The ordnance exhibits now demand some attention, and prominent amongst these are the quick-firing guns, the latest product of the Elswick artillery department. These guns differ from "Nordenfelt," "Gardner," and "Gatling" guns in being loaded by hand, in having only one barrel, and generally in being larger in size. The "quick-firing" gun differs from an ordinary gun by having special breech mechanism, and particularly by the use of cartridge cases, which are generally made of brass or gun-metal, composed of two or more pieces screwed or riveted together, or solid-drawn out of one piece. One of these cartridge cases constructed in the latter manner, which has been fired twenty times in a 4·7in. quick-firing gun, is exhibited to show how successfully they are constructed. After each time of firing these cartridge cases are re-formed, for which purpose special tools are provided.

The first quick-firing guns were made to fire 3lb. and 6lb. projectiles at the rate of twenty to thirty per minute under favourable conditions. Since then guns of this type have been constructed to discharge projectiles of 10lb., 12lb., 25lb., 30lb., 45lb., 70lb., and 100lb. The 12c.m. (4·7in.) quick-firing gun has, however, been so far the most largely adopted of the larger sizes, and above and on page 492 will be found illustrations, Fig. 1 showing the external appearance, and Figs. 3, 4, and 5 sectional and end views of this gun as now made. Originally introduced as a 30-pounder, it was submitted to the Admiralty (in 1886), and most exhaustively tried at Portsmouth. These trials resulted in some slight modifications to the gun, which was finally adopted by the Navy as a 45-pounder. Ever since the Elswick Company have found it difficult to manufacture this weapon with sufficient rapidity to cope with the demand, and there still appears every probability of the "quick-firing" type being more extensively adopted. Interesting trials have been carried out by the Admiralty, in order to compare the rates of firing of the new 4·7in. quick-firing gun and the 5in. breech-loading service gun. Both these weapons were mounted in gunboats, and fired under precisely similar conditions, the result being that the 4·7in. gun fired 10 rounds in 47 seconds, and the 5in. gun took 5 minutes 7 seconds to

Digitized by Google

fire an equal number. Evidently it is only a question of time and money for the complete superseding of the ordinary service gun by the rapid firer. Besides having the advantage of firing six times as often, the latter has the further advantage that between each discharge but a slight alteration in aim is required.

Noteworthy amongst many improvements, introduced to ensure rapid loading and firing, is the Elswick breech screw. It is on the principle of the interrupted screw, but is made of a coned instead of a cylindrical shape. This arrangement secures two advantages, viz., firstly, the action of opening and closing the breech is much simplified, as the breech screw need not be withdrawn before hinging away; and, secondly, the coned shape of the breech screw enables it to take hold, not only of the inner surface of the metal of the breech hoop or jacket, but also distributes the engagement, and, therefore, the strain and support, over a much larger surface. The breech screw is further arranged so that the threads of the smaller end of the cone correspond longitudinally with the interrupted spaces of the larger end, and *vice versâ*, so that the strain and support are also distributed throughout the entire circumference of the breech screw, instead of, as formerly, half the circumference being lost by the interrupted spaces.

Electricity is used as the means of firing these guns with advantage, as electric primers can be kept in the loaded cartridge cases without the slightest danger. An explosion would be so serious that percussion primers would never be tolerated in the cartridge cases, except just before firing, however unlikely accidental explosion might be considered. Further, the use of electricity facilitates arrangements to secure the guns being in proper firing position when fired—especially necessary, seeing that the rapidity of firing is very liable to lead the gunners to omit some of the routine of their work. To obviate failure the electric light is always supplied in duplicate, and sometimes even a third current is provided, and percussion firing can also as a last resort be substituted with barely a moment's pause.

An ingenious electric sounder has been devised to assist in providing against miss-fires, and can be seen in action in the Exhibition. It commences to ring, if everything is in order, directly the gun is loaded and in the firing position. By its means all the primers can be tested before actually required for firing, and further it has the merit of being free from complication. Considerable attention has naturally been given to providing a suitable mounting for these guns. Instead of being fitted with trunnions they are placed in cradles, keys being provided on the guns, which, working in keyways in the cradle, prevent the gun from turning. The breech of the gun is fitted with a horn, which is connected with a piston rod working in the recoil press cylinder under the cradle. Two steel rods are also attached to the horn on the gun, and, passing each side of the recoil cylinder, are connected with a spiral spring which causes the gun to return to the firing position after absorbing the recoil energy. On the cradle are trunnions which fit into bearings in the sides of the carriage. The latter are cast-steel, and are bolted to the upper roller path and to the 3in. vertical shield which forms the front part of the mounting. The upper roller path is stamped into form by hydraulic pressure. It runs on twenty-four rollers, provided with flanges on the interior edges, and kept in place by a circular ring, each roller working on to an axis bolted on to the ring. Thus the resistance offered by friction is minimised, and the training of the gun we illustrate can be effected with ease by a push, although gearing is provided. Elevation is obtained by a hand-wheel geared into the elevating arc fitted to the cradle, placed so that it can be used with the left hand while the eye is on the sights, the right hand on the firing pistol, and the left shoulder pressed against the shoulder piece, so that one man can train, elevate, fire, and sight the gun simultaneously.

SHIPBUILDING NOTES.

On the 1st inst. the large steel screw steamer "Lincolnshire," carrying 4,000 tons, which has been built by Messrs. Wm. Gray & Co., Limited, and engined by the Central Engine Works, to the order of Messrs. Money, Wigram, & Sons, Limited, London, went on her trial trip. She is fitted with engines of 23in., 36½in., and 62in. diameter of cylinders, and a stroke of 39in. A special feature is a double-funnel. The vessel made a speed of 12¼ knots per hour on the whole distance, the engines being run at 91 revolutions per minute.

On the 2nd inst. the yacht "Irene," built by Messrs. A. & J. Inglis for Prince Henry of Germany, was launched on the Clyde. The "Irene" has been built to the designs of Mr. G. L. Watson. The Emperor of Germany and his brother are now both owners of Clyde-built yachts designed by Mr. Watson, the Emperor having recently bought the "Thistle" from the syndicate under whose auspices the vessel was built.

Notices of Meetings.

THIS WEEK.

Royal Institution.—Friday, May 22nd, at 9 p.m. Lecture on "The Molecular Process in Magnetic Induction," by Professor J. A. Ewing, M.A., F.R.S. Saturday, May 23rd, at 3 p.m. Lecture III., on "The Artificial Production of Cold," by Mr. H. G. Harris, M.Inst.C.E.

Physical Society.—Friday, May 22nd, at 5 p.m. Papers to be read: "Dr. Schobben's Form of Lantern-Stereoscope," by Mr. C. J. Woodward, B.Sc.; "A Simple Steam Engine Indicator Accurate at any Speed," by Professor J. Perry, F.R.S.; "Mr. Blakesley's Method of Measuring Power in Transformers," by Professor J. Perry, F.R.S.; and "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power," by Professor W. E. Ayrton, F.R.S., and Mr. W. E. Sumpner, D.Sc.

NEXT WEEK.

Institution of Civil Engineers.—Tuesday, May 26th, at 8 p.m. Annual general meeting.

The Federated Institution of Mining Engineers.—Thursday, the 28th inst., at 12 noon, and Friday the 29th, at 10 a.m. Papers to be read: "Notes on Coal Dust," by Mr. Henry Hall (H.M. Inspector of Mines), Rainhill, Prescot; "On Locked Coil Wire Ropes," by Mr. Wm. Foggin, Durham; "The Economical Use of Steam in Colliery Engines, with Results of Experiments," by Mr. John McLaren, Leeds; "The Coal Fields of New South Wales," by Mr. Geo. Blake Walker, Barnsley; "The Coal Fields of Australasia," by Mr. S. Herbert Cox, London; "The Detection of Fire-damp," by Professor F. Clowes, Nottingham, and Mr. James Ashworth, Stanley, Derby; "Reports as to the Fumes Produced by the Explosion of Roburite, Tonite, and Gunpowder"—I. Chemical Report, by Dr. P. Phillips Bedson, Newcastle-upon-Tyne. II. Medical Report, by Dr. David Drummond and Dr. George H. Hume. III. Joint Statement of Conclusions and Recommendations, by Dr. P. Phillips Bedson, Dr. David Drummond, and Dr. George H. Hume. IV. Appendix to Chemical Report. "An Electrical Safety Apparatus for Cages," by Mr. John Yates, London.

Society of Arts.—Thursday, May 28th, at 4.30 p.m. Paper to be read: "The Study of Indian History," by Mr. Charles Lewis Tupper, B.A., Bengal C.S. (Punjab).

PRICES CURRENT, 20th May, 1891.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: Quiet, with small business during the holidays. The visible supply of copper decreased about 1,000 tons during the first fortnight of May. The Chili bar market has been strong during the past week, and values have steadily improved. Current quotations are £51 17s. 6d. to £52 5s. cash, with firm market. Manufactured, £63 10s. to £64, "strong."

Tin: Firmer, values of foreign having advanced considerably during the past week.

Lead: Quiet, with small inquiry.

Spelter is much firmer, the Belgian strikes and the workmen's action on the Continent having materially affected the output.

We have received the first number of a new American monthly journal entitled *Engineering*. This journal, which is issued by the Engineering Magazine Company, 124, World Buildings, New York, is well illustrated, but is not got up in the style usually adopted by the technical press, but takes more the form of a popular monthly magazine, and contains some interesting technical reading. Looking down the list of contents we find the following:—"Keeping the Mississippi within her Banks," "Gold Mining in Peru by the Incas," "The Second Summers of Village Communities," "The Mechanical Display at the World's Fair," "The Greatest Bridge in the World," "A Chat with Europe by Telephone," "Engine Room Chat," along with articles upon civil engineering, architecture, electricity, mining and metallurgy, and mechanics. We notice that the second number is entitled the *Engineering Magazine*. This, we think, is an advantage, and will prevent its being confounded with our English contemporary *Engineering*. We wish our contemporary every success.

HOME INDUSTRIES.

LONDON, 21st May, 1891.

THE MONEY MARKET.—The influx of gold which has been attracted to this country by the advance in the Bank Rate to 5 per cent. has allayed the worst fears of those who were looking for a prolonged period of monetary stringency. Of course with the official rate at that point the situation cannot be considered easy, but satisfaction is felt at the continuous reinforcement of the Bank reserve and the virtual cessation of the draft on the slender stock of gold held in London. The amelioration of the position of the Paris Bourse and of the condition of affairs at Lisbon also tends to reassure the money and stock markets. The latter have shown a distinct tendency to improve during the week. All the investment stocks have risen in view of the better tone of the money market, and foreign securities have strengthened in response to the more satisfactory news from Paris. But Americans have been less ready to recover, the heavy exports of gold from New York continuing to depress the market there, and counteract the influence of the local conditions of the railroads, which are by common consent admitted to justify a substantial advance in prices. The lesser departments of the Stock Exchange have been featureless and business has been on a restricted scale.

THE INSTITUTE OF MARINE ENGINEERS.—A meeting of this Institute was held on the 12th inst., presided over by Mr. F. W. Wymer, Vice-President, when Mr. Macfarlane Gray gave a popular lecture on "Logarithms," at the special request of the Council. The subject was treated mathematically and historically. The lecturer succeeded in riveting the attention of his audience for an hour and a half, and presented his mathematical investigations in a most attractive form. Logarithms, he said, had been to science what steam had been to commerce, and Scotland's greatest glory is not commemorated by any one of the monuments in Princes Street Gardens, but by the brass plate in the porch of St. Cuthbert's Church, which tells that John Napier, the Laird of Merchiston, the inventor of logarithms, is buried there. In the remarks which followed, Messrs. Hawthorn, Williams, and the Chairman took part. A vote of thanks to the author of the paper and the Chairman was passed. At the next meeting of the Institute, on the 29th inst., the subject will be "The Metacentre," popularly explained by Mr. Macfarlane Gray.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on the 20th inst., Mr. Baldwin Latham, M.Inst.C.E., F.G.S., President, in the chair, when the following papers were read:—(1) "On the Vertical Circulation of the Atmosphere in Relation to the Formation of Storms," by Mr. W. H. Dines, B.A.: After giving an outline of the circulation of the atmosphere, the author referred to the two theories which have been suggested to account for the formation of storms—viz. (A) The convection theory, which is that the central air rises in consequence of its greater relative warmth, this warmth being produced by the latent heat set free by condensation; and (B) the theory that the storms are circular eddies produced by the general motion of the atmosphere as a whole, just as small water eddies are formed in a flowing stream of water. The author was of opinion that the convection theory was the more probable of the two, but thought more information about the temperature of the upper air was needed. (2) "On Brocken Spectres in a London Fog," by Mr. A. W. Clayden, M.A.: During the dense fogs in February last the author made a number of experiments with the view of raising his own "spectre." This he ultimately succeeded in accomplishing by placing a steady lime-light a few feet behind his head, when his shadow was projected on the fog. He made careful measurements of the size and distance of the spectre, and also succeeded in taking photographs of the phenomenon. (3) "An Account of the 'Leste,' or Hot Wind of Madeira," by Dr. H. Coupland Taylor: The "leste," the author stated, is a very dry and parching wind, sometimes very hot, blowing over the island from the E.N.E. or E.S.E., and corresponds to the sirocco of Algeria, or the hot north winds from the deserts of the interior experienced in Southern Australia. During its prevalence a thin haze extends over the land, and gradually thickens out at sea until the horizon is completely hidden. It occurs most frequently during July, August, and September, and usually lasts for about three days. Mr. Shelford Bidwell, M.A., F.R.S., exhibited an experiment showing the effect of an electrical discharge upon the condensation of steam. The shadow of a small jet of steam cast upon a white wall is, under ordinary conditions, of feeble intensity and of a neutral tint. But if the steam is electrified, the density of the shadow is at once greatly increased, and it assumes a peculiar orange-brown hue. The electrical discharge appears to promote coalescence of the exceedingly minute particles of water contained in the jet, thus forming drops large enough to obstruct the more refrangible rays of light. It is suggested that this experiment may help to explain the intense darkness, often tempered by a lurid yellow glow, which is characteristic of thunderclouds.

THE LATE CAPTAIN F. P. WARREN, R.N.—It is with regret we have to announce the death of this well-known inventor, who some years ago, after a long career of service in the navy, retired into private life, but only to begin a new career as one of the most prolific of inventors. The patents which have been taken out by him cover almost the entire field of industry, and include a new form of lifeboat and lubricants for engines.

THE CITY AND GUILDS OF LONDON INSTITUTE.—A conversazione was held by the students of this Institution on the 15th inst. at the Finsbury Technical College. Professor S. P. Thompson, D.Sc., delivered a lecture, entitled "Electricity in Motion," and several engineering, electrical, and chemical firms lent apparatus for exhibition.

RAILWAYS.—The gross receipts of the twenty-three principal railways of the United Kingdom for the week ending May 10th amounted, on 16,245 miles, to £1,367,942, as against 16,159¼ miles and £1,351,006 for the corresponding period in 1890, an increase of 85¼ miles, or 0·5 per cent., and an increase of £16,936, or 1·2 per cent.

COMPETITIVE LIFEBOAT TRIALS.—The committee of the Royal National Lifeboat Institution have, we understand, decided to conduct a series of competitive lifeboat trials at Lowestoft next autumn, and invite inventors and others to enter boats for the competitions, under certain regulations and conditions, which can be obtained from the secretary of the Institution at 14, John Street, Adelphi. Intending competitors must give notice on or before June 30th next.

SOUTHWARK AND VAUXHALL WATER COMPANY.—A report has recently been drawn up by the Local Government Board with reference to the Southwark and Vauxhall Water Company's Bill for the creation of £300,000 of debenture stock. It is stated in the report that, though the number of houses supplied has risen from 90,535 in 1880 to 111,155 in 1889, and the estimated population from 672,677 to 825,886, the average daily supply has fallen from 23,985,827 gallons to 23,591,919 gallons during that period. It is suggested by the Board that the Select Committee of the House of Commons now inquiring into the London Water Bill should require the company to give particulars of the storage and subsidence reservoirs, and also of the projected new filter beds.

MANCHESTER, 21st May, 1891.

THE FIFTY-THREE HOURS QUESTION.—Following upon the successful agitation in Manchester for a reduction of the weekly hours in the engineering trades to fifty-three, and the movement for higher wages in Oldham, a circular has been issued to the Bolton employers, asking for a like reduction of hours. The annual report of the Machine Workers' Association also refers to this subject, and expresses a hope that the concession will shortly be made to affect the members of this association also. There is little doubt that uniformity in this matter is highly desired by the Manchester employers, who are already handicapped by the lower wages paid in the districts outside Manchester.

THE RATING OF MACHINERY.—At a conference, held in Manchester on the 15th inst., of representatives of various assessment committees throughout Lancashire, it was complained that the proposed Bill to exempt machinery from rating would add to the confusion already existing. It was urged by the Committee that what was really desired was a clear definition of the machinery liable to rating and that exempt, and that a clear gain would accrue from this, even if the liability to assessment was removed from certain classes of machinery. It was proposed that the machines which are fixed to buildings merely for the purpose of steadying them should be exempt, as well as all machinery used for producing or communicating motive power. It is difficult to see how any machinery used in ordinary manufactures could be rated under this proposed clause, except under a proviso including machinery requiring special adaptation of the buildings.

PHOTOGRAPHY OF COLOURS.—An exhibition of photographs of various coloured objects was given at a recent meeting of the Manchester Photographic Society. The photos were taken by a system invented by Mr. A. W. Scott, of Weston-super-Mare, who proceeds upon the theory that there are four primary colours, green, red, blue, and violet. He accordingly takes four distinct pictures simultaneously by means of four lenses, in front of which respectively is a screen of one of the four colours named. The negatives are developed in the ordinary manner, and in throwing the pictures on to a screen four lenses are again used having a common focus, each of the pictures being projected through a screen of the same colour as that originally used. The result is that a picture is produced which includes the colours of the original.

PAPER WORKERS' HOURS.—A conference of workers in paper mills was recently held in Manchester at which the question of working hours was considered. It was stated that the hours in Lancashire were very long, and that a good deal of Sunday work existed. It was resolved to insist upon the cessation of work on Saturday at two o'clock, and to refuse to work longer hours after the first Saturday in July. About 15,000 people are affected.

DAIRY WORK IN LANCASHIRE.—The Council of the Harris Institute in Preston have offered to the Lancashire County Council to erect a permanent dairy school where that class of work should be taught. They also propose to appoint a professor of agricultural chemistry, who would have at his disposal the extensive chemical laboratory already existing, and who would analyse samples of artificial manures for the farmers of the county. A migratory school is also proposed to be sent out to any district where thirty-two pupils are guaranteed.

LANCASHIRE AND THE BRAZILIAN TRADE.—The Blackburn Chamber of Commerce has called attention to the recent treaty between the United States and Brazil, which provides for the admission of many varieties of goods at duties about 25 per cent. less than those charged on British goods. They point out that out of £6,232,316 value of goods imported into Brazil, £2,500,274 represented the value of cotton goods. They ask for diplomatic action to secure a new treaty, and Lord Salisbury has promised attention to the subject.

THE LINEN AND JUTE TRADES.—There is not much doing in any department just now. Most of the houses have been closed during a portion of the week, and there was very little business passing even on Tuesday. As far as prices are concerned there is a steady feeling all round, and buyers are paying higher rates for bleached goods. The advance, however, is not considered sufficiently great in proportion to the increased cost of yarns, and manufacturers will make a special effort to get still better terms from merchants. Jute goods are steady, and prices of Hessians, although not quotably higher, are very firm, buyers finding it difficult to get in on their own terms. Yarns do not sell extensively here, but for such goods as offer a stiff rate is insisted on. Quotations have advanced all along the line during the past few months. Purchases of cloth on American account are maintained at a satisfactory level, the buyers now in the market having operated freely. For South America, however, there is very little doing, and the outlook does not improve.

GLASGOW, 21st May, 1891.

GENERAL.—So far as commercial matters are concerned the present week has been a broken one. The Whit week holidays have for two days closed the Stock Exchange and the banks, and produced a general holiday feeling, though as usual this has only been fully felt in commercial circles, the imminent approach of the midsummer holidays preventing its extension to industry. The pig iron warrant market has been closed on both days, so that there have been only two days' business in the Iron Ring this week. The state of the market is peculiarly perplexing. Trade is very dull, the amount of iron in course of withdrawal from stock is trifling, and production is increasing. Yet prices are going up, while during the depletion of the stocks and fairly brisk trade prices fell persistently. The cause of this apparent anomaly is probably temporary, and is no doubt due entirely to the manipulation of the market by speculators in Glasgow and London. An astute writer in a local weekly ascribes the movements to a preponderance in the strength of the English "bulls" over the Scottish "bears." It would appear as though the Scottish sellers had immensely oversold, and the conviction that they had done so has suggested to the English buyers to call for the iron, with the result that the "bears" have been forced to enter the market heavily, thus forcing the price up rapidly. On Tuesday morning on the resumption of business the "bears" were still buying to cover their commitments, and the price of G.M.B. advanced sharply from 52s. 1½d. to 54s. 3d. Cleveland and hematite followed, advancing 2s. 3d. and 2s. respectively. Since much of the iron so bought for cover at 52s. to 54s. had been previously sold at 42s., the losses of local speculators have been heavy, and some of the smaller operators are already understood to have succumbed.

MINERALS.—The serious falling off in pig iron shipments is noteworthy in view of the price movements noticed above. The decrease last week is nearly 4,000 tons, and for the four months and a half of this year amounts to 81,298 tons. The shipments have indeed been only little more than one-half the quantity of the corresponding period of last year. Coal shipments, on the other hand, continue to exhibit the remarkable expansion noticed during the past two months. As before, the East Coast ports show a large proportion of the increase; the port of Methil, for example, recently acquired by the North British Railway, advancing rapidly into a prominent place. The increase for the year so far is 91,031 tons, or about 5 per cent. on the total for the period.

ENGINEERING.—The tunnel under the Hudson, which is being driven under the care of a young Glasgow man, Mr. Ernest W. Moir, formerly on Messrs. Arrol's staff at the Forth Bridge, is now making more rapid progress. The distance tunnelled is now about three-fifths of the whole. The shield and accompanying apparatus for excavation were made by Messrs. W. Arrol & Co., and were illustrated in these columns some months ago.

SHIPBUILDING.—For the first time for some years the Fairfield Shipbuilding and Engineering Company are about to build a sailing vessel, Messrs. Gibson & Clark having contracted with them to build a vessel of 2,300 tons for their "Pass" Line of sailing ships. The vessel will be a four-masted barque, built of steel, and will have a deadweight capacity of 3,900 tons. The contract price is said to have been £23,000, or £10 per ton.

THE DEEPENING OF THE RIVER CART.—The River Cart, upon whose banks the town of Paisley is situated, and which has hitherto been a shallow and unsavoury stream, has been deepened and rendered navigable from Paisley to the Clyde. The work was commenced in 1887, and has now been completed, the river having been opened for traffic recently. Paisley has become a seaport, and now steamers will sail not only for the ports on the coast, but even to foreign ports. The depth of the river is now 18ft. at spring tides, and 16ft. at neap tides. The width of the stream has been increased from 80ft. to 180ft. The work has been carried out under the direction of Messrs. Bell & Miller, engineers,

Digitized by Google

Glasgow, the contractors having been Messrs. Ireland & Mitchell. The cost of the scheme has been £130,000. This sum has been obtained on loan secured by a power of taxation by the Cart Trustees upon the inhabitants of Paisley to the extent of a maximum assessment of 3d per £ on the rental, one-half payable by the landlord, and one-half by the tenant.

(From our own Correspondents.)

LIVERPOOL, 20th May, 1891.

The Pacific Steam Navigation Company.—From the report of the directors for the past year, just issued, it appears that the earnings of the company have been seriously affected by the late strikes, high price of fuel, and the competition in the Straits and West Coast service; also by the diplomatic troubles between this country and Portugal early last year. The profit on the working account is £157,071. The cost of coal was £353,164; repairs, £141,446; wages, £283,791; expense of management, £66,587, or 5 per cent. of the gross receipts; sending officers to the Pacific coast, £3,000. £127,817 is written off for depreciation, and £26,676 for the boiler fund. The book value of the fleet and property stands at £1,307,362; twenty-one West Coast steamers are valued at £436,935, or about £12 8s. per ton—rather a high estimate; fifteen ocean steamers are valued at £777,662, or about £12 per ton, and as this includes such steamers as the "Oruba," "Orizaba," &c., the price is a fair one. The underwriting account stands at £215,185, or 16 per cent. of the book value of the property. Two dividends of 10s. and 8s. per share respectively have been paid, carrying forward to 1891 the sum of £13,000.

The Transatlantic Cattle Trade.—The report of the Departmental Committee of the Board of Trade and the Board of Agriculture, appointed by Mr. Chaplin to inquire into and report upon the Transatlantic cattle trade, was issued last Saturday, and the following is a brief summary of the principal recommendations of the Government:—Cattle should not be carried on the bridge decks or poops; nor under temporary shelter on the upper deck; adequate artificial ventilation to be provided in lower decks; they should not be carried anywhere so as to interfere with the navigation of the ship or the lowering of boats, the fittings to be strong enough to resist the greatest possible strain. The committee consider that the well-being of the cattle depends to a large extent upon the efficiency of the cattlemen, and recommend four men to every 100 head of cattle; "deadheads" or "stiffs" to be discontinued; the foreman and assistants to be under the authority of the captain. They consider that the Board of Agriculture should make regulations as to the parts of the vessel which may carry cattle and the space to be allowed for each; to the size and fittings of pens and passages, to the lighting and ventilation; and that powers of inquiry with regard to casualties and losses of cattle during transit should be granted, similar to those now possessed by the Board of Trade.

LEEDS, 20th May, 1891.

Iron and Steel Trade.—There is little or no improvement in the demand in the finished iron and steel trades, and just now, owing to the holidays, business is exceedingly quiet. Last week few firms were really busy. Quietness also then characterised the engineering trade, though, of course, some establishments are still in the position of keeping their hands fully employed.

The Coal Trade.—All classes of coal are in fair demand at prices which have ruled for some time.

SHEFFIELD, 20th May, 1891.

Iron and Steel.—Most of the forges and rolling mills commence work again to-morrow morning, which fact goes a long way towards proving that business is fairly good on the whole. No fresh orders of importance are coming forward for a while, the last good "lines" being the 3in. and 4in. all-steel plates for the "Hood" and "Revenge," by Messrs. Chas. Cammell & Co. Other plates of a similar character are to be made by Messrs. John Brown & Co. and Messrs. Vickers, Sons, & Co., River Don Works. The latter firm are now busy with their Russian order of all-steel plates. It is satisfactory to know that our own naval authorities are fully alive to the importance of having a number of the swift cruisers protected by thin all-steel plates. The Parkgate Steel and Iron Company have issued their twenty-seventh annual report, which states that during the past year the company experienced a greatly decreased demand for iron and steel, with a considerable reduction in price. There has been no reduction in fuel and very little in labour; the company have recently purchased sixty 10-ton waggons at a cost of £3,900. The rolling stock now consists of seven locomotives and 533 waggons of all kinds. The net profit on the year's working is £13,000, out of which it is proposed to pay a dividend of £3 per share, to write off £3,000 for depreciation, and to carry forward £1,035 12s. 3d. to next year's account. The subscribed capital of the company is £300,000, of which £225,000 is paid up. This company possesses one of the best modern plate mills extant for the production of boiler and ship plates, angles, &c.

Coal.—There is practically no change to report. Fuel of all kinds is dear and scarce; at present there appears no signs of a reduction in price. House coal is in great demand, and likely to remain so, judging by the weather recently experienced.

The Sheffield Society of Engineers.—This Society are to-day paying a visit to the Earle's Shipbuilding and Engineering Company, of Hull, by kind invitation of Mr. A. E. Scaton, the general manager and director.

Cutlery.—There is a slight increase in the demand from America, with which country trade has been at a standstill for six months. Two or three good "lines" for mixed qualities have come in lately, the best class predominating. In joiners' tools there is a good business doing with German houses, and also with the English Colonies.

NORTH STAFFORDSHIRE, 20th May, 1891.

The Iron Trade.—We have the general Whitsuntide holiday at the various local works, and in some cases the state of trade is so bad that they will not be started till Monday next. There is no improvement to show, either in prices or demand, while on the other hand there is no diminution in the cost of production. Several works are being carried on at an actual loss, and short time is the order of the day.

The Pottery Trade.—The arbitration was concluded last Friday, and the umpires have undertaken to give their award on Monday next. If any alteration is made in the rate of wages it will date from that day. Some startling evidence was adduced as to the unprofitable state of this industry. The award is awaited with great interest and some anxiety by both sides.

LEICESTER, 20th May, 1891.

Wool Spinning and Yarn Trade.—Though the approach of the Whitsuntide holidays has for some little time back deterred many buyers from operating, still there has been a fairly satisfactory turnover. The market remains very firm; prices rule about as follow:—Deep-stapled fleeces of good quality, 23s. to 23s. 6d. per tod; superior, 24s. to 25s. per tod; choice lots, with large proportion of Shropshires, 26s. to 26s. 6d. per tod. The nearness of the advent of the new clip on the market to some extent curtails operations, and there are many indications that a heavy turnover will be made when it is offered. It is generally thought that the total quantity will be under the average and choice lots rather scarce. Spinners are fairly busy, and an average quantity of new business is on offer, but the old question of unremunerative prices remains and blocks business.

Hosiery Trade.—There is an increase of activity in this industry. The fancy department is considerably better off for business, whilst the underwear department in medium and heavy woollens is busy. The Cashmere hose trade is rather quieter, but, on the whole, the outlook is more cheerful generally in this industry.

Boot and Shoe Trade.—Business is very depressed. There was some activity immediately preceding Whitsuntide in completing orders, but the influx of new orders is very meagre, and the trade is certainly under the average. A few houses are keeping all departments on full time, but many factories are only working part time. The leather merchants find trade very dull and buyers cautious. Nevertheless the market remains firm, and there are few inducements to buy speculatively.

SWANSEA, 20th May, 1891.

Tinplates.—Some interesting statistics have been published regarding the wages of tinplate workers, which go some way to show that notwithstanding the design of the McKinley tariff to keep Welsh tinplates out of the American market, there is still considerable room for reductions in cost of manufacture that may, in a great measure, frustrate the attempts of the Protectionists. The average earnings per week of the various workers are given as follow:—Rollers, £2 14s. 1d.; doublers, £2 3s. 6d.; furnacers, £2 0s. 11d.; behinders, 19s. 9d. (these are usually youths between seventeen and twenty years of age); shearers, £2 11s. 5d.; head annealers, £2 10s. 4d.; assistant annealers, £1 16s. 4d.; packers, £1 9s. 2d.; tinmen, £2 8s.; washmen, £2 8s. (many only from twenty to twenty-one years of age); risers, 16s. (youths from seventeen to twenty years of age); assorters, £2 8s.; boxers, £3 17s. 9d., a sum which includes £1 2s. to £1 5s. per week for an assistant.

Coppermen's Strike.—A remarkable dispute has occurred at Messrs. Vivian's Hafod Isha Works, where, one of the men having left the union, his fellow employés declined to work with him, and demanded his dismissal. The masters not seeing their way to do this, about 300 men have thrown up their employment.

BARROW-IN-FURNESS, 20th May, 1891.

Hematite.—There is a steady trade in hematite pig iron, but the consumption is not increasing at the rate at which prices have lately been advancing. Ordinary qualities of hematite have gone up to 54s. net cash, in consequence of the operations of a "ring" or "corner," but this is no indication of the life of demand. Makers have been quoting 51s. 6d. to 52s. 6d. per net f.o.b. for parcels of mixed Bessemer numbers, but the holidays have intervened, and caused, at any rate, a temporary cessation of business. Stocks have been further reduced to the extent of over 7,000 tons, and they now stand at 150,000 tons in the aggregate. There are still only thirty-nine furnaces in blast, and thirty-eight standing idle.

Steel.—The prospects in the steel trade are rather better, although the works are stopped for a week during the holidays. The Bessemer rail department has been strengthened by the receipt of new orders at £4 11s. 6d. per ton for heavy sections, and there is every reason to expect large contracts from shipbuilders for material. Steel plates are quoted at £6, angles at £5 10s., and steel boiler plates at £6 15s. per ton. The business doing in hoops is steady at about £6. Heavy castings are in good demand, and likely to remain so. Billets, slabs, and blooms are quiet, and the trade in tinplate bars is quiet.

Shipbuilding.—Fewer orders are offering in the shipbuilding department, but it is known that increased activity may be expected at the Barrow yard during the summer months, and that engineers, ironfounders, and boilermakers will participate in the improvement.

Iron Ore.—There is a quieter demand for iron ore, and raisers are not making any profit. They are selling good average best qualities at 10s. per ton net at the mines, and they have large stocks in hand, and have, in many cases, closed their mines owing to the unremunerative trade offering.

MIDDLESBROUGH, 20th May, 1891.

Pig Iron.—There was a very small attendance at the market yesterday, and a general disinclination to do business. In fact the market was completely disorganised by the large advance in prices reported from Glasgow, and prices of makers' iron here are purely nomimal, there being a large difference between those of buyers and sellers. Merchants quoted from 42s. 6d. to 43s. per ton for No. 3 G.M.B., but buyers would not pay more than 40s. 6d. or 41s. Middlesbrough warrants have gone up to 43s. 3d. per ton sellers, and 42s. 9d. buyers. This difference of price between makers' iron and warrants may make holders of the former send their iron into the stores in order to sell it as warrants, since they will be able to get more money for it. It is impossible to get reliable prices at present for the lower qualities of pig iron, as holders have ceased to quote owing to the market being so uncertain.

Shipments.—The shipments of pig iron are still well kept up, 21,730 tons being despatched last week, making a total of 46,619 tons up to the 16th of the month, as against 35,878 tons for the same period of May, 1890. Of the 46,619 tons, 18,145 tons went to Scotland, England and Wales took 4,685 tons, and 23,789 tons went to foreign parts.

Manufactured Iron and Steel.—Quotations for both manufactured iron and steel are rather easier, but makers report that during the past few days they have secured one or two contracts. Common iron bars are £5 10s.; iron ship plates, £5 10s.; iron ship angles, £5 7s. 6d; steel ship angles, £5 15s.; steel ship plates, £6, all less 2½ per cent. and f.o.t. at makers' works. For heavy steel rails £4 10s. per ton is still the quotation. 21,829 tons of manufactured iron and steel have been shipped from this port this month.

NEWCASTLE, 20th May, 1891.

The Holidays.—In accordance with old-established custom the whole of the principal works in the district, including shipyards, engine factories, and collieries, have suspended operations for the Whitsuntide holidays, and industrial matters are consequently somewhat out of gear. Things, no doubt, will have returned to their normal condition by the end of the week.

The Coal Trade.—There is still a good deal of activity in the local coal trade, the qualities used for manufacturing purposes being most in demand. The Northumberland miners have declined to submit to a small reduction of wages recently asked for by the coal owners, and the latter have intimated their intention to abandon the claim for the present, the recent improvement in trade having made it possible to continue present rates without serious loss. The improvement, however, is not of such a nature as to afford ground for the belief that it will last for any lengthened period, and it is probable that in the course of a few weeks the claim for a wages reduction will be renewed.

New Companies.—The prospectus has just been issued of "The Tyne Shipping and General Investment Trust, Limited," which has been established for the purpose of purchasing or effecting exchanges of shares in shipping. The capital is to be £100,000, in shares of £10 each, and one-half of these are now offered to the public for subscription. The directors are all local gentlemen connected with shipping, and the registered offices are at 6, Mosley Street, Newcastle. The mortgage debentures of Messrs. W. B. Reid & Co., Leases Brewery, Newcastle, have been fully applied for, and the allotment will take place this week.

The Elswick Ordnance Works.—Several departments at this great establishment are still very slack, but it is understood that orders of importance have lately been received, and an early return of briskness is anticipated. Some new machinery for forming, by means of hydraulic pressure, various accessories required in gun construction has just been put in operation, and it is said that the results are extremely satisfactory. The iron and steel articles produced are superior in finish to ordinary smith work, and the cost of manufacture is considerably less.

MR. KEELY ON LATENT FORCE.

SOME years ago we heard a great deal about Mr. Keely and his motor, which was to revolutionise all our mechanical notions and our industrial methods, but the subject was never seriously taken up by engineers or scientific men, and Mr. Keely, failing to give any explanations which were intelligible to ordinary men, was practically laughed out of court. He, at least, still believes in the correctness of his ideas, and has endeavoured to enlighten the world regarding them in the current number of *Lippincott's Magazine*, but we confess frankly that we cannot make much of his explanations.

Some time ago Mr. Keely was asked, What is the amount of energy that you get out of, say, twelve drops of water when decomposed into ether? and he replied "that from that amount of water a force can be developed that will fill a chamber of seven-part volume no less than six times with a pressure of ten tons to the square inch." Questioned further, if so many foot-pounds of energy were put into vibratory motion, how many foot-pounds could be got out of it, he replied that "all molecular masses of metal represent in their interstitial molecular spaces incalculable amounts of latent force, which, if awakened and brought into intense vibratory action by the medium of sympathetic liberation, would result in thousands of billions more power in foot-pounds that that necessary to awaken it. The resultant development of any and all forces is only accomplished by conditions that awaken the latent energy they have carried with them during molecular aggregation. If the latent force that exists in a pound of water could be sympathetically evolved or liberated up to the seventh subdivision or compound-inter-etheric, and could be stored free of rotation, it would be sufficient to run the power of the world for a century."

In view of these possibilities the exhaustion of our coalfields is a matter of little moment. While wishing to be charitable to Mr. Keely, we must say that these statements look uncommonly like nonsense, lightened by an occasional glimmer of sense. Still, men who have some claim to be considered scientific say that "Keely has seemingly demonstrated the discovery of a force previously unknown to science."

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 269, Strand, London, W.C.*

FRIDAY, 22ND MAY, 1891.

MR. PLIMSOLL AND TRUSTS.

MR. SAMUEL PLIMSOLL, who has long had the sailor under his special care, has widened his sympathies so far as to include the general public. In an alarmist article, contributed to this month's *Nineteenth Century*, he has sounded a note of warning against the growth of trusts, syndicates, and "corners." In sounding this note, however, Mr. Plimsoll is a little late in the day, as he should have let us know the dangers of trusts before they came upon us, and not, according to him, after they are in full flood. Moreover, the tone he adopts would seem to indicate that he thought he had discovered the existence of these monsters of modern industry and commerce, and that they had grown with mushroom-like rapidity. Now, neither of these things is quite true. Many economists and some few journals —*Industries* being a good instance—have repeatedly noted the gradual growth of these combinations, have pointed out their elements of strength and their elements of weakness, and, while not suggesting any legislative interference at present, have indicated that an attitude of watchfulness is necessary in the public interest. Mr. Plimsoll gives a list of seventy-one "trusts," which, he says, have been formed in the United States in two years. Mr. Plimsoll does not always give the official title of the combinations, and he classes under the generic name of trust some combinations that, perhaps, are scarcely entitled to be so classified. Moreover, they have not all been formed in the past two years. In fact, very few of them have. The Standard Oil Trust, for instance, included in Mr. Plimsoll's list, was formed in 1882, after the very close co-operation of its constituent companies for ten years previously. The "Standard" is certainly a powerful and successful combination, but it has been the growth of years, and is, moreover, probably the only entirely successful and secure trust in America. The others have had greater or less difficulty in consolidating themselves, and some of them have passed through the experience of the Copper Syndicate. Many others of the trusts upon the list have been in existence from three to five or six years. In spite of Mr. Plimsoll's unsoundness as to matters of fact, the main purport of his paper certainly entitles it to attention. The unregulated growth of trusts might, as he argues, result in a practical re-imposition of the restrictions upon trade which were withdrawn when our tariffs were almost, if not altogether, abolished. It is a common observation in America that the great industries there will, ere long, be able to dispense with a protective tariff, because they will be able to protect themselves—that is, that they are nearly powerful enough, by means of trusts, to fix arbitrary prices for their commodities, and thus to withdraw them from international competition as effectually as they are now enabled to do by the protective tariff. It is to be noted that while a tariff protects a home manufacturer from external competition, it does not protect him against the competition of his own countrymen; indeed, it often enhances that, whereas a trust effecting arbitrary fixation of prices abolishes competition altogether. Thus, in protecting the producer and his group of capitalists until they were strong enough to stand alone, the American legislatures have unintentionally created formless and irresponsible power, at once able and willing to continue, under another guise, the tariff which the legislature was prepared to abolish. So far as the United States and Canada are concerned, the evolution of trusts must necessarily be watched with considerable anxiety. Several of the States of the Union have legislated on the subject, and, even apart from special legislation, there is considerable doubt as to the legality of trusts in common law. The growth of trusts in countries where protective tariffs are highly developed suggests a connection between trusts and tariffs. And the existence of this connection is confirmed by the rarity of trusts in this country, the only Free Trade country in the world. It is not difficult to discover the connecting link between trusts and tariffs. A tariff enhances domestic competition until this competition becomes ruinous, then the combination arises as a last hope. The last hope sometimes succeeds beyond expectation, and a trust is consolidated. In our own country competition, keen enough in many branches, is not so keen as it is in America. Our business men, as a rule, are less ambitious; social influence may be gained in this country with moderate means, in America with enormous means alone. There is proportionally in this country also, perhaps, a larger number of persons of more nearly equal abilities for the conduct of considerable affairs than there is in America. There are numerous other differences between the economic and social conditions of this country and those of the United States, which tend to suggest that any extensive adoption of the trust here is unlikely; and that, however necessary even the most drastic legislative interference may become in the United States and in Canada, the time has not yet arrived when such need be pressed in this country. It might be argued, with some probability of success, that the existing law is sufficient to prevent the growth of the trust idea. The main argument against the trust is that it is opposed to public policy because it "acts in restraint of trade" and tends to raise prices. Now, whatever "acts in restraint of trade" is liable to be prohibited under the common law; and it would take some trouble to devise a scheme at once more specific and less likely to be used as a means of escape than that already provided. Again as to the tendency to raise prices, it is pointed out by the apologists of trusts that the concentration of skill and capital, and the diminution of administrative expenditure resulting from the formation of a joint-stock company, results also, and in a greater degree, from the formation of a trust. It is argued that the saving so effected would enable the trust at once to make a larger profit for its constituents and to charge a lower price to its customers. Unfortunately this philanthropic intention is seldom fully realised. The trust succeeds, as a rule, in the first endeavour, and finds means to avoid engaging in the second. Yet, on the whole, though the trusts of the United States and Canada do not reduce prices much, if at all, they do not as a rule enhance prices—they only keep them from falling. It is an evidence of the purely arbitrary character of their price lists, that they have generally arrested the fluctuations at the point at which prices stood when the trust was formed. Thus, in the case of the Standard Oil Company, oil

Digitized by Google

was declining rapidly, prices had fallen fully 10 per cent. per annum between 1861 and 1872, while there was no trust; fully 7 per cent. per annum from 1873 till 1881, while there was an incipient trust; and only 2¼ per cent. per annum during the maturity of the trust. It is impossible to say whether the existence of the Standard Oil Trust makes petroleum cheaper or dearer to-day than it would have been had there been no Standard Oil Trust. It is possible that had the fall of prices continued for some time the capital devoted to the business would have found some more remunerative outlet, and there would thus have been diminished production and enhanced price until, perhaps, the whole of the fall, or more than the whole of it, might have been recovered. Many trusts can point to reduced price lists as a justification of their existence, but after all, the gauge is delusive: the question, which in most cases cannot be answered with any reasonable approximation to accuracy, is—what would prices have been without these combinations, would they have been less or more? In failing to grasp that there is a possible good side to the trust, and that judged by the standard of his own choosing—viz., the standard of the effect of the trust upon prices—Mr. Plimsoll errs so decidedly, that an apologist of the trust would have no difficulty in knocking Mr. Plimsoll's warning and its supporting argument into fragments. Apart from definite statistical proof, which in the nature of the case does not appear to be possible, there can be little doubt that as regards benefit or injury to the community the presumption is against the trust. The trust would have no reason for existence unless prices tended to be reduced by competition. As regards its other alleged function, there are advantages in comparatively small and carefully supervised concerns which to a large extent outweigh the economies effected by administration on a large scale. Though mere cheapness cannot be represented as a social end, it is undoubtedly to the benefit of the community in general that no section of it should be permitted to place a ransom price upon its labour or upon its commodities. Since no more effectual means of preventing this "cornering" than the commonplace means of competition has yet made its appearance, it would seem as though the justification of the trust, from its own point of view, were its condemnation from the point of the public. There was something in Adam Smith's reproach, that traders never meet together but they "hatch some public mischief," for, although combination has its legitimate uses, it may, as a combination of labour or of capital, be pushed so far as to constitute itself a public nuisance. Thus, while a prohibition of the practice of walking along a street arm in arm might justly be regarded as oppressive, a combination of persons who chose to march in a body enlaced arm in arm from one side of the street to the other would probably find that it had transgressed against the public sentiment, if not even also against the law of every civilised country. The desire on the part of the trusts, both in this country and in America, to establish themselves in public favour by showing that, on the whole, they are a benefit to the people at large, must certainly tend to impose a natural limit to arbitrary management. The same force would even more decisively make itself felt in this country, and this, coupled with the fear of legislation following unwise exercise of opportunities, may be trusted to keep the trust question in check for some time to come.

THE ANALYTICAL CHEMIST AND THE INSTITUTE OF CHEMISTRY.

Although it is now nearly six years since the Institute of Chemistry obtained its charter of incorporation, the public are only now slowly beginning to realise the importance of having a body of qualified analytical and consulting chemists in their midst. In our issue of last week we gave a report of the conference held at Burlington House, at which a series of interesting papers were read and discussed, which show that the Fellows of the Institute have now become keenly alive to the responsibilities which rest upon those practising this comparatively young profession. As is generally the case when a new idea is being developed, there were differences of opinion as to the best way of protecting the public from the impositions of quackery on the one hand and the evils of professional unionism on the other. We have so recently given our readers a historical sketch of the inception and growth of the Institute (see *Industries*, Vol. X., page 163), and urged the advisability of the acquisition of compulsory powers and the adoption of a practice qualification for those entering the profession, that we do not propose to further discuss the internal management or constitution of the Institute. Mr. Hehner, at the conference last week, read a paper entitled "The Analytical Chemist in Relation to the Public, the Profession, and the Institute," and it is the first of these relations to which we wish to draw the attention of our readers at the present time. There can be no doubt that the professional chemist is rapidly becoming of more value to the public, but the increasing numbers of men who style themselves analysts, analytical chemists, and so forth, render it necessary that an authoritative warning should be given to the public by the Press that it will do well to examine carefully into the credentials of its chemical advisers before entrusting them with any work of responsibility. It may be difficult for the public to realise that the Chemical Society, which has recently celebrated its jubilee with such a flourish of trumpets, is simply concerned with the advancement of the science of chemistry, and that its Fellows as such are *not* trained to undertake the elucidation of commercial and technical problems. In the earlier days, when the application of chemical analysis to raw materials, foods, and drugs was being demonstrated as useful to the public welfare, the professor and the scientist acted as pioneers in this demonstration. At the present time we owe some thanks to these earlier investigators, who not only endeavoured to educate the public to the proper understanding of the importance of the purity of articles of commerce, but at the same time laid the foundations of the modern methods by which adulteration and sophistication may be detected and accurately estimated. The analytical chemist at the present day is a professional servant of the public, and it is essential that he should not only discharge his duties with exactitude and promptness, but should be acquainted with the exigencies of trade, the requirements of buyers, the difficulties of manufacture, and should be in touch with the business in which his aid is generally indispensable. The Institute of Chemistry was founded to supply the public with such men, and its curriculum and professional examinations are supposed to be arranged with this object in view. We take it that the public will now have the advantage of knowing that a "F.I.C." is qualified to assist in such commercial problems, and we may further take it that a "F.C.S." is simply a member of a time-honoured institution for the furtherance of pure chemistry. The latter may possibly be a teacher or *dilettante* in chemical science, but not have a particle of professional knowledge. We make these remarks, as we know that there is a tendency on the part of public bodies to regard the Fellowship of the Chemical Society as a guarantee of professional ability; also that some local authorities consider that a medical man, or a pharmaceutical chemist, as such, is qualified to certify as to the purity of foods and drugs. We wish to urge the importance of discriminating between the various divisions of professional ability, and to show the improbability of one man being proficient in several branches of knowledge. Formerly, in a small town, the surveyor and the medical officer were able to advise on all technical matters which were likely to arise in the municipal affairs, but with the development of trade and the progress of local industries the public require the services of the civil and sanitary engineer, the gas examiner, the analyst, and the electrician, whilst the medical officer himself may well devote his time to work which pertains to hygiene and sanitary science. We regret to see that in an important London vestry the authorities have thought it advisable to still continue to combine the appointments of medical officer of health, foods and drugs analyst, and gas examiner. In this particular case the medical Press, as representing the medical profession, and the Institute of Chemistry, on behalf of analytical chemistry, pointed out the anomaly of an appointment with triple duties of such diverse character, and we doubt whether the Local Government Board will confirm such a course. There is as little relationship between the duties of a medical officer of health and a gas examiner as between those of a veterinary surgeon and a dentist, and we trust that it will not be long before the public recognises that the analysis of water and gas, of foods and drugs, and articles of commerce cannot be done efficiently or satisfactorily in the public interests except by highly trained and properly certified professional men.

In our recent articles we pointed out that the Institution of Civil Engineers had successfully overcome a similar difficulty, and that, although it is still open to any unqualified person to put "C.E." after his name, still the public have found out that membership of the Institution of Civil Engineers is a generally satisfactory guarantee of proficiency. The breaking down of the quackery attending the use of "C.E." by unqualified men was, however, an easier task than that which the Institute of Chemistry has before it, in disillusioning the public as to the absence of any professional value in the Fellowship of the Chemical Society. Professor Odling expressed himself very strongly on this point at the recent conference, and showed that it was extremely undesirable that the Fellowship of the Chemical Society should be considered in any degree tantamount to an attestation of scientific or professional ability. We hope that the Council of the Institute in their own interests, as well as in the interest of the public, will give his views on this subject the widest publicity. We are inclined to think that more can be expected from greater activity on the part of the Council of the Institute than from attempts to rouse the public from their apparent apathy and lethargy in matters which are of such vital interest to public health and commercial morality. The conference held last week is the first of a series of semi-annual meetings which the Council has arranged to be held in London, and we hope that, by selecting subjects of general interest for discussion, the Institute will demonstrate by its activity in this direction that its Fellows are worthy of the confidence of the public. We are aware that some will urge that such proceedings are of the nature of an advertisement, and derogatory therefore to the profession, and are prompted by motives of self-interest rather than for the public welfare, but, if our space permitted, we could readily show that beneficial results to the public must necessarily follow from a knowledge of the true scope and aim of the Institute of Chemistry.

NEW SALOON PADDLE STEAMERS.

During last month there were launched from various shipbuilding yards on the Clyde five saloon paddle steamers, which have been constructed with a view to their being employed in the ensuing summer passenger traffic, and three of this number have already been completed and placed on the measured mile for their speed trials. The largest—the "St. Tudno"—was constructed by the Fairfield Shipbuilding and Engineering establishment, Govan, her principal dimensions being:—Length, over all, 277ft.; breadth, 22ft. 6in.; depth, moulded to upper deck, 19ft. 6in.; and gross register tonnage, 900. This vessel is intended to conduct a new express service between Liverpool, Llandudno, and the Menai Straits, the double journey to be accomplished within twelve hours. The graceful character of her lines forward and aft reveals the fact that speed was of primary importance in the consideration of her design. Twenty-two statute miles per hour is the speed aimed at, and to realise this a pair of powerful compound diagonal surface-condensing engines have been fitted, with cylinders of 51·5in. and 93in. in diameter respectively, and a stroke of 5·5ft. Steam is provided from two double-ended steel boilers at a working pressure of 115lb. per square inch. The principal apartments of the ship are situated on the main deck, and are most elaborately furnished, every convenience being embodied in the saloons, dining-rooms, smoking room, &c., that ingenuity can suggest for the comfort of passengers. The "St. Tudno" had a satisfactory preliminary trial of her engines in the Firth of Clyde on the 9th inst.

On the same date the "Woolwich Belle" completed her official measured-mile trials, and had a protracted run of six hours' duration at full power. This vessel has been built for the Woolwich and Clacton-on-Sea Steamboat Company, for passenger traffic between London and Clacton-on-Sea, by Messrs. William Denny & Brothers, Dumbarton. She is built of steel throughout, and measures 200ft. in length by 24ft. beam, her registered tonnage being about 400 tons. Her construction is that of a promenade deck steamer, the after first-class saloon being carried out to the ship's side, below which is the dining saloon, while the second-class saloon is situated forward below the main deck. To enable the steamer to pass under London Bridge at any state of the tide she is provided with a funnel which telescopes into the uptake, while the mast is also adapted for lowering. Compound surface-condensing engines are fitted, which enabled the vessel to steam on the official trial for the full period of time at an average rate of about 17½ statute miles per hour, the engines running throughout from start to finish without the slightest hitch. The "Woolwich Belle" has a neat and fascinating appearance, and this, taken along with the results achieved, fully maintains the honours already earned by Messrs. William Denny & Brothers as regards paddle-wheel steamers.

Digitized by Google

The new "Lord of the Isles," was placed on the measured mile in the Gareloch on the 9th inst. This splendid paddle steamer has been built to replace the old vessel of the same name, which was purchased at the end of last season by the Victoria Steamboat Association of London, and which plied on the Clyde from 1877. The new steamer, which is 255ft. in length, by 25ft. beam, by 8·5ft. in depth, has been built and engined by Messrs. D. & W. Henderson & Co., Partick, for service between Glasgow and Inverary. In general appearance she resembles her predecessor, the principal difference being in the arrangement of the saloon, which in the new steamer occupies the whole breadth of the main deck, whereas in the old steamer a passage way was left between the saloon and the sides. This improvement admits of greater space being utilised for the promenade deck, which extends for three-quarters of the length of the ship. The saloon is tastefully decorated in white and gold, the furniture being of black walnut upholstered in terra cotta velvet. The dining-room is situated below the main saloon, and the officers and crew are berthed forward under the main deck. A great deal of interest is at present being centred on the Clyde in the new steamer, and, in virtue of her greater length and more powerful engines, it is confidently expected that she will completely eclipse in speed the performance of the first "Lord of the Isles," which used to perform the daily run of 228 miles at an average speed of 20 miles per hour.

Less palatial than the "Lord of the Isles," although, perhaps, not less comfortable, is the "Marchioness of Lorne," built by Messrs. Russell & Co., Greenock, to augment the Clyde service of steamers belonging to the Caledonian Steam Packet Company. This vessel is, practically speaking, a replica in miniature—being about 100ft. shorter—of the now famous "Duchess of Hamilton," constructed last year by Messrs. Wm. Denny & Brothers for the same company. The "Marchioness of Lorne" is built of steel throughout, of somewhat heavier scantlings than is usually adopted in Clyde river boats, as she is intended for the winter traffic between Ardrossan and Arran. In this vessel the hurricane deck runs right forward to the bow, the fore and main saloons, which extend to the sides, being between this deck and the main deck, with first and second class dining saloons below. Generally speaking, in this class of boat, triple-expansion engines are rather the exception than the rule, but with a view to keeping well abreast of the times the owners of the "Marchioness of Lorne" specified that she was to be fitted with this type of machinery, and the construction of the same was entrusted to Messrs. Rankin & Blackmore, of Greenock, the cylinders being 17·5in., 30in., and 40in. in diameter respectively, with a stroke of 60in. Steam will be supplied by two boilers of the Navy type, working at a pressure of 140lb. per square inch with forced draught on the closed stokehold principle. The dimensions of this vessel are:—Length, 154ft.; breadth, 20ft.; and depth to hurricane deck, 13·25ft.

The "Ravenswood," built by Messrs. S. M'Knight & Co., of Ayr, for Messrs. P. & A. Campbell, for their passenger service between Bristol and Tenby, is another vessel in which attention has been given to secure the much desired quality of speed. This vessel is 15ft. longer than the "Woolwich Belle," with the same beam, and is fitted with a diagonal surface-condensing engine, the cylinder being 56in. in diameter with a stroke of 72in., steam being supplied from two haystack boilers. This steamer has deck saloons forward and aft, with a promenade deck 160ft. in length, and, as in the other vessels, every conceivable provision has been made for the safety and comfort of passengers.

Letters to the Editor.

TYPE-WRITER FOR THE BLIND.

To the Editor of "Industries."

Sir,—A slight error occurs in your description of our Braille-type writer in your issue of the 8th inst.

The fourth key is depressed only for spaces between words, or when it is necessary to advance the traveller without embossing the paper. The traveller advances automatically for spaces between letters or parts of a letter after depressing one or more of the three keys which actuate the punches.

Yours, &c.,
Cockburn, Phillips, & Montgomery.

Westminster, S.W., 15th May, 1891.

THE DECIMAL SYSTEM.

To the Editor of "Industries."

Sir,—The reply given by the Chancellor of the Exchequer to the influential deputation which recently waited upon him to urge the introduction of the metric system of weights and measures, as the first stage in the adoption of a complete decimal system, must be considered by all real lovers of progress as most unsatisfactory. While admitting that the reform would be attended with great advantages, he thought that such a change would confuse almost everybody in the country, and he declined to recommend the Government to appoint that convenient instrument of delay—a Royal Commission.

The question to consider is whether even a Chancellor of the Exchequer ought to be allowed to set aside such a question, supported as it was by such a deputation, and the opinions of the Associated Chambers of Commerce and the Decimal Association. It has now been discussed for many years, and the system has been adopted by almost every country claiming to be considered civilised, and yet on the personal opinion of one man this country is to be kept at a disadvantage, not only in the matter of business but also of education. I hope that steps will at once be taken to bring public opinion to bear on the Government to at least prepare the way for its introduction. I believe that the inconvenience of the change has been very much exaggerated.

Yours, &c.,
Decimal.

London, 18th May, 1891.

ENGINEERS IN THE NAVY.

To the Editor of "Industries."

Sir,—In connection with the correspondence which has taken place in your columns recently, the following paragraph, which I have culled from one of your American contemporaries, serves to show that engineers in the British Royal Navy are not alone in their dissatisfaction of their position, and that the position of their brethren in the United States Navy is quite as bad if not worse than their own.

The writer states that "some of the reasons why competent machinists will not remain in the engineer force of the United States Navy are given by an honourably discharged one, who asserts that a good machinist is paid and treated better and thought more of outside. He can do as he pleases, and has some place to read in or do otherwise after his day's work is done, which he cannot in the navy. A good machinist certainly should enjoy the same privileges as a carpenter, sailmaker, boatswain, or gunner, for he is certainly of as much importance as any one of these, and there is no reason why he should not enjoy the same comforts as a merchant marine engineer, as he does the same duty and has to pass about the same examination. The *American Machinist* makes the sensible suggestion that machinists in the navy should be rated as warrant officers, like carpenters, boatswains, &c., as thus rating them would be likely to secure a better class of men for the service."

C. J. W.

Liverpool, 15th May, 1891.

THE NATAL GOVERNMENT RAILWAYS—OPENING OF THE EXTENSION TO THE TRANSVAAL.

To the Editor of "Industries."

Sir,—Another link in the chain of events which tend to form a united South Africa was completed to-day in the opening of the railway to Charlestown, the extreme limit of the Natal Colony and boundary of the Transvaal. The main trunk line from the coast is now completed. From Durban to Charlestown is 304 miles, and, in travelling this distance, every train has to be pulled up a total vertical height of 13,350ft., or more than 2½ miles. From Newcastle to the Ingogo the line follows the Buffalo Valley, and, in fact, runs for a considerable distance along its banks, but at this point it ascends into a subsidiary valley. The scenery all along the route is of a very interesting nature. At Ingogo we come to the first station on the new section—a distance of 283¾ miles from Durban, or 10 miles from Newcastle.

From Ingogo we run along a fairly even track until Boscobello is reached, and here we have to ascend a height of some 500ft., which is accomplished by means of the reversing station principle. This is a principle hitherto unknown in South Africa, but is very commonly used in America and Switzerland. By this means heavy grades are avoided, and it was to secure a ruling gradient of 1 in 50 throughout that the principle was adopted. It is somewhat difficult to describe, but is worked somewhat as follows:—The train coming along the main line is stopped after ascending a steep ridge. The engine then runs down a second line of rails, and is coupled on to the end of the train, which is pulled backwards above the main line on to a second ridge. The same process is again adopted, and, another ridge having been safely got over, the train proceeds on its way in the ordinary course. The reversing station principle is very interesting to watch, and this interest is all the more enhanced by the reason of the splendid view offered to the sight in ascending the various ridges. Below we see the Boscello farm, and the higher we ascend the more beautiful does the view become.

It may be mentioned that while the telegraph wire which runs in a straight line up the heights is *two miles* in length, the line has to run a distance of six. The line here runs pretty even, the ruling gradient being 1 in 50 until we come in sight of Laing's Nek. The gradient here is very steep, being 1 in 30, and in one small portion 1 in 20, which is certainly one of the heaviest grades on the line, and to overcome it two engines have to be brought into requisition for every train of any weight. From there we run a distance of four miles into Charlestown, the terminal station of the N C. Railways, and situated at a height of 5,386ft. above the level of the sea. There are only three bridges of any importance on the section. The first of these is the Incandu, just outside of Newcastle. It is an iron bridge, consisting of one span of 100ft. and two spans of 40ft., erected on solid masonry abutments, the whole forming a very substantial structure. The second crosses the Imbazan, being a one-span bridge of 60ft., and the third, which consists of one span of 100ft., bridges the Ingogo.

The scenery throughout the section is very pretty, and the district through which the line passes naturally affords special attraction to the English tourist, inasmuch as the line skirts all the memorable battlefields of the Boer War.

Just above Boscobello we catch a glimpse of the towering Majuba, which appears to frown down upon us as we rattle by, and presently we pass close to O'Neall's house, where the Transvaal Convention was signed by Sir Evelyn Wood and President Kreuger on the 24th March ten years ago, which led to the restoration of an independence that ought never to have been violated.

Ascending a little further, and looking to the right, we find straight in front of us Laing's Nek, and further on the Ingogo Heights and Mount Prospect, all of which specially attract the visitor's attention. Coming to Laing's Nek Tunnel, it may be stated that the tunnel is 2,200ft. long, perfectly straight through, and is being constructed to avoid a long detour, which would be otherwise necessary, and dangerous owing to the severe curves.

The tunnel, which is the longest and the greatest engineering feat in South Africa, was pierced on the 28th January, and the masonry work is now being rapidly proceeded with. It is expected that it will be ready for opening in September or October next. For the present the line will only be open for passenger traffic, but it is expected to be ready for the transport of goods in September. This extension leaves only now a coach journey of about twenty-four hours to Johannesburg or Pretoria, while previous to this it took three to four days *in fine weather*.

The opening ceremony was performed with the usual Colonial *éclat* and hospitality by the Governor of Natal, Sir Charles Mitchell, K.C.B., and suite, together with the leading members of the Legislative Council, who went per special train to Charlestown to meet President Kreuger, General Joubert (of Laing's Nek and Majuba Hill fame), and the deputation coming from the Transvaal as the invited guests of the Colony.

Yours, &c.,
D. W. Watt.

Natal, South Africa, 7th April, 1891.

MARINE ENGINE TRIALS.

To the Editor of "Industries."

Sir,—The Report of the Research Committee of the Institution of Mechanical Engineers, and your recent article thereon, contains much that is of interest to marine engineers. It is to be hoped that the Committee will note the suggestions you make, and extend their investigations in the directions you indicate. As you say, the importance of the subject is such as to warrant the assistance of the Government or of the shipowners of the country, and it would prove a good investment if the work were thoroughly and systematically done.

The Committee would do good service if they would help to settle in an authoritative manner the proper method of arranging steam jackets in marine engines of the type now in ordinary use. Those who are responsible for the design of the "Iona" seem to have adopted a very good plan, but one which differs very materially from the practice of some of our best marine engineers. The high-pressure cylinder was placed in the middle, and had three metals or walls around it. Counting from the inside, the first metal is the working barrel. Between the first and the second metal a space forms a steam jacket at full boiler pressure, and this is the only jacket about the engines. The space between the second and the outer wall is partly the receiver between the first and second cylinders, but mainly it is the receiver between the second and third cylinders. The jacket thus, by this ingenious arrangement, gives off heat inwards to the first cylinder, and outwards to the receivers, thus imparting heat where, according to theory, it is most efficient, and not on the second or third cylinders, as it is very often put. It thus has the effect of drying, or superheating, to a certain extent the steam where such is likely to do the most good. It is to be regretted, as Professor Kennedy mentioned in the discussion, that the apparatus designed for measuring the amount of priming had broken down, and thus prevented the investigations of this part of the trial being carried to a successful termination, for this, in conjunction with the arrangement of the steam jackets, affects fundamentally the whole question of marine engine economy. Multiple-expansion engines and steam jackets are only devices for getting rid of the evil effects of the condensation of the steam in the cylinders. It is to be hoped that the Committee will direct special attention to these matters, and give forth such a Report concerning them that in future there may be something like uniformity in practice.

Yours, &c.,
M.I.N.A.

Glasgow, 18th May, 1891.

NOTES ON PATENT LAW.

IV.

(*Continued from page* 417.)

Having now ascertained what is capable of being patented, we have in this article to address ourselves to the totally different inquiry as to what will be actually protected by a given patent grant. It is well understood that this depends in some way upon the specification which the patentee has lodged at the Patent Office, but it is important for a full apprehension of the subject that the rule should be accurately stated, and not left involved in vague and cloudy language.

Originally, then, it should be understood that a patent grant was, as a rule, made in respect of some art or craft which the patentee practised. In an old case which was tried in the time of Queen Elizabeth it was considered to be a very weighty objection to a grant of the monopoly of making and importing playing cards that the person to whom the grant was made was a gentleman of the Court unversed in trade, and was not fitted personally to undertake either the manufacturing or commercial operations of which he had acquired the

Digitized by Google

monopoly. This principle does not, however, appear ever to have obtained the force of law, although the set of opinion and authority was undoubtedly at one time in that direction. Very early in the history of our patent law the principle was clearly recognised that the grant of monopoly was made in requital of a public service rendered by the patentee in teaching the people of the realm a new trade. Hence it was at one time contended that no patent grant should be made for longer than seven years, because seven years was the ordinary period of apprenticeship, and it was considered that it would not be right to prohibit the artificers whom the patentee had instructed in his art from following the craft to which they had been brought up. This strict logic did not in the end prevail, but to this day the idea remains, so to speak, embalmed in the patent term, which is granted for fourteen years—that is, for two seven-year periods—and renewable, if renewable at all, for a further period of seven years. Indeed, so fixed has this principle of the essentially contractual nature of a patentee's right become in our patent law, that it is almost certain it would have led to the rule that a patentee must hold his patent on the condition of practising his invention, if it had not happened that the better expedient of a specification setting forth the invention in detail, to be filed at the Office of Patents and open for the instruction of the public, was thought of at the beginning of the last century.

The various steps by which the specification as originally devised came to be modified into the particular documents with which we at the present time are familiar, under the names Provisional Specification and Complete Specification, need not be traced. Enough has been said to show exactly what their bearing on the patent is, and to enable the reader to perceive how and why the rule should obtain that a patentee can only have protection for what he has disclosed in his specification. It is the disclosure, the teaching of his invention to other people, that is the meritorious foundation of the grant. If the patentee fails in this particular he withholds the consideration in respect of which the grant is made, and if the consideration fails the grant itself fails, and he is a patentee no longer except in name.

The first principle, then, is that the *patented invention* can only be something which the patentee has described in his specification, and described so that other people may learn from the description what it is and how it is to be made or performed. Hence the extreme importance of a full and accurate description, upon which, indeed, as being the very essence of the specification, and, therefore, the main condition of a valid patent grant the patentee's rights wholly depend. This description, according to modern practice, may be put into two forms. The one (the provisional specification) is a very compendious account of the matter which serves to identify the invention and to describe its nature in general terms. Great latitude of description is allowed in this document, and it is accordingly generally drawn up in very vague and comprehensive language. In its preparation the patentee often relies upon his own draftsmanship, or seeks the assistance only of such persons as he can treat with the greatest confidence, since until this is lodged at the Patent Office he has absolutely no rights in his invention as such, and any unguarded disclosure of it would amount to a publication which might invalidate the patent grant. It is indeed a most dangerous thing to attempt any exact description of an invention in the provisional specification, and this for two reasons—(1) because the provisional specification once lodged cannot be amended, and, therefore, any inaccuracy of description is irremediably fatal to the grant founded upon it; and (2) because nothing can be eventually claimed as a part of the protected invention which cannot be brought under some part of the description contained in the provisional specification. Now it often happens that during the period of nine months which the patentee enjoys for the preparation of the complete specification, he devises improvements in the details of his invention, improvements which add greatly to the value of the patent. If these improvements can be shown to be mere elaboration in detail of what was stated in general terms in the provisional specification that will be held to be a legitimate development, but if the provisional specification describes one thing and the complete specification passes that over and describes something else in its place, even though it be a mere matter of detail, the thing so substituted cannot be included in the patent, and if the attempt be made by claiming to protect it, the result will be to render the patent void.

This serious risk carries no countervailing advantage, since it does not in any way better a provisional specification to make it minute in its description. The law does not require any such minuteness, and the public are not benefited by it, since the provisional specification is not now published except in conjunction with the complete, from which full information must be obtainable. A skilful draftsman therefore aims, in the preparation of a provisional specification, at generality. He will, of course, be careful to be accurate, since inaccuracy would be fatal to the grant for which he is laying the foundation. But he will make no attempt to be precise. He will rather seek to leave as much room as possible for the modification in detail of the exact arrangements which are present to his mind as he writes. The only thing that he must needs make clear is the nature of the invention. So soon as that has been made to appear he may desist; indeed, the sooner then he gets to the signature—and eventually to the Patent Office—the better. Nothing but danger lurks in any single supernumerary word in a provisional specification.

It is perhaps safer, though scarcely necessary, to interpose the observation here that throughout this article the word "detail" is used with reference to the general scope of the invention. Many inventions—indeed, most inventions nowadays—are inventions of pieces of mechanism which may fairly be called details. Every now and then, indeed, some invention bursts upon the world of such scope, that nobody would think of belittling it by calling it a detail. The telephone, for example, was, a few years ago, a case in point, as also was the phonograph. These marvellous instruments, when first they were brought to the knowledge of the instructed world, seemed more wonderful for what they were than even for what they could do. They lay so far apart from the beaten track of invention, and even of discovery, up to that date, that probably few people who were capable of forming any opinion on theoretical grounds as to their capabilities at all believed, when first they heard them described, that the means said to be employed were at all adequate to the ends said to be attained. Whether in the construction of a telephone a straight bar magnet or a horseshoe magnet were used would, in the first description, have been the merest matter of detail. But nobody can now have a master patent for the telephone, and in all the later specifications these details are the very essence and substance of the several inventions. It would, therefore, be a great mistake in a provisional specification under a patent for improvements in telephones to refer to the improved parts in the language which would have been apt enough in the first telephone specification. The condition that the nature of the invention shall be made to appear could not be satisfied in this way, and when, therefore, the patentee is directed to generalise as much as possible in his provisional specification, the admonition must be understood with reference to the cardinal principle just laid down. Generalising does not mean using vague, still less does it mean using inaccurate language, but it means describing an invention in terms so large and elastic that they will comprehend every form, whether perceived at the present time or not, in which the essential features of the invention can be embodied. Every modification of the idea present in the writer's mind which does not destroy some one or more of these essential features, is a matter of detail only, and should not be excluded by the terms of the provisional specification.

Before passing from the provisional specification, it may be well to note that, under the new law of 1885, the filing of a provisional specification at the Patent Office does not amount to, nor does it necessarily lead to, a publication of the invention. Prior to that date the practice at the Patent Office was to publish abandoned provisional specifications, but that is not so now. A patentee who has suffered no publication of his invention during the period of provisional protection may now, therefore, abandon his provisional specification at his discretion. By so doing he incurs no further risk or detriment than that resulting from the loss of the date at which he lodged it. It may be that his invention has been re-invented or even published in the interval. If so, he may find himself anticipated by a later inventor, but he does not now commit what used to be the fatal error of anticipating himself.

This discussion of the features of a provisional specification will have prepared the reader to seize the leading characteristics of the complete specification. For, indeed, it may now be summed in a word. *Particularity* is in a complete specification what *generality* is in a provisional —its chief, indeed, its one, excellence. The words of the Act (Patent Act 1883, Sec. 5, s.s. (4) which define this requirement are:—"A complete specification, whether left on application or subsequently, must particularly describe and ascertain the nature of the invention and in what manner it is to be performed, and must be accompanied by drawings if required."

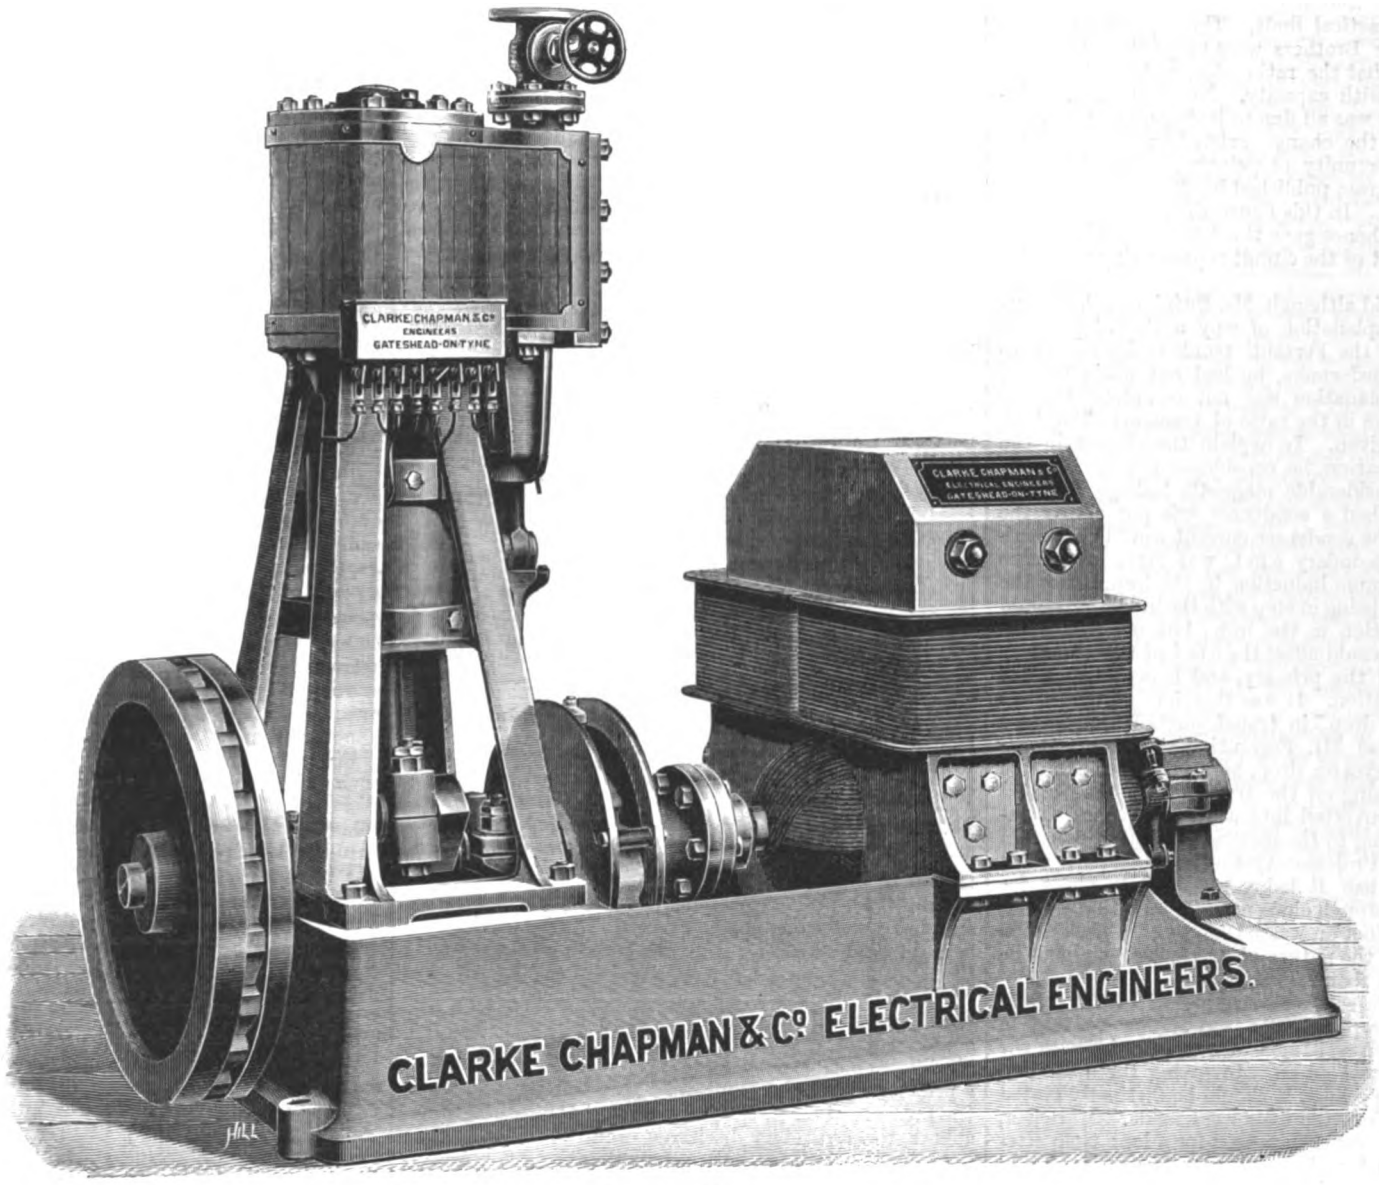
Bearing in mind what has been already said as to the purpose of the specification, the reader will readily appreciate that the particular description of this section must be a statement so precise that a reader may learn from it the inventor's secret more or less as an apprentice might learn it in the inventor's workshop. Indeed, it is hardly possible in this connection to be too precise. Those patents which break down for faulty descriptions in the specification generally fail at this point, and even accomplished draftsmen are apt to err through striving too hard to generalise the description given in the complete specification, which should be perfectly definite and minute. A very good plan, which many experienced draftsmen adopt, is to put two descriptions into the complete specification, the one couched in general terms —often a verbatim repetition of the provisional specification—and, following upon that, a detailed description, introduced by way of illustration. The freedom which the writer thus secures is of the greatest advantage to him. He makes no attempt in his detailed description to amplify, and, therefore, is under no temptation to sacrifice perspicuity to comprehensiveness. On the contrary, he sets before his mind's eye an actual specimen of the invention worked up into shape, and gives as lucid a description of that very thing as he can formulate. It may be that parts might be otherwise arranged or variously modified in form and relation—that does not trouble him at all—his general description has already conveyed that intimation, or, if he doubts that, the doubt is set at rest by a sentence expressly introduced for the the purpose. Thus, one constantly finds in such descriptions parentheses like the following:—"It will be understood that I do not confine myself to the exact form of (such and such a part) here shown," or "It will be obvious that some other arrangement of parts may be adopted than the one just described without departing from the spirit of my invention." In this way the desired elasticity may be secured in the language used, while, at the same time, the requirements of the Act as to precision are fully observed.

Another thing which aids freedom in the writer of the descriptive part of a complete specification is the recollection that it is quite allowable to include in the description things that are not included in the patent. This is, indeed, usually inevitable, since it is seldom possible to give an intelligible description of a patented improvement without adding to it as explanatory matter some description of unimproved parts which the improved are intended to supplement or supersede. In order that a patentee may not be embarrassed by the effort to distinguish all through his description between what is new and what is not new, the Patent Act of 1883 provides that a complete specification "must *end* with a distinct statement of the invention claimed." So long as this requirement is satisfied it matters nothing how much the description may in its course have been involved with old and unprotected matters. The one indispensable quality of the descriptive passages in a properly drawn specification is perspicuity. The distinctness which comes of clearly defining the invention claimed can be secured, and best secured, by a separate passage expressly devoted to the definition, and thus the draftsman is set free to pursue with undivided attention the one object of preparing such a description as will enable a competent person without further direction or experiment to make the patented article or perform the patented operation.

The proviso involved in the word "competent person" here used opens out a new topic, which we must reserve for the next article.

(*To be continued.*)

Reviews.



THE SCOTTISH RAILWAY STRIKE, 1891: A HISTORY AND CRITICISM. By James Mavor, Professor of Political Economy and Statistics, St. Mungo's College, Glasgow, &c. Edinburgh: WILLIAM BROWN. 1891.

When the history of the labour movement of the latter part of the nineteenth century comes to be written a prominent position must be given to the record of the strikes which took place and the results which followed from them, and the contemporary records will be deligently studied by those who aim at being impartial historians. The London Dockers' Strike formed the subject of a very large number of articles, but the majority of these were tinged to a very considerable extent by a partisan spirit. Probably the "Story of the Dockers' Strike," as told by Mr. Llewellyn Smith and Mr. Vaughan Nash, was the most impartial from a historical and the most useful from an economic point of view. Professor Mavor has rendered a similar service in connection with the recent railway strike in Scotland, and, while recognising that as yet it is not possible to estimate even approximately the economic effects of the strike, he has given a trustworthy record and criticism of the events connected with it, and made some estimate of the place in the general labour problem of the special questions which have been raised during its course. A narrative is given of the transactions prior to the strike, of the leading events during its progress, of the issues involved and of the various negotiations for settlement, and he impartially criticises all parties concerned. He gives figures on the hours of labour which show that some of the men

Digitized by Google

COMBINED ENGINE AND DYNAMO.

CONSTRUCTED BY MESSRS. CLARKE, CHAPMAN, & CO., ELECTRICAL ENGINEERS, GATESHEAD-ON-TYNE.

GENERAL VIEW.

were kept on duty for periods altogether beyond permanent human endurance. He gives tables to show the daily percentage of instances of men on duty for 18 hours and upwards at a time, and the percentage of men, who, after having been on duty for more than 12 hours, were allowed to resume duty with less than eight hours' rest, and in both of these matters the North British Railway does not come out to advantage.

Mr. Mavor gives a very useful *résumé* of the legal questions that arose during the course of the strike, which ought to be carefully studied by all connected with trades unions, while his discussion of men and methods will be recognised as impartial. He says it is perfectly clear that, no matter what the terms may be upon which the men have capitulated, the central issue of the strike—the reduction of hours—must be faced, and that, if need be, by the raising of additional capital. He makes a suggestion which may lead to rather important results. The English Railway Servants' Society owns over £70,000, of which the sum of £24,000 is invested in 4 per cent. Debenture Stock of seven of the English lines. The sum is not a large one in proportion to the capitals of the companies; but Mr. Mavor points out that, if we consider the capital value of the men themselves, it becomes evident that they, as well as the shareholders, should be represented upon the Board of Directors. If they cannot do so as representatives of the men, they might take their places at the Board as representing the men in their capacity of shareholders, for which they might qualify themselves by investing a few thousand pounds in the ordinary stock of the company. Professor Mavor's little book will be found most useful, not only as a trustworthy record of an important labour struggle, but also as containing valuable economic criticism and information, which may be studied with advantage by capitalists and workers alike.

COMBINED ENGINE AND DYNAMO.

THE illustration given above represents a combined steam engine and dynamo constructed by Messrs. Clarke, Chapman, & Co., of Gateshead-on-Tyne, and exhibited on their stand at the Royal Naval Exhibition. The plant, which is compactly arranged, consists of an engine and dynamo coupled direct and bolted on the same bed-plate, the engine having a cylinder 8¼in. diameter with an 8in. stroke, being of sufficient power to drive a dynamo giving an output of 9,000 watts. The makers have special appliances for machining the frames and cylinders of these engines, whereby the main bearings, motion bar seatings, motion bars, cylinder, and cylinder stuffing-boxes are all bored at one setting, the cylinder flanges being also faced at the same time, thus ensuring all these surfaces being perfectly true with one another. The main bearings are of ample length and diameter, the extreme pressure being 220lb. per square inch, whilst that on the crank pins is about 450lb., and on the motion bars only 50lb., when fully loaded with a steam pressure of 120lb. per square inch. The dynamo, which is of the drum type, is constructed to give an output of 9,000 watts, or to furnish 150 16 c.p. lamps at 65 volts.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

AT a meeting of this Institution, on the 14th inst., a discussion took place on a paper entitled "Some Effects of Alternating Current Flow in Circuits having Capacity and Self-Induction," by Dr. J. A. Fleming, F.R.S.

Mr. Swinburne said he was particularly interested in the subject, for he believed he was the first to suggest the true explanation of the phenomenon known as the Ferranti effect. When the effect was first observed, it was looked upon as peculiar, and various authorities were exercised in finding an explanation. In December last, when he read a paper "On Alternate Current Condensers" before the Physical Society, no authoritative statement as to what actually occurred had been published, but he took the conditions and worked backward to see what the effect ought to be. He then found that putting a condenser on the secondary mains would increase the pressure, and explained the rise by the action of the "leading" condenser current on the magnets of the alternator. Whether the rise might be said to be due to armature reactions or to self-induction was chiefly a question as to what was meant by self-induction. He thought any rise due to the transformer would be small, but Dr. Fleming had found it fairly large. This was probably owing to the comparative smallness of the transformers used, for in very large transformers, such as he assumed were employed, the magnetic leakage to which he (Mr. Swinburne) attributed any rise caused by the transformer was relatively small.

Professor Ayrton said he took great interest in Dr. Fleming's paper, because it confirmed many results brought forward by Dr. Sumpner and himself in a paper recently read before the Physical Society. Referring to paragraph 6 of Dr. Fleming's paper, he said that the general statements about Mr. Blakesley's conclusions and those of the author was rather confusing, for Mr. Blakesley's results were only applicable to shunted condensers, whereas those of Dr. Fleming referred to unshunted condensers. On slip 4, in treating of Resonance, the author, he said, concluded that there was only a narrow range of capacity within which the pressure at

Digitized by Google

the condenser may be much greater than that at the machine. This conclusion resulted from his having chosen a coil having a resistance of only 10 ohms and a very large self-induction of 200 secohms (henries). As a matter of fact resonance effects spread over a large range, and in practice it was impossible to get a coil with such a large time-constant as Dr. Fleming had imagined. The pressure at the condenser could, therefore, never be 100 or 1,000 times that at the alternator, 5 or 10 times being about the practical limit. The experiments made by Messrs. Siemens Brothers were very interesting, and distinctly proved that the ratio of transformation of a converter varied with capacity. No doubt Mr. Swinburne would say it was all due to leakage, but nevertheless the fact that the change existed was certain. He also took the opportunity of pointing out a mistake he had made in a diagram published in *The Electrician* on January 2nd, 1891. In this figure the connections were shown wrong, and hence gave the impression that a rise occurred in the part of the circuit representing the mains themselves.

Mr. Evershed said although Mr. Swinburne had conceived the true explanation of why a rise of pressure should occur when the Ferranti trunk mains were connected to the transformers, he had not made himself clear, and his explanation was not complete, for the cause of the change in the ratio of transformation had, he said, not been given. To explain the change in the ratio of transformation, he considered a 1 to 1 transformer having considerable magnetic leakage between the two coils. When a condenser was put across the secondary mains the condenser current would be a maximum when the secondary e.m.f. was zero. But zero e.m.f. meant maximum induction in the iron, hence the condenser current being in step with the induction would increase the induction in the iron; but, owing to leakage, this increase would affect the e.m.f. of the secondary more than that of the primary, and hence change the ratio of transformation. It was therefore quite possible to neutralise the "drop" in transformers by putting on condensers, and had Mr. Ferranti designed his transformers to give a greater drop, he might have arranged so that when working on the trunk mains the "drop," instead of being converted into a rise, was exactly compensated. Referring to the method of writing equation (31) mentioned by Professor Ayrton, he protested against the terms other than R being reckoned in ohms, for passing currents through ohms meant generation of heat, whereas no self-induction wasted energy. In his opinion the terms were of the nature of e.m.f., and ought to be called e.m.f. rather than resistances.

Mr. Addenbrooke said the soaking in of the charge might affect the capacity in a way similar to that in which the insulation resistance of a cable varied with the time the current was kept on. In giving the insulation resistance of any specimen it should be distinctly stated under what conditions the tests were made. Moreover, the resistance of a cable increased for a long time after it was manufactured, and almost any desired insulation resistance could be obtained by waiting long enough.

Mr. Preece, replying to Professor Ayrton's statement that a coil having a time-constant of 20 seconds could not be made, pointed out that Faraday's coil at the Royal Institution required two minutes for the current to attain its maximum value. A submarine cable when coiled in its tank had also an enormous self-induction, as was proved by a test made by Mr. Edison at the Telegraph Construction and Maintenance Company's works, when he found that a telegraphic "dot" put in at one end of the cable came out 27in. long at the other.

THE PHYSICAL SOCIETY.

This Society varied its ordinary procedure as regards the place of meeting by paying a visit on the 9th inst. to Cambridge. Assembling at Liverpool Street Station, members and visitors to the number of about 100 were conveyed in saloon carriages direct to their destination, the whole journey being accomplished in about seventy-five minutes.

At 2.30 p.m. a meeting of the Society was held in the lecture-room of the Cavendish Laboratory. The papers read were all by authors resident in Cambridge. After the meeting the visitors inspected the Cavendish Laboratory. Amongst the many interesting instruments and apparatus to be seen, specially noticeable were Professor J. J. Thomson's 50ft. vacuum tube, glowing from end to end with a luminous discharge; Mr. Shaw's pneumatic bridge, by which the pneumatic resistance or conductivity of various shaped orifices and channels can be compared; and the new air condensers to be used by Mr. Glazebrook as standards. The Cambridge Scientific Instrument Company had an interesting exhibit, including a dividing engine, Boy's radio-micrometer, electrically driven tuning-forks, and various recording instruments, amongst which was Galton's apparatus for registering the growth of plants. Other things which attracted attention were Glazebrook's spectrophotometer; Lord Rayleigh's coils and apparatus used in his determination of the ohm; a collection of models, medals, and instruments formerly belonging to Professor Maxwell; the resistance standards of the British Association, together with the historic rotating coils and electrodynamometer used in the determination of the B.A. unit.

At the science meeting, held in the Cavendish Laboratory, Professor Ayrton, F.R.S., being in the chair, the following communications were made. The first paper was on "Some Experiments on the Electric Discharge in Vacuum Tubes," by Professor J. J. Thomson. The phenomena of vacuum discharges were, he said, greatly simplified when their path was wholly gaseous, the complication of the dark space surrounding the negative electrode and the stratifications so commonly observed in ordinary vacuum tubes being absent. To produce discharges in tubes devoid of electrodes was, however, not easy to accomplish, for the only available means of producing an electromotive force in the discharge circuit was by electromagnetic induction. Ordinary methods of producing variable induction were valueless, and recourse was had to the oscillatory discharge of a Leyden jar, which combines the two essentials of a current whose maximum value is enormous and whose rapidity of alternation is immensely great. The discharge circuits, which may take the shape of bulbs or of tubes bent in the form of coils, were placed in close proximity to glass tubes filled with mercury, which formed the path of the oscillatory discharge. The parts thus corresponded to the windings of an induction coil, the vacuum tubes being the secondary and the tubes filled with mercury the primary. In such an apparatus the Leyden jar need not be large, and neither primary or secondary need have many turns, for this would increase the self-induction of the former and lengthen the discharge path in the latter. Increasing the self-induction of the primary reduces the e.m.f. induced in the secondary, whilst lengthening the secondary does not increase the e.m.f. per unit length. Two or three turns in each were found to be quiet sufficient, and on discharging the Leyden jar between two highly-polished knobs in the primary circuit a plain uniform band of light was seen to pass round the secondary. An exhausted bulb, containing traces of oxygen, was placed within a primary spiral of three turns, and on passing the jar discharge a circle of light was seen within the bulb in close proximity to the primary circuit, accompanied by a purplish glow which lasted for a second or more. On heating the bulb, the duration of the glow was greatly diminished, and it could be instantly extinguished by the presence of an electromagnet. Another exhausted bulb, surrounded by a primary spiral, was contained in a bell jar, and when the pressure of air in the jar was about that of the atmosphere, the secondary discharge occurred in the bulb as is ordinarily the case. On exhausting the jar, however, the luminous discharge grew fainter, and a point was reached at which no secondary discharge was visible. Further exhaustion of the jar caused the secondary discharge to appear outside the bulb. The fact of obtaining no luminous discharge either in the bulb or jar, the author could only explain on two suppositions—viz., that under the conditions then existing the specific inductive capacity of the gas was very great, or that a discharge could pass without being luminous. The author had also observed that the conductivity of a vacuum tube without electrodes increased as the pressure diminished until a certain point was reached, and afterwards diminished again, thus showing that the high resistance of a nearly perfect vacuum is in no way due to the presence of the electrodes. One peculiarity of the discharges was their local nature, the rings of light being much more sharply defined than was to be expected. They were also found to be most easily produced when the chain of molecules in the discharge were all of the same kind. For example, a discharge could be easily sent through a tube many feet long, but the introduction of a small pellet of mercury in the tube stopped the discharge, although the conductivity of the mercury was much greater than that of the vacuum. In some cases he had noticed that a very fine wire placed within a tube on the side remote from the primary circuit would prevent a luminous discharge in that tube.

Following Professor Thomson's paper was one on "Some Experiments on the Velocities of the Ions," by Mr. W. C. D. Whetham. In studying electrolysis, the question as to whether there is any transference of solvent when a porous wall is absent presented itself to the author. The ordinary methods of testing for transference, such as by increase of pressure, or by overflow, not being available, when there is no diaphragm, the author used different coloured solutions of the same salt, such as cobalt chloride in water and in alcohol, the former of which is red and the latter blue. By putting the solutions into a kind of U-shaped tube, any change in the position of the line of junction of the two liquids could be measured. Two aqueous solutions in which the anion was the same were also tried, one combination being cupric chloride and common salt, and in this case the line of demarcation traversed about 7in. in three hours. The results hitherto obtained by this method agreed fairly with those found by Kohlrausch.

A paper "On the Resistance of some Mercury Standards" was afterwards read by Mr. R. T. Glazebrook. In 1885 M. Benoit, of Paris, supplied the author with three mercury standards nominally representing the Paris Congress ohm, now commonly known as the Legal ohm. Tests of these standards were described in a paper read before the Physical Society in 1885 by the present author. Recently he had occasion to compare two of the standards with the British Association coils. The mean of many concordant results gave the resistance of one of the mercury standards (No. 37) as 1·01106 B.A.U., whilst that of the other (No. 39) was 1·01032 B.A.U. Expressing them in legal ohms the present resistances are (No. 37) ·99986 and (No. 39) ·99913, whilst in 1885 the values obtained were (No. 37) ·99990 and (No. 39) ·99917. This shows that within the limits of experimental error the ratios of the mercury standards to the B.A. coils have remained practically unchanged during six years. The numbers given above are based on Lord Rayleigh's determination of the specific resistance of mercury, which differs appreciably from that found by Mascart and other observers. Taking the mean of the later concordant determinations, the values of the mercury standards expressed in legal ohms become (No. 37) 1·00033 and (No. 39) ·99959. The values given by the maker were 1·00045 and ·99954 respectively, showing a very close agreement. The author also found that refilling No. 37 from the same sample of mercury produced no appreciable change in its resistance, whilst No. 39 was somewhat affected by a similar operation. Experiments on the coefficient of increase of resistance of mercury with temperature gave the value ·000872 as the mean coefficient between 0° and 10° C., a number rather less than that obtained by Kohlrausch.

Following this, a paper, "On an Apparatus for Measuring the Compressibility of Liquids," by Mr. S. Skinner, was read. The apparatus described consists of a large spherical flask, with a long narrow neck, containing the liquid to be experimented upon, the lower part of which was in communication through a stopcock and flexible tube with an adjustable reservoir. By raising or lowering the latter the flask could be easily filled or emptied or the quantity of liquid adjusted. The flask was enclosed in a bell jar, whose interior was in communication with a pump and barometer gauge. So sensitive was the arrangement that the compression of water produced by blowing into the jar caused the liquid to descend about 1 centimetre in the neck of the flask. This movement corresponded with a change of volume of about half-a-millionth. The coefficient of compressibility has been tested at different temperatures, and the results were not very different to those obtained by Tait and others. The influence of salts in solution in changing the compressibility had also been tested, and a great difference in this respect found between electrolytes and non-electrolytes.

"Some Measurements with the Pneumatic Bridge" was the title of a paper read by Mr. W. N. Shaw. The action of the apparatus is analogous in many respects to the Wheatstone's bridge, and its object is to compare the pneumatic resistances of various orifices,. We described it specially on page 485. The proportional arms are represented by two circular holes in thin plates of mica, the third arm by an aperture provided with a sliding shutter adjustable by a screw, and the fourth might consist of any aperture or tube whose conductivity was to be determined. The several apertures are pneumatically connected by large wooden boxes. The battery takes the form of a Bunsen burner, with a long chimney, whilst the galvanometer is represented by a glass tube connecting opposite chambers and containing a vane, which sets itself at right angles to the tube when no air current is passing. The apparatus is remarkably sensitive to movements of the shutter, and on starting or stopping the draught after balance had been obtained, effects analogous to those produced by self-induction are observed. By its use it has been found that bevelling off one side of a hole in a thin plate increases the pneumatic conductivity of the aperture very considerably, particularly when the bevel is on the egress side. Another interesting result is that for square-ended tubes of given size the conductivity first increases as the length is made greater, and afterwards diminishes with further increase of length. Putting a flange on the outlet end reduces the anomalous effect, whilst a bevelled mouthpiece similarly placed causes it to disappear.

In the discussion on Professor Thomson's paper, Professor Fitzgerald said the beautiful experiments were likely to lead to very important results. He did not quite understand how placing a fine wire in a vacuum tube could prevent the luminous discharge, for if the

Digitized by Google

wire was on the side remote from the primary, and if there was any great increase in specific inductive capacity, he would have expected the air to screen the wire.

Professor Lodge asked for further information as to the action of the magnet in preventing the after-glow, and in some cases precipitating a luminous discharge. The experiment with the exhausted bulb within the bell jar was also difficult to understand, and he did not see why one of Professor Thomson's two suppositions must necessarily be true.

The President inquired whether Professor Thomson had tried Mr. Crookes' experiment, in which the electric pressure necessary to produce a discharge was greatly lessened by putting a phosphorescent material in the tube.

Professor Thomson, in reply, said he had not tried the experiment, but the phosphorescence he had observed was of quite a different character to that produced in Mr. Crookes' tubes. To Professor Fitzgerald he said the action of the wire was probably a question of time, and thought the whole field was in some way thrown on the wire, and thus discharged. In reply to Professor Lodge, he had not ascertained the true nature of the effect of a magnet on the glow, but he believed the glow to be due to a combination which might be prevented or facilitated by the action of the magnet causing the density to be different in different parts of the bulb.

M. Guillaume, in discussing Mr. Skinner's paper, described the methods used by Sabine, Taurin, and others in determining the compressibility of liquids, and pointed out their defects. The chief difficulty in such experiments was in finding the compressibility of the reservoir. Numbers expressing the compressibility of mercury obtained by different observers were given, the best values varying between ·0000039 and ·0000040.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

IX.

(*Continued from page* 475.)

Soap Powders.—Soap powders, or dry soaps, are usually intended as scouring agents, or for use with hard water, and consist largely of carbonate of soda, together with more or less real soap, and often a considerable proportion of water.

The method of manufacture is usually to melt scraps and clippings of ordinary pale soap, and to boil with soda crystals dissolved in their own water of crystallisation. When sufficiently boiled down or evaporated, the mass is run out of the pan into a trough or cooler, and a quantity of soda ash and bicarbonate of soda crutched into it while cooling, after which it is allowed to set into a stiff paste, and is then spread out to dry, either spontaneously in the air or by steam heat. The dried material is then ground in a mill to a fine powder or flour, and packed for sale, the packets being filled and lightly pressed in a hard wood or metal mould to give them the square form. The quality of dry soaps varies enormously, the proportion of water in a number of samples I have examined ranging from 25 per cent. to 60 per cent., and the amount of real soap from 18 per cent. down to 1·5 per cent., the remainder being principally carbonate of soda.

Toilet Soaps.—Under this head may be classed all medicated and fancy soaps, intended and sold specially for toilet use. They vary in quality to as great, or even greater, extent than do ordinary household soaps, and too much care can hardly be exercised in the choice of a soap, the use of which may possibly have an injurious effect on the skin, and therefore on the general health. A large number of so-called "toilet" soaps contain an objectionable amount of free caustic and carbonated alkali, which renders the skin harsh, dry, and liable to become "'chapped," besides injurious colouring matters, such as vermilion, arsenite of copper, &c.

The absence of free alkali is of greater importance in soaps intended for toilet use than in those intended for any other purpose, and the estimation of the amount of this substance present is, perhaps, the best single test of the value or even the adaptability of a toilet soap. Dr. Alder Wright, in his Cantor Lectures, classifies these soaps into three groups, according to the proportion of free alkali contained in them. He finds that the best toilet soaps adapted for use on a sensitive skin never contain more free alkali (carbonated) than 2·5 per cent. of the amount of alkali present in the form of soap, and he accordingly places in the first class, those soaps which are either actually neutral, or free from uncombined alkali, or else contain not more than the amount stated above. The second class includes soaps in which the free alkali exceeds 2·5 per cent., but is less than 7·5 per cent. of the total, while all soaps which contain more than this amount are placed in the third class.

In addition to the percentage of free alkali, however, certain other points are taken into consideration, in deciding the claim of a sample to be regarded as a first-class soap; such as its freedom from rankness, or rancidity of the original glycerides used in its manufacture, and its non-liability to oxidise and become discoloured on keeping. It must not be weighted nor adulterated with inert or injurious materials, and if coloured, or medicated, the colours used, and the agents added, must be of an uninjurious character, and not liable to affect the skin when the soap is used habitually. It must also produce a good lather, and be economical, emollient, and pleasant in use.

To eliminate free alkali from finished soap, Dr. Alder Wright has proposed the addition of ammonium chloride, which reacts with the uncombined alkali, forming sodium chloride and ammonia, the latter being dissipated by the heat of the liquid soap and on exposure of the cut bars to the air.

The lowest form of so-called toilet soap consists merely of ordinary fitted primrose or household soap, tinted with various colouring matters, and slightly scented with nitrobenzene, citronelle oil, and other cheap perfumes. The free caustic soda, which such soap nearly always contains, is wholly or partially neutralised by the addition of cocoanut or palm oil while being crutched; and this attempt to neutralise the free caustic alkali is, in many cases, the only claim such soaps have to be regarded as toilet soaps. Ordinary household and laundry soap is very often treated with oil in the same way to neutralise free caustic soda, and these would have as valid a claim to be ranked as toilet soaps as the cheap coloured tablets referred to, the very small extra amount of perfume added to the latter being practically of no moment. The colouring matter frequently added to this class of soap also forms an objection to its use, vermilion, red lead, and other insoluble, gritty, and poisonous mineral colours being used, instead of the more harmless organic or vegetable tinctorial substances, for the reason that the former are better able to withstand the action of light and do not readily become faded when exposed for some time.

Another and better class of toilet soap largely made in this country is prepared by remelting white curd soap in a jacketed pan, and tinting, either by crutching in colouring matter, or by the addition of a certain proportion of coloured soap, the latter method being preferable. The bars of soap to be remelted are first reduced to thin shavings, by passing them, with pressure, over an inverted plane, similar to an ordinary joiner's tool, mounted on four legs. The long, broad shavings are then placed upright in the heated pan, resting against and supported by the sides all round. This is called a "round," and it is allowed to melt down before a second round is put in, and so on until the soap is all melted. If the product is to be tinted by the addition of already coloured soap, the white and coloured shavings are put into the pan in alternate rounds. A little oil is then crutched into the melted soap, together with potassium carbonate, common salt solution, and various other substances, which are occasionally used; and, if intended for a medicated soap, a certain proportion of the active principle, such as thymol, carbolic acid, eucalyptus oil, &c., after which it is placed in a frame, where the perfumes are added and the soap allowed to cool. These soaps, after cutting into tablet pieces, are usually dried in a steam-heated stove for a short time before they are stamped and packed.

The best transparent soaps are made by what is called the alcohol process, which consists in dissolving ordinary, good, opaque soap, made from tallow, lard, and other fats and oils, in boiling alcohol, and subsequently evaporating off the solvent, leaving the soap in a more or less transparent condition. By this process any carbonate of the alkali, sulphate of soda, and other impurities present in the original soap are entirely eliminated in the finished product, as these substances are insoluble in alcohol; but, on the other hand, any free caustic alkali which it may contain is dissolved along with the soap itself. The solution of the soap, which is first reduced to shavings and dried as completely as possible, is effected in a closed vessel resembling a still, and when all the soap has dissolved the solution is placed in another still, from which the alcohol is distilled off and condensed, ready for further use, after which the residue of hot soap is withdrawn and placed in suitable frames to set. After cutting, the soap, which is usually muddy-looking and far from clear, is exposed for some time to warm air, to evaporate remaining traces of alcohol and water, during which time it becomes clear and transparent. By long keeping and exposure to air the soap also darkens in colour, acquiring a rich amber tint. The addition of glycerine materially improves the soap by giving a more transparent product, besides imparting a pleasant, emollient feel in use. Sugar and rosin also have the property of increasing the transparency, but their use is not to be recommended, because the addition of sugar also renders the product more soluble or wasteful in use, whilst soap containing rosin is apt to contain free alkali or to liberate an increased amount of that substance when the soap is dissolved in water. There are, therefore, various qualities of soap made by the alcohol process, resulting from the presence or absence of the above and other substances, and also from the substitution of methylated spirit for pure alcohol, as is sometimes the case.

A large amount of low-priced transparent soap is made, by the so-called "cold process," from castor oil, tallow, cocoanut, palm, and other oils. This soap almost invariably contains not only free carbonated, but also caustic alkali, in comparatively large quantity, some samples containing as much as 25 per cent., or even more, of excess of alkali, over that combined with the fats and existing as soap, rendering its use highly irritating to and probably likely to cause blotches or pimples on a sensitive skin. This kind of soap also consists largely of sugar—to the extent of 20 per cent. or 30 per cent.—and of water, the percentage of real soap being comparatively only small. To make the soap, the fats and oils are melted at a low temperature (180° Fahr. to 190° Fahr.) in a jacketed pan, provided with revolving crutching arms or mixers, as previously described, and the exact quantity of strong caustic soda solution of about 1·30 sp. gr., required to completely saponify the oils, is vigorously crutched in. The pan is then covered and left at rest for some time, during which the temperature rises considerably, and the saponification is supposed to be completed. A quantity of sugar, dissolved in hot water, is then stirred into the soap, and some crystals of sodium carbonate also added. Methylated spirit is then put in, to clear the liquid, and cause the fob to rise to the surface; while the pan again remains covered and at rest for some time, after which the fob is skimmed off, and the clear thin soap ladled into the frames, where the perfumes are added, and it is allowed to set. After two days it is cut into bars and tablet pieces, the latter requiring to be carefully stoved before being stamped and packed.

This kind of transparent soap is generally coloured with aniline or other colour to imitate the amber tint of the better-class soaps, and, although it is sold at a low price, it is so wasteful in use, dissolving rapidly in the water, especially if hot, that it cannot really be regarded as being cheap, irrespective of its other objectionable points.

(*To be continued.*)

SOCIETY OF CHEMICAL INDUSTRY.

LIVERPOOL SECTION.

At the last meeting of this section a paper was read by Mr. J. H. J. Dagger on "The Manufacture and Industrial Value of Aluminium." After some reference to the history of the subject, Mr. Dagger proceeded to deal with the electrolytic processes for the preparation of aluminium. The ores that can be employed for the purpose are bauxite and corundum, for although alumina is widely distributed in other forms, these latter are too impure to be of any service in the preparation of the metal. The only other ore that comes into use in the method is the double fluoride of sodium and aluminium (cryolite), which is, however, not used as a direct source of the metal, but only as a flux. In referring to the relative values of the electrolytic and sodium processes for the preparation of aluminium, the author of the paper was of opinion that it was not possible for the latter to produce the metal in a pure state at so low a price as the former could. This price had been reduced from 15s. per lb. in 1888 to 5s. per lb., its present value, and further reduction in price was to be expected rather in improved methods for purifying the alumina than in more advantageous means for separating the aluminium therefrom. Of the electrolytic processes, both the Heroult system, as worked on the Continent, and the Hall process were described, full details of the method of working given, and the results obtained being illustrated by two blocks of the metal weighing about 3lb. each, produced by the latter process.

In conclusion, Mr. Dagger referred to the physical properties of the metal and the industrial applications for which, in his opinion, it was likely to prove of value. Aluminium is unacted on by air or moisture, sulphuretted hydrogen, ammonium sulphide, or cold dilute sulphuric acid, as long as it is pure, but if iron or silicon be present it is not proof against the above reagents. Cold nitric acid does not affect the metal, and the organic acids and their salts have practically no corrosive action. Owing to the non-poisonous nature of the salts of aluminium it would be of value for making cooking utensils, tins, and cases for preserved foods, &c. Its high specific heat and malleability would also give it important applications. Castings can be readily made with the metal in ordinary dry sand moulds, and bars of aluminium give out a clear musical sound when struck, but the presence

Digitized by Google

of even a small proportion of impurity destroys the resonance. The tensile strength of the metal is only half of that of the best wrought iron, and this would prevent its ever replacing iron or steel for structural purposes. But for light machinery, gas and water fittings, steam pipes, electrical machinery, and for all art and decorative purposes, aluminium had a great future before it, and was destined to replace some of the older metals, especially copper. Aluminium plating was also likely to supersede both tin and nickel plating, whilst the chemists' laboratory was likely to receive many welcome improvements in the form of aluminium utensils.

An interesting discussion followed, during which, in reply to various questions put, Mr. Dagger stated that the yield of aluminium obtained from the oxide amounted to 97 per cent. of the theoretical quantity; also that the difficulty of soldering aluminium had been partially overcome by employing an alloy of aluminium, copper, and zinc. Aluminium, although it only melted at 1,300°, began to soften at 600°-700° F., a fact which would prohibit its use in various chemical operations.

At the same meeting Mr. J. Hayes read a note on "An Interesting Point for Chemical Manufacturers in the New German Patent Law," in which it was pointed out that in accordance with the new German patent law, which will come into action from October next, a patent taken out will extend not only to the process patented, but also to the product produced, and the patentee will have a claim in the case of products when produced by his process and without his consent. This change from the law of 1877 will remove what has been a distinct grievance to German chemical manufacturers, especially in the case of the importation of products from countries where no patent for the production of the same has been taken out.

THE MANUFACTURE OF LACTIC ACID.

In a recent report of the meeting of the London Section of the Society of Chemical Industry (see *Industries* of the 20th March) we recorded the fact that lactic acid is being made in America on a large scale from glucose. According to Mr. C. F. Cross, lactic acid will find extensive application in the calico-printing trade, the demand that will arise as soon as its merits are known being sufficient to absorb all that can be produced for some time to come. It is therefore a matter of special interest that a sign of the reality of this demand, and of the corresponding efforts that have been made to meet it, should be afforded from a wholly independent source. Commenting on the fact that most of the processes hitherto in use have not been available for the successful manufacture of lactic acid at a cheap rate, G. Jacquemin, in the *Jour. Pharm. Chim.*, describes a method of his own, which he claims to be free from the tediousness, uncertainty, and expense previously inevitable. Completely saccharified malt is mashed in the same way as in brewing, save that the temperature is kept longer at 50° C., in order to obtain as much maltose and as little dextrin as possible. The temperature is then raised in succession to 60°, 63°, and 65° C., and finally to the boiling point, whereby a wort rich in sugar and containing sufficient albumenoids for the subsequent nutrition of the lactic ferment, but thoroughly sterilised, results. It is neutralised with calcium carbonate, and the pure ferment, prepared by Pasteur's process, added. Fermentation is carried on in vessels whose lids are provided with a water-seal. Three tubes pass through this cover. The first is a siphon for drawing off the heavy carbon dioxide which is a product of the fermentation. The second is a tube for the admission of air, filtered by passing through cotton-wool, to replace the carbon dioxide as fast as it is drawn off. The third reaches to the bottom of the vessel and ends in a rose, and is used for blowing sterilised air through to stir up the contents, a process which should be done at least twice a day. The vessel is kept at 40°-45° C. by steam coils, the fermentation being found to proceed best at that temperature, and being under these conditions completed in five to six days. The fermented liquid is drawn off, filtered, evaporated, when calcium lactate quite free from smell separates out. The separation of lactic acid from this salt is accomplished in the ordinary way.

Notes.

ENGLISH GOODS IN RUSSIA.

A recent official report states that all over Russia British goods are preferred to those of German or French make, but owing to the considerable difference in price, the excessive transport charges, and the unwillingness of the British manufacturers to alter their patterns to suit the requirements of Russia, the goods of the latter countries are rapidly ousting those originating from Great Britain. It is not so very many years since that the plough trade of Russia was monopolised by British firms, many of whom have had to give way to their German competitors.

RAILWAYS IN NEW SOUTH WALES.

At the end of last year there were 2,182 miles of railway open for traffic in New South Wales, as against 2,171 miles in 1889. There was an appreciable increase in the revenue last year, the receipts for the last quarter of the year amounting to £914,141, being an increase of £107,516 on the revenue for the last qnarter in the year 1889.

THE JAFFA AND JERUSALEM RAILWAY.

The construction of the railway between Jaffa and Jerusalem, which is in the hands of a French company, is actively progressing, and seems likely to become an accomplished fact. The company which has undertaken the construction of the railway has three years in which to complete the work, but it is expected that it will be finished fully a year before the required time, a portion being already completed. When the railway is completed pilgrims will be able to use it in their journey from Jaffa to Jerusalem.

COAL RAISING IN MICHIGAN.

There are now three leading localities in Michigan, U.S.A., where coal is mined in quantity. These are Jackson, Owosso, and Sebewaing, the latter of which promises to become the most important, although the largest establishment at present is that of the Standard Mining Company, located one mile from Jackson. The coal bed at this point varies from 3ft. to 4ft. in thickness. The quality of the Sebewaing coal is, states the *American Manufacturer*, much better than the product of the Jackson County mines. The coalfield of Michigan is detached from that of any other State.

FIRE-BRICK MANUFACTURE IN RUSSIA.

In the vicinity of Adjikent, in the government of Elizavetopol, a kind of refractory clay has been discovered of the quality required for preparing fire-bricks. Mr. Levin, a Swede, has availed himself of the discovery, and has established works at Baku for manufacturing fire-bricks. The output of those works amounted in 1890 to about 450,000 bricks. This industry, which it is intended to extend, is likely to oust from the local markets the fire-bricks now coming from Glasgow.

MEASURING ELECTRICAL POWER.

There will probably be an interesting meeting of the Physical Society this week, and perhaps a lively discussion on the methods of measuring electrical power in alternating circuits. Dr. Fleming has recently made the three-voltmeter method more practical by using three ampere meters in an analogous manner. It is questionable whether any of these methods are so good as an electrostatic or an electromagnetic wattmeter. Unfortunately some persons have a prejudice against wattmeters. It has however, little foundation, as a reasonably well-designed wattmeter is accurate within errors of observation.

METALLURGICAL PROGRESS IN LEEDS

To the various metallurgical processes carried on in Leeds we must now add those connected with copper smelting. For many years past cupreous iron pyrites have been burnt at vitriol works in the town, the burnt pyrites being sent away to copper works for further treatment. Messrs. John Nicholson & Sons, of the Church Street Chemical Works, Hunslet, Leeds, who are large burners of pyrites, erected works about four years ago for the treatment of the cinders by the wet extraction method silver and gold being recovered by the Claudet process, the copper precipitate obtained being sold to Liverpool, Swansea, or German copper smelters, the residual oxide of iron —"purple ore" or "blue billy"—being used in puddling or in the local blast furnaces, while the waste liquors, which contain sulphates and chlorides of iron and sodium, play a somewhat important part in the clarification of the sewage of the town, the iron salts taking the place of the sulphate of alumina generally used in precipitation processes. The conversion of copper precipitate into ingot copper being a comparatively simple operation, and as a considerable quantity of copper is used locally, Messrs. Nicholson have recently erected furnaces for its treatment. The precipitate, mixed with a small proportion of coal or other reducing agent, is first treated in a roaster furnace, when "blister" copper is formed, together with some slag. The blister copper is afterwards refined—*i.e.*, the impurities are removed by oxidation—and after skimming off the slag the excess of oxide is removed by poling in the usual manner, and when the copper has attained the necessary degree of toughness and ductility it is made into ingots or cakes of commercial copper, while the resulting slags are practically freed from the copper they contain by fusion with sulphide ores in another furnace.

MINING IN ALGERIA.

The district of Bougie is rich in mineral deposits, though but few of them are actually worked. One English company possesses mines at Tadergount and Karrata, yielding argentiferous grey copper ore, which is said to contain as much as 35 per cent. of copper and 100oz. of silver per ton. The deposit of red hematite at Dybel Animi is very important, but it cannot be worked until a railway between Bougie and Setif—which would pass close to the mines, and which is at present under consideration —is constructed. Amongst other deposits at present unworked are the lead mines of Cavallo, the argentiferous grey copper mine of Tellionine, and numerous other deposits of lead, copper pyrites, sulphide of antimony, calamine, manganese, iron, &c. Some of these have already been worked, mainly by English capital, but on account of the want of economical means of transport have been suspended.

A LARGE ELECTRIC MINING PLANT.

The Cœur d'Alene Silver-Lead Mining Company have, states the *New York Electrical Engineer*, contracted with the Edison General Electric Company for an electric power transmission plant, which, when completed, will probably be the largest in the world, to operate all the machinery and furnish light for their mill and mine at Burke, Idaho. The plant consists of two 225 h.p. Edison generators, to be located about a mile and a half from the mill, and driven by water power from the falls of Canyon Creek, using Pelton wheels under about 690ft. head. The mill machinery will be driven by an 80 h.p. motor belted direct to the main shaft of the mill. The Ingersoll steam drill compressor now in use will be operated by a 60 h.p. motor driven from the fly wheels of the compressor. The Lidgerwood steam hoist now being used will be operated by a 50 h.p. motor geared direct to the present driving shaft. The pump, located on the 500-foot level, will be driven by an 80 h.p. motor geared direct. The entire plant is at present being operated by steam, and the application of electricity will be so arranged that all the machinery, or any portion of it, can be operated by either steam or electric power at any time.

THE JABLOCHKOFF PATENT.

Another venerable patent has joined the majority. An attempt was made to galvanise it into life again, but its existence could not be prolonged beyond its allotted days. Little was known of this patent until recently, when it was suddenly brought forward to cover transformer distribution. The owners did not attempt to deal harshly with the public, and their moderation secured royalties instead of opposition. While the loss of the patent may be regretted from the owners' point of view, it may be as well to mention that Jablochkoff did not invent transformer distribution. Though his claim may have covered it, it was a mere accident. His object was not to transform from a high to a low pressure, nor to save copper in leads; but to allow a number of lamps to be run off one machine, or, in the words of those days, to "subdivide the electric light." He thought that by putting the lamps on secondary circuits of transformers in series, they might go out accidentally without destroying the continuity of the dynamo circuit. His transformer was specially designed to be short-circuited completely. He makes a merit of having the copper in metallic contact with the iron of the core throughout. We merely mention this as one of the too common cases where the merits of an invention are taken away from the real inventor and given to some earlier worker who has unintelligently stumbled on something like it, without in the least understanding its capabilities.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

4th May, 1891.

7668. Gilmer, W. F. ..... Coupling for railway carriages.
7669. Anderson, J. ..... Water-raising apparatus.
7680. Powell & Williams..... Dusting and polishing tin or terne plates.
7683. Thistlethwaite, J. ..... Footsteps for small spindles.
7689. Lentz, G. ..... Steam boilers.
7693. Jones, J. ..... Roller grinding mills.
7704. Burgess & Davis ..... Vacuum evaporating apparatus.
7708. Legrand, G. J. J. ..... Supplying air to furnaces.
7709. Edwards, E. ..... Attaching the picking strap to the picking stick in looms (*Held*).
7711. Hollingworth, E. ..... Jacquard mechanism of looms.

5th May, 1891.

7718. Mays, J. A. ..... Amalgamating apparatus.
7721. Dixon, G. ..... Steam boilers.
7724. Suiter, A. ..... Pressure gauges.
7725. Suiter, A. ..... Fittings for compressed gas vessels.
7726. Mole, F. M..... Bronzing machines.
7729. Hatfield, J. ..... Coupling mechanism for railway cars.
7730. Crowe & Allan..... Liquid fuel furnaces.
7734. Hunting, A. A. ..... Apparatus for treating leather.
7746. Parker, J. J. ..... Spring frame for safety bicycles.
7747. McCarter & Cooper..... Motive power engines.
7748. Moore, E. J. ..... Steam boilers.
7750. Davis, G. ..... Steam engines.
7751. Bolthoff, H. ..... Steam engines and valve gear.
7752. Egge, F. ..... Machine for automatically manufacturing sheet metal chains.
7758. Lake, H. H..... Vacuum pumps (*Nye*).
7766. Whittall, J. ..... Pumping apparatus (*Kinder*).
7767. Farjasse, M. H. C. W.... Brake apparatus for stopping and starting vehicles.
7768. Crossley & Holt ..... Oil motor engines.
7779. Stracey, G. H. C..... Apparatus for facilitating the ascent of engines or trains up steep gradients.
7789. Jenkins, T..... Apparatus for cleaning tin and terne plates.

6th May, 1891.

7815. Potts, S. ..... Endless conveyers.
7816. Baird, M. B. ..... Steam generating apparatus for ventilating purposes.
7818. Black & Fleming ..... Fans for ventilating mines.
7819. Dyson, A. E. ..... Screw-down cocks.
7827. Timmis, I. A. ..... Railway signalling.
7849. Millar, J. S. ..... Valves and ports of steam engines.

7th May, 1891.

7856. Stokes & Stokes ..... Machine for making nuts for screw bolts.
7859. Fitzpatrick, H. D. ..... Machine for cleaning roads (*Hentschel*).
7866. Newall, J. W. ..... Cutting the teeth of bevel wheels.
7867. Thompson, W. P. ..... Evaporating apparatus (*Wirth & Co.*).
7868. Ingham & Derbyshire... Machines for cutting screw threads.
7872. Malloch, J. M. ..... Stop valve.
7875. Penney, C. ..... Passenger communication for railway trains.
7879. Bailey, W. H..... Machinery for winding and twisting yarns.
7884. Hindle, Hindle, & Isherwood..... Mechanism for operating shuttle guards of looms.
7898. Moores, W. ..... Combing machines.
7914. Ashlin, H. C. ..... The construction of vessels.

8th May, 1891.

7928. Murray, A..... Portable drilling, tapping, and studding apparatus.
7945. Hutchinson, W. S. ..... Water-gas furnaces.
7946. Allison, H. J. ..... Tool posts (*Ronan*).
7948. Greenwood, H. ..... Machinery for compressing gunpowder into pellets.

9th May, 1891.

7982. McAnelly, J..... Lubricators.
7992. Liversidge, W. G. ..... Feed motion of drills.
8000. Munns, W. H..... Car coupling (*Schatz*).
8007. Price, J. T..... Paper folding machines.
8014. Thompson, W. P. ..... Steam boilers (*Binder*).
8016. Saxby, J. ..... Interlocking apparatus for railway point and signal levers.
8026. Seitz, E. ..... Centrifugal pump.
8032. Horn, W. W. ..... Gas engine (*Vanduzen & Vanduzen*).

ELECTRICITY.

4th May, 1891.

7667. Callendar, H. L. ..... Dynamo-electric machines.
7688. Saunders, A. ..... Spiral filament for incandescent lamps.
7697. Elmson, C. P..... Accumulators.
7700. Allison, H. J. ..... Storage battery plates (*Kennedy & Diss*).

5th May, 1891.

7715. Washburn, G. A. ..... Storage batteries.
7755. Lake, H. H..... Dynamo machines (*The Crocker Wheeler Electric Motor Company*).
7762. Van Depoele, C. J. ..... Reciprocating electric engines.
7778. Thompson, W. P. ..... Conductors (*Williams*).
7781. Boucherot, P. ..... Means for converting electric currents.
7782. Wallaston & Mudford Induction apparatus.

6th May, 1891.

7822. Giraud, P. ..... Thermo-electric stove.
7831. Reynier, H. ..... Insulating partitions for batteries.
7850. Horn, W. W. ..... Automatic telephone exchanges (*Strowger*).

7th May, 1891.

7857. Bryan & Woodhouse & Rawson United, Ld. Construction of rheostats.
7858. Snell & Woodhouse & Rawson United, Ld. Switches.
7878. Rowan & McWhirter ... Appliance for preventing ignition of gases in connection with dynamos, &c.
7911. Grimston, G. S..... Switch.
7912. Grimston, G. S..... Electric capstan.

8th May, 1891.

7937. Cox, C. W. ..... Resistance devices.
7949. Goward, P..... Secondary batteries.
7960. Sanders, R. D. ..... Manufacture of metal tubes by electro-deposition.
7970. Wahlström, E. A. ..... Distributing electric energy.

9th May, 1891.

7976. Binswanger, G. ..... Handles for light switches.
7979. Pritchett, G. E. B. ..... Accumulators.
8031. Howard, H..... Apparatus for heating and welding by the electric arc.
8034. Shepard, A. L..... Device for facilitating the connection and disconnection of electrical conductors.

CHEMISTRY.

4th May, 1891.

7692. Fischesser, J..... Azo-colouring matters.
7713. Johnson, J. Y. ..... Production of new diazo dyes (*Badische Anilin & Soda Fabrik*).

5th May, 1891.

7756. Eberhardt, M. ..... Compound for extinguishing fires.
7757. Fish, C. H. ..... Furnaces for burning sulphur.

6th May, 1891.

7803. Lembach, Schleicher, & Wolf ..... Manufacture of ortho-oxyquinoline.

8th May, 1891.

7963. Imray, O. ..... Manufacture of nitro-and amido-methyl-phenylpyrazolon (*Die Farbwerke vormals Meister, Lucius & Brüning*).
7964. Imray, O. ..... Blue colouring matters (*Die Farbwerke vormals Meister, Lucius & Brüning*).

9th May, 1891.

8006. Martin, E. L. C. ..... Manufacture of caustic soda and caustic potash.
8018. Lunge & Dewar ..... Recovery of sulphur, carbonate of soda, and iron oxide from double sulphide of sodium and iron.
8022. Honman & Vullier ..... Process of manufacture of white lead.

MISCELLANEOUS.

4th May, 1891.

7673. Morison, W. C. ..... The reduction of ores.
7676. Campion, A. J. ..... Hard metals.
7712. Varney & Hiratt ..... Railway rails.

5th May, 1891.

7719. Melling, J. ..... Joint for pipes.
7723. Nelson, E. ..... Washer.
7727. Platt & Platt ..... Die for making dividable tiles.
7735. Whitehill, W. ..... Automatic measuring taps.
7736. Jones, G. P. ..... Safety catch for hoist cages.
7775. Wood & Milner's Safe Company, Ld. ..... Safes.
7777. Thompson, W. P. ..... Cooling certain metals (*Clamer*)
7787. Hammond & Gordon ... Railroad spike.

6th May, 1891.

7823. Tofts, G..... Inking roller for printing machines.
7824. Skaife, W. ..... Galvanising metals.

7th May, 1891.

7855. Barron, E. R..... Guards for belts.
7871. Sharne, A. ..... Automatic signalling to trains.
7916. Tabrar, J. ..... Nuts, washers, and bolts.

8th May, 1891.

7919. Hutton & Daniels ..... Ratchet braces.
7924. Oakes, Leigh, & Mellor Picking band for looms.
7981. Smith, F. W. ..... Typewriting machines for the blind.
7982. Dawson, S. ..... Guard to weaving shuttle.
7988. Keith, T. de W. ..... Wrenches.
7952. Hall & Storm ..... Wrenches.
7974. Vibert & Rowland ..... Preventing incrustation in boilers.
7975. Schluss, F. O. C. M..... Fastening devices for securing rails to sleepers.

9th May, 1891.

7986. Holt, M. ..... Pickers.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

6788. Macey & Cummings.
7082. Boult (*Lachaume & Pasteyer*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Stop Cocks and Valves.—*W. H. Spencer & J. M. Ralston, Hitchin.*—These improvements relate to full-way valves in which the valve proper is formed of two separate discs, which are pressed outwards against their seats when the passage is being closed as the valve approaches the end of its travel. The

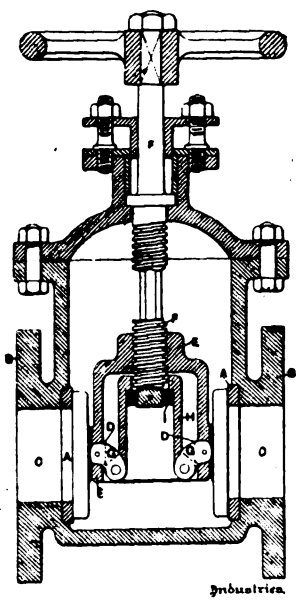

illustration herewith shows in vertical section a full-way stop valve in the closed position, A A being the faces or seats on which two valves B slide for the purposes of closing the passages C. On the backs of the valves are two projections D fitting into suitable apertures in a hollow box E, which is raised and lowered by the actuating screw F, which has no motion in the direction of its length. Fitted between the projections F and fixed to them by a pin are links G, which are also attached to the sleeve H, and at the bottom of the actuating screw F is a collar I, screwed on, and adjustable as may be necessary. Guides to prevent the valve from taking up a wrong position on its seats are provided on the sides of the valve casing, into which grooves fit projections (not seen in the illustration) on the box E. As the valve approaches the end of its travel the sleeve H at a certain point is prevented from descending further by the collar I, while the box E is forced downwards by the screw F, and, carrying the valves B and links G with it, causes the links to press the valves against their faces and close the passage. By means of the collar I the valves can be adjusted to close at any desired point. Claims: The arrangement substantially as described.—No. 3033. February 19th, 1891. 6*d*.

Railway Brakes.—*E. Hartmann, Düsseldorf, Germany.*—This inventor desires to enable railway vehicles having brakes of any known kind to be employed in trains together with vehicles having brake apparatus worked either by compressed air or by vacuum. For this purpose such first-named vehicles are provided with an additional conduit pipe, having at each end of the vehicle flexible extensions with coupling devices for coupling with the air pressure or vacuum pipes of adjoining vehicles. Each of these special pipes are connected to both ends of a cylinder, adapted for use either as a double-acting air or vacuum cylinder, and capable of operating various types of brakes in a manner

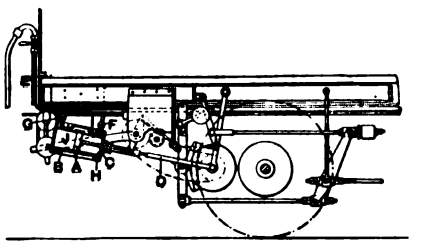

FIG. 1

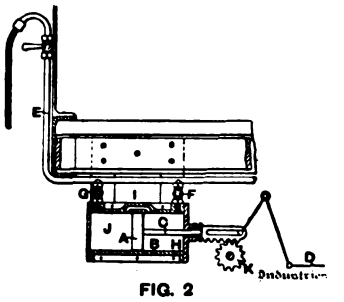

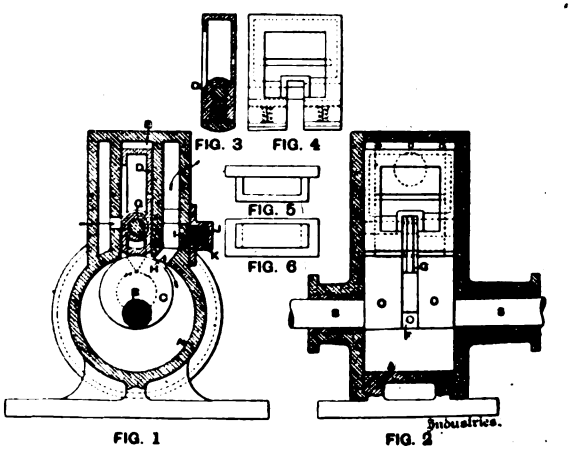

FIG. 2

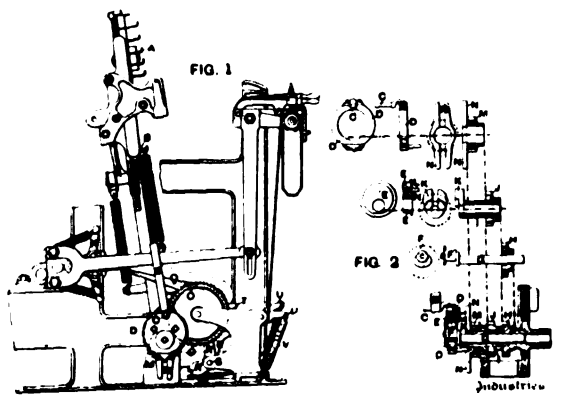
presently to be explained. Fig. 1 shows the application of the apparatus to the working of a chain brake; in this illustration the piston A of the special brake cylinder B is connected by a slotted rod C to the rod D of the brake friction-drum in such a manner that operation of the latter in the ordinary manner by its own gear is not interfered with. The cylinder B is connected at each end to the train pipe E by branch pipes provided with cocks F G. For operating the chain brake by air pressure air is admitted at F; the piston is then moved back from the front end H of the cylinder until the channel I is uncovered thereby, whereupon the air passes through I to the opposite side of the piston, which is then in equilibrium. To apply the brake, air (as in the Westinghouse automatic brake, for example) is discharged from the train pipe E, and the air pressure in the space J behind the piston causes a rapid movement of the piston from J towards H because of the diminution of pressure in H, the passage I being too small to prevent any material escape of air from J to H during the brief interval that elapses before the piston, in its movement, closes that passage, and thus keeps the brakes applied until a recharging of the train pipe reproduces the operation at first described. To operate this mechanism by vacuum the cock F is closed and that at G is opened, and the whole of the interior of the cylinder is exhausted; an admission of air to the vacuum pipe to apply the ordinary vacuum brake apparatus produces, as in the previous example, a difference of pressure in the ends H and J of the cylinder, the pressure in J being superior, as before, although probably less in degree. The resulting operation of the brake is similar to that already described, and either operation would be automatic in the event of a breaking apart of the train. The piston rod of the special cylinder B may be operated by hand gear to apply a brake, the hand gear operating a pinion K gearing into a rack on the piston rod, as shown in Fig. 2. Other arrangements for hand-brake working are described, in which slotted connections and other arrangements for permitting the independent working of the brakes by hand and by power are comprised, and it will be evident that the application of non-automatic air and non-automatic vacuum working to the piston A is easily arranged by opening cock G in the former case and cock F in the latter. Claims: An air pressure or vacuum brake apparatus consisting of a cylinder with a bye-pass passage, and fitted with valves such as F and G, the parts being arranged and operated as described, whereby a carriage with such brake apparatus can be coupled to and be operated in conjunction with other carriages having either the same or a different kind of brake apparatus.—No. 8079. May 23rd, 1890. 8*d*.

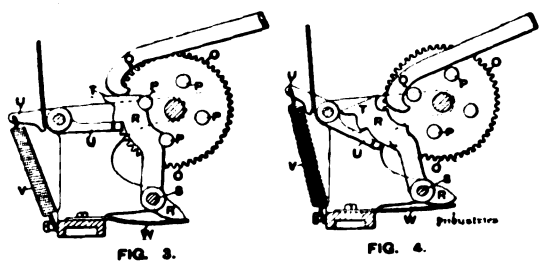
Water Gas.—*J. Blum, Berlin, Germany.*—The inventor produces water gas by the chemical reaction between crude petroleum or other hydrocarbon, and heated nickel, cobalt, or copper. He considers it essential that the water and petroleum should be intimately mixed, that the quantities in the mixture should be very nearly in the chemical proportions requisite for mutual decomposition, and that the temperatures of the metals should be, for nickel, not less than 570° Fahr., for cobalt, not less than 630° Fahr., and for copper, not less than 850° Fahr. A water-gas generator, in which these conditions may be obtained, is described, and consists of a seamless steel or copper tube having flanges at both ends to which lids are screwed or bolted. Through the upper lid passes an injecting tube, and through the lower lid a tube through which the generated gases find egress. Two-thirds of the generator, from the bottom upwards, are filled with a net work of nickel, cobalt, or copper wire, or of copper wire plated with nickel or cobalt; pieces of these metals or fireclay plated therewith may be substituted. Surrounding the generator is the furnace, in which burn gas flames for heating the exterior of the generator, and above the furnace and the generator is a circular tank of iron with an inner compartment of the same material, the two compartments communicating by openings, one at the top of the inner tank and another at the bottom; a single tube places both these compartments in communication with the generator. The outer compartment is for water, the inner one for petroleum, and the areas of the two bear the same ratio to one another as do the quantities of water and petroleum necessary for mutual decomposition. In practice the ratios of area are made as 4:1, but the sectional area may be reduced to satisfy chemical requirements by the insertion of vertical heating tubes in the outer tank. A valve controlling communication between the tanks and the generator is connected by a rod to the safety valve; thus, when the tanks are filled with water and petroleum, the whole being heated, vapour is formed, which presently becomes of sufficient pressure to lift the communicating valve, and the fluids are dispersed through a perforated tube on to the heated metallic contents of the generator, becoming instantaneously decomposed and converted into water gas, which can be generated at any pressure permitted by the strength of the material of the generator. It may be used as a motive fluid in an ordinary engine, and afterwards be returned to the furnace and burnt. Claims: The process of obtaining water gas by the decomposition of water by means of a hydrocarbon in the presence of a heated metallic body; the use of a generator charged with nickel, cobalt, or copper as described; the tank, by means of which liquids in regulated quantities and correct proportions are caused to enter the generator.—No. 5289. April 5th, 1890. 8*d*.

Rotary Engine.—*G. D. Davis, Poplar, London.*—This invention has reference to improvements in rotary engines especially designed for use with steam as the motive fluid, but they may be adapted for use with air, water, or gas. In carrying out the invention a cylinder is employed, through the centre of which passes a shaft, lying in the axis of the cylinder and carried in suitable bearings formed in the ends thereof. On this shaft is eccentrically mounted a cylindrical piston, which works in contact with the cylinder at a peripheral line, and along this line of contact is a renewable piece fitted into a groove in the piston, to make a steam-tight joint between it and the cylinder. In a circumferential groove at the middle of the piston's length is a strap operating a sliding abutment, the lower end of which bears upon the periphery of the piston, the said abutment forming also a valve, which is balanced by the admission of steam to both its faces, and which is reciprocated by the piston in a chamber formed in one with the cylinder above referred to. In the illustrations below Fig. 1 is a vertical section of one modification of the engine, Fig. 2 a sectional view of the same at right angles to Fig. 1; Fig. 3 is a sectional view of the sliding valve or abutment, shown as having its lower part fitted with springs to keep it up to its work, the said lower part being renewable, Fig. 4 being an external view of Fig. 3, and Figs. 5 and 6 being respectively a plan and side view of the renewable piece. A is the cylinder, B the main shaft, C the piston, D the sliding valve and abutment, E the valve chamber, F the strap or ring driving the valve D by the link G. Steam being supplied to the interior of the valve D as shown by the arrow, and thence to the interior of the cylinder A (into an increasing space which, when the engine



moves from its present position, will be enclosed by the abutment, part of the periphery of the piston, and part of the end and interior surfaces of the cylinder) the piston will rotate, and the steam will ultimately exhaust by the port H. Part I of the wall of the valve chamber is made moveable in grooves, and is kept to its work against the lower face of the valve by means of a spring J contained in the removable chamber K provided for it. For convenience of construction the eccentric strap and rod may be formed in two parts, so as to be applied on opposite sides of the main shaft, and held together by pins at the lower end, and by the gudgeon in the valve at the upper end. Another modification conforming to the same general principle, but having details slightly different, is described, and the inventor claims: In a rotatory engine, a rotating piston, a cylinder therefor, in combination with a sliding reciprocating abutment and valve operated by the piston, and the rest of the details of the arrangement, as described in the specification.—No. 7807. May 20th, 1890. 8*d*.

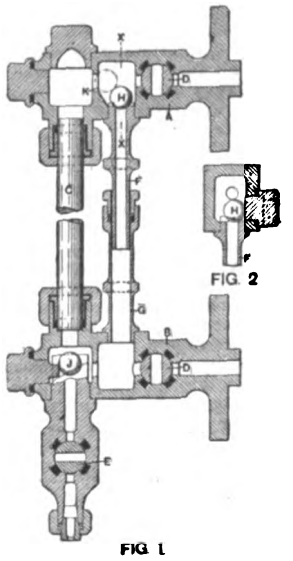
Boiler Furnaces.—*J. Ashworth, Dalton-in-Furness, Lancaster, & W. Kneen, London.*—This invention is an improvement upon a prior invention, described in Specification No. 7393 of 1885, the object of both inventions being the consumption of more fuel per square foot of fire-grate than can be obtained by ordinary arrangements. Air is forced under considerable pressure, by means of a fan or other forcing device, through pipes or passages, continued through the ashpit in the form of a box, and into a pipe or passage behind the bridge, with outlet orifices presented away from the bridge, and so directed that the air from them, or from some of them, is caused to pass across the direction of the draught of the furnace, piercing the products of combustion from the fire, and impinging in admixture with the said products upon fire-brick or other refractory blocks or projections which are situated at the sides



Digitized by Google

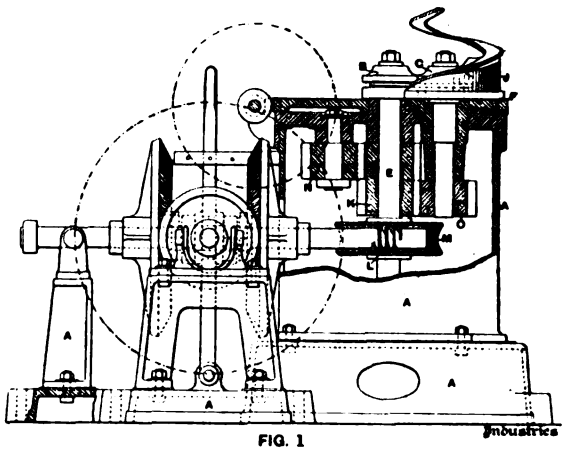
of the combustion chamber at the rear of the bridge, the space at the centre of the flue between those blocks being left clear for draught. Claims: In furnaces, a passage provided with an air-forcing device and carried to behind the bridge and terminating in a pipe or passage with perforations therein, so as to direct the air across the line of draught, and against blocks or projections from the walls of the combustion chamber at each side, arranged so as to leave a space between them.—No. 6876. May 3rd, 1890. 6*d*.

SHUTTLE-CHANGING MECHANISM.—*R. Whytlaw & J. Kincaid, Glasgow.*—This invention relates to shuttle-changing mechanism in use with vertically shifting shuttle boxes, and relates to steadying and locking devices to ensure accuracy of working at high speeds, the general arrangement of parts being illustrated n the partial side elevation of a loom (Fig. 1) and in the series of separate views shown in Fig. 2, these details being illustrated in



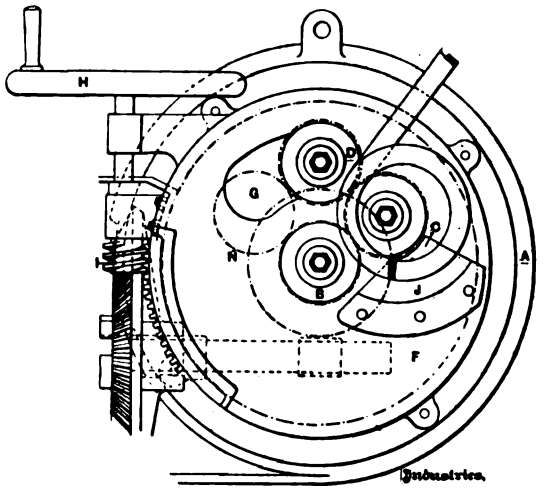
combination in Fig. 3. Additional detail views are given which will presently be referred to. The shuttle box A is connected by its spear B to an eccentric pin C upon a ring D which fits and can turn upon an eccentric sheave E, this last fitting and turning on the crank pin F of a short shaft G which rotates in the frame H. On G there is a pinion H which rotates it and the crank pin F, and G also carries, loosely, the sleeve I, having fixed on it a pinion J for turning E by means of the grooved plate K and the pin L upon the eccentric and fitting the groove in K; by a similar arrangement a third pinion M, also loose upon the sleeve I, turns the outer ring D. The plate N forming part of the mechanism operating D is made to extend in opposite directions, so that it may be balanced. The pinions M, J, and H gear with pin wheels O (only one of which is seen in Fig. 1), each pin wheel being loose on a shaft carried by the frame H and having each four pins or studs P (see Fig. 4) capable of being acted on by a hook Q operated from the low shaft of the loom so as in each reciprocation to turn the pin wheel through a quarter of a revolution. When any pin wheel is acted upon upon by its hook Q, exactly half a turn is imparted to D, E, or F, and the parts are so arranged that the half-turn moves the eccentric D E or crank F from its highest to its lowest position or *vice versâ*. The half-turn of the crank pin F gives a vertical movement equal to the space between one shuttle cell and the next higher or lower cell, the vertical movement of the eccentric E may be equal to the space of one cell or of two cells, and that of the other eccentric D may equal the space of three cells or of four cells. A crank pin and two eccentrics will serve for six shuttles, and as the shuttle box is operated by the combination or by the difference of the distinct motions it may readily be seen that each additional eccentric will double the capacity of the loom. The hooks Q

can act at each second beat of the lathe, but they do not engage with the pins O except when a change of shuttle is required, as may be regulated by a Jacquard mechanism for example. Friction discs are applied to prevent overrunning on the part of the pin wheels, and the locking device referred to in the first paragraph is illustrated by Figs. 3 and 4, in which a lever R is centred at S, and has two segmental concavities fitting two of the pins P and locking them, the part T of the lever R keeps the hook Q from acting on the pin wheel except when required; another lever U turns up under R which it moves into locking position by the action of the strong spring V. When a shift is required the outer end of U is pulled up by the Jacquard mechanism, and a blade spring W causes R to move away from the pin wheel as in Fig. 4. An arrangement of springs X is provided connecting the hook Q with the parts actuating them, to avoid breakage in the event of any obstruction occurring in the working of the apparatus. Claims: Shuttle-changing mechanism as described in combination with steadying and locking devices; the spring yielding devices for preventing damage in the event of obstruction occurring.—No. 8698. June 5th, 1890. 8*d*.



BOILER FLUES.—*J. Fell, Sheffield.*—An improved internal flue for steam boilers, designed for greater strength and durability, is described as follows:—The first of the improvements is applicable to the so-called "parallel" flues of boilers, as usually constructed of rings with successive lap joints, the smaller end of one slightly tapered ring being received by the slightly larger end of the next ring, and so on, the edges of the plates facing away from the fire; in such a flue the inventor flanges up the front or larger end of each flue ring, to form a stiffening flange, each of which flanges may be further strengthened by having an angle or tee iron riveted thereto; or alternate seams only need be flanged for moderate pressures; or the boiler flue may be constructed of plain rings, the meeting ends of each pair of rings being riveted to a channel iron. The second series of improvements consists in coning or tapering successive rings of the flue, and forming the larger or smaller end of each ring into a reverse curve, successive rings being lap-jointed, small end into large end, as previously described; or the large end of a taper ring may be bent inwards around the circumference, and the smaller end bent outwards, successive rings being lap-riveted together. One of the advantages claimed for the construction of a flue in conical sections is that, in case of shortness of water occurring, the area becoming bare is reduced, and the parts covered with water retain their form and prevent collapse or rupture of the flue. Instead of flanging the flue plates a separate flange may be rolled, to which plain conical plates can be riveted in the ordinary manner. Claims: Internal flue rings with flanges on their lap ends; double-flanged belt, zone, or channel plates riveted to the flue rings, for strengthening purposes; flues formed of a combination of cones, substantially as described. —No. 2751. February 16th, 1891. 6*d*.

WATER GAUGES.—*J. A. & J. Hopkinson, Huddersfield.*—The improvements in water gauges described in this specification relate to gauges of the class in which automatic shut-off valves are employed for preventing the escape of water and steam in case of breakage of the gauge glass, the particular objects in this case being to afford large thoroughfares, particularly in the top or steam arm of such gauges, for the flow of water and steam to the glass; to facilitate the removal of the valve and the cleaning of the said ways and thoroughfares; and larger balls may be used than in ordinary gauges. An annular piece has been in some instances employed in the top or steam arm, having a hole of considerably less area than the bore of the gauge glass, to diminish the area for escaping steam in the event of the glass breaking. The inventors do not use this washer, and thus are enabled to effectually blow through the top arm and the glass, and they get, under normal conditions of working, a thoroughfare



equal in area to the full bore of the glass, and the valve is readily removable. Fig. 1 is a longitudinal central section through a gauge constructed according to this invention, Fig. 2 a transverse section on the line X X (Fig. 1). A is the steam arm of the gauge and B the water arm, the arms being connected by a glass tube C in the usual manner; D D are the plug-cocks, and E is the try-cock. In addition to the connection formed by the gauge glass, the upper and lower arms are connected by a supplementary tube of metal, constructed in two sections F G, with expansion joint and stuffing-box as shown. The connection through this tube between the top and bottom arms is closed, under normal conditions (as in Fig. 1), by a valve or ball H resting on a valve seat I at the top of the tube, the seat being inclined (see Fig. 2) and the ball retained thereon by the screw I, and it is obvious that the ball will roll out of the gauge when the said screw is removed. Moreover, the said ball or valve lies within a deep recess formed in the upper arm so as to allow of an unobstructed thoroughfare above it, and by opening the try-cock E a full discharge of the steam is ensured through the upper arm as if no valve were fitted. Any suitable arrangement of bottom valve J, such as that shown, may be employed. Should the gauge glass break, the ball J is forced against its seat, closing the exit, whilst pressure acting through the supplementary tube on the under side of the valve H in the top arm, and assisted by the escaping steam, closes the communication between the boiler and the glass, and stops the escape of steam. A bye-pass K restores equilibrium of pressure after the glass is replaced. The auxiliary or supplementary pipe connecting the top and bottom arms is the essential feature of the invention. The general principle, and not the mere details of arrangement, are claimed. In another modification a spindle is shown for forcing the valve H from its seat to restore free communication after the valve has been in action, and in some cases a spring is employed in connection with this spindle to keep the valve from its seat except when the glass is broken. Other modifications of detail are shown, in which the automatic prevention of the escape of steam is provided for by ball valves resting on inclined seats, and in all cases arranged to give clear thoroughfares, with convenience for cleaning and rapid removal of parts. Claims: In a water gauge the supplementary connection between the upper and lower arms; the same, with the upper automatic shut-off valve; the ball in the top arm, retained on an inclined surface by a lateral support, on the removal of which the ball will roll out; a steam arm, independently of the auxiliary tube, with a ball resting on inclines; the particular arrangements described and illustrated in the specification.—No. 6141. April 22nd, 1890. 11*d*.

HELIX-FORMING MACHINE.—*J. Laidlaw, Glasgow.*—This invention relates to a machine for forming solid bars into helices, such as used in corn conveyers. In carrying out the invention three rollers are preferably employed, one of which is carried on the end of a shaft, the upper or neck bearing of this roller in a framing, serving as an axis for a turntable, arm, or equivalent. The turntable carries another roller at a determined distance from the centre of the turntable, and the third roller is carried on

a short shaft turning on a bearing cast upon the framework below the turntable, which is slotted to allow this third roller to come through the table into a suitable position, and also to permit of the turntable being rotated as much as is necessary without moving the third roller. Since the axes of the first and third rollers have fixed centres, the roller carried upon the turntable may be readily moved into any suitable position relatively to the other two rollers, to give the material operated upon a curve of the required radius. The rollers are grooved to suit the section of the bar operated upon, and after the bar has passed through the bending rollers it is forced over a wedge-shaped surface to give it a helical formation. Fig. 1 is an elevation of the machine, partly in section, and Fig. 2 a plan of the turntable and rollers. In these figures the framework of the machine is marked A, and B C and D are the three rollers, the roller B being carried on a shaft E, the neck bearing of which forms a centre for the turntable F. The third roller D is carried on an independent shaft, which comes up through the slot G of the turntable (see Fig. 2). If the turntable is moved the distance between the rollers C and D will be increased or diminished. The turning of the table is effected by the hand-wheel H and worm-wheel I; thus the relative positions of the rollers can be adjusted to suit the radius to which the bar is to be bent. J is the guiding surface to bend the curved bar into a helix. The rollers B C and D are actuated by reversible worm gearing, as may be seen below, the roller B and spur-wheel Q being driven by the worm L and worm-wheel

M, the said spur-wheel Q gearing with the spur-wheel N, which in turn drives a toothed wheel attached to the axis of the roller D. The wheel O upon the shaft of roller C is also driven by the spur-wheel K. Claims: The combined bending and helix-forming machine, substantially as described.—No. 3697. March 2nd, 1891. 8*d*.

SCREW BLANKS.—*H. Nettlefold & J. Sheldon, Birmingham.*—This specification has reference to the manufacture of screw blanks to be made into screws, and in the heads of which blanks, grooves or depressions are made for the reception of a screw-driver in place of the ordinary nick, the said grooves extending diametrically nearly, but not quite, across the head—that is, the grooves are closed at their ends instead of opening in the under conical side of the head as the ordinary nick does. In making this ordinary closed groove, the impressing tool, on entering the flat face of the head, tends, while being depressed into the head, to force the metal out on either side of it, thus distorting the circular figure of the flat face and leaving a depression or deficiency of metal at the ends of the groove, and leaving the sides of the groove rounded. To produce the said closed groove without distorting the head or rounding the edges or ends, the upsetting tool employed upon the head of the blank is provided with two crescent-shaped depressions in its under face, these depressions being of somewhat shorter radius than the circular head of the blank, and situated symmetrically at opposite sides of the centre of the tool. Slight parallel depressions are also made in the die, at a distance apart slightly greater than the breadth of

Digitized by Google

groove desired, these depressions crossing the plane of the die face from one crescent-shaped depression to the other. Thus, on the otherwise flat face of the head produced on a blank are formed two crescent-shaped projections and two parallel ribs, upon which the impressing tool operates in such a manner that the groove made is in a line crossing the centre of the face of the head, and bisecting each of the crescent-shaped projections, and while the metal spreads outwards at each of the longer sides of the tool the crescent-shaped projections are flattened by the flat face of the tool and forced towards the ends of the closed groove which is in course of formation. The parallel ribs on either side of the groove are also flattened, and the rounding of the edges of the groove prevented, the projections supplying material just when it would otherwise disappear and permitting rounding to take place. Claims: Forming, on the face of the blank, ribs or projections which supply deficiencies of metal during the operation of grooving in order that the circular form of the head may be preserved, and the edges of the groove remain sharp.—No. 15709. October 7th, 1889. 8*d*.

Steam Boilers.—*O. Imray, London.* (*The Hogan Engineering Company, New York.*)—The object of this invention is to promote the circulation in water and steam boilers having sections supported side by side, or one upon the other, and this object is effected partly by furnishing distinct channels for the upward and downward movement of the water, and partly by facilitating the downward movement of the fluid in the cooler parts of the boiler, while obstructing any movement of the fluid into such portions from the hotter parts of the boiler. Such a result is secured by providing connections between the upper parts of the several sections for the upward passage of the hotter fluid, and separate connections between the lower parts of the sections for the downward passage of the cooler fluid, the cooler fluid being preferably protected from the gases heated in the fire-box. The invention is shown herein as applied to house-heating boilers, made by dividing the water space into separate cast-iron perforated water sections, having intermediate smoke chambers. In the illustrations Fig. 1 is a vertical section of a sectional cast-iron boiler, Fig. 2 is a plan of one of the water sections over the fire-box, and Fig. 3 is a vertical section of the same on the line X X of Fig. 2. The boiler is shown formed with annular fire-box sections A and B, four horizontal sections C, D, E, and F, and a top section G, from which the heated fluid

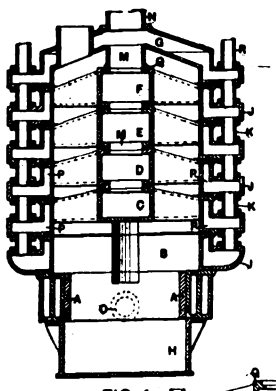


FIG. 1

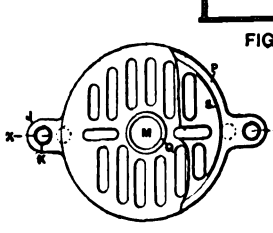

FIG. 2

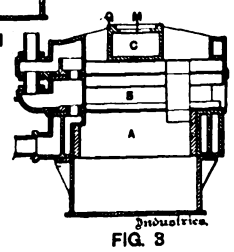

FIG. 3

is discharged. H is the ash-pit and I a door aperture in the section B. Hollow lugs J are projected from two opposite sides of the sections B to G inclusive, and are connected by thimbles K screwed into the lugs with jam nuts L. The sections C to G, as shown in Fig. 2, are round, and are formed at the centre with nozzles adapted to fit into one another, and perforated to form a central connecting passage M. The top section is furnished with a water outlet pipe N, and the bottom section with a water inlet pipe O. Depending water legs P are projected downward from the margins of sections C to G, thus separating the sections by intermediate smoke chambers, the smoke passages being provided at opposite sides with nozzles Q to heat the fluid in the central water passage M. The top of each section, as shown in Fig. 1, is sloped upward towards the nozzle, to facilitate the movement of the heated fluid toward the centre of the boiler, and pipes upon the top section form, with the thimbles K, a continuous external passage from the section B for the return fluid from the radiators. The fire-pot section A is a hollow ring, subdivided to circulate the feed-water, and connected by hollow lugs with the section of above. The pockets J and thimbles K being exterior to the water legs P, are colder than the contents of the boiler, and thus serve as downward conductors for the return fluid from radiators, when the latter are in connection with the boiler. The pockets being open to the water leg at the margin of each section serve as intermediate connections between the colder conductors and the contents of each section, and thus permit a circulation of the colder fluid from such section downward when required. To prevent the heated fluid within the section from flowing into the pockets a deflector is provided at the entrance to each pocket. Other modifications of the arrangement are described, and by any of the constructions the circulation may be regarded as trapped, and the heated water directed positively toward the central passage M, while all the colder fluid is returned by the thimbles K to the fire-box section. The guard in Fig. 2 keeps the contents of the jacket free from disturbance, and prevents the setting up of a purely local circulation. Claims: In eleven combination claims, the general arrangement and the details of a boiler with a central water passage, and with external water conductors, substantially as described.—No. 5738. April 15th, 1890. 11*d*.

ELECTRICITY.

Railway Brake.—*H. E. Walter, London.*—According to this invention the speed of trains is reduced by means of the reaction produced by causing Foucault currents to be induced in the rails by magnets carried by the train, with their poles in close proximity to the metals. By these means, it is said, there is obtained a retarding force greater than that of a brake shoe, and the great heat produced is left behind in the rail; also, there is no wear or tear upon either the magnets or the rails, so far as the braking action is concerned. Two or more magnet poles, preferably of opposite polarity, are set in a line parallel with the rail and in close proximity to it, so that magnetic lines of force pass through the rail from one magnet pole to the other. Various other arrangements of magnets are discussed, and the suggestion is made that in order that the magnets may be brought very near to the rails, but may still have a definite clearance, they could be attached to the axle boxes of two pairs of wheels spaced at a short distance apart. Also, the frame carrying the magnets, in this example, might be borne by rubber washers resting on the axle boxes, so that considerable clearance would exist, except when the magnets were energised, whereupon they would draw themselves closer to the rail, compressing the washers, and diminishing the clearance. The magnets could be energised by storage batteries carried in the carriages, or by a dynamo carried by the engine. Claims: An electro-magnetic brake for railways on the principle above described; also the particular arrangements of magnets and accessories described in the specification.—No. 8720. June 5th, 1890. 8*d*.

Electrical Welding.—*Lemp & Schmidt, both of Lynn, Mass., U.S.A.*—The process here described is particularly applicable to the electrical welding or brazing together of separate strips or bars, laid side by side; it consists essentially in feeding the parts through suitable devices to force them together, the heating current being passed longitudinally through the portions of the work which are approaching the pressing devices, so that the heating is extended over some length of metal, which becomes hot before reaching the welding rolls. A greater speed of operation is possible, and the cooling effect of the pressing rollers is less than where the current passes through the bars at right angles with their course. As a source of current it is preferred to employ a transformer having a large number of turns traversed by alternating currents, and a secondary consisting of a slit and heavy bar of copper, the two ends of which form the poles of the apparatus and deliver the current to the work by contact rollers or otherwise. The pressure rollers are of steel, and their supports are insulated. The two bars to be welded pass separately between pairs of contact rollers, and are brought together just before they reach the pressure rollers, the path of the current being from one pair of contact rollers along a length of one bar to its junction with the other bar, and back along the other bar to the other pair of contact rollers; or the bars to be welded may each have a current led along them in the direction of their lengths—*i.e.*, in parallel circuit—the current being led to opposite sides of adjacent bars by one pair of contact rollers, and withdrawn from the same bars further along by another pair of contact rollers. Claims: Welding, soldering, or brazing bars or strips by pressure arrangements, whilst sending current longitudinally through the bars; also the arrangements of rollers, substantially as described above, in combination with a transformer of the type referred to.—No. 3336. February 24th, 1891. 8*d*.

Electricity Meters.—*E. Hartmann & W. Braun, Bockenheim, Germany.*—In the electricity meter forming the subject of this invention a unipolar apparatus on the principle of Barlow's wheel is employed, through the copper disc of which the current to be measured is caused to pass radially, the magnetic field being formed by a powerful electromagnet magnetised by a constant current. The revolutions of the disc under these conditions are proportional to the quantity of electricity passing through it, when, with a constant field, the current to be measured is proportional to the Foucault currents, and in order to comply with these conditions care must be taken that there is nothing to interfere with the formation of these local or eddy currents. It is pointed out that in case the magnetic field presents the same form and extent as the path of the current passed through the said disc, for example, an e.m.f. also results from the rotation of the said disc in the magnetic field, which acts in opposition to and weakens the current to be measured, and in this case the local currents are not produced in full, so that a special brake magnet is necessary; but to obviate this the inventors, by means of lateral enlargements on the pole pieces, enable the local currents to form close up to the passing current, which arrangement is said to give most advantageous results with regard to the aforesaid ratio of the currents. The copper disc is secured to a shaft upon and in gear with which are toothed wheels operating any convenient type of registering mechanism, the current being led to the disc by spring arms or through mercurial contacts into which the disc or parts in connection therewith may dip. To increase the magnetic induction and to obtain uniformity in the magnetic resistance with regard to all the lines of force, the copper disc is perforated with a number of holes, into which are inserted plugs of soft iron. These holes extend radially upon the face of the disc, so that they are found close together at the parts where the greatest resistance to the lines of force is presented. Claims: In electricity meters in which the current to be measured is caused to pass radially through a disc in a constant field, enlargements on the pole pieces as described; also the introduction of pieces of soft iron into the disc.—No. 3609. February 27th, 1891. 6*d*.

Secondary Batteries.—*W. Roberts, Toronto, Canada.*—This invention relates to the form and arrangement of surface of an electrode, to the coupling of these electrodes together in a cell, to their insulation, and to a method of guarding against the possibility of the occurrence of short-circuiting within the cell. The electrode is formed, in the usual manner, of two plates, preferably of lead, which are brought face to face so that star-shaped or other openings in each plate coincide, the metal of the coincident faces of the plates, between the openings, being beveled away so that the entire inner surface of the plates is exposed to electrolytic action, and free circulation of the current over the surfaces in question is afforded, and the oxide of lead between the plates practically forms a continuous sheet, and is prevented from dropping out. The beveling above mentioned exposes a considerable surface area of metal as compared with a correspondingly perforated plane surface. Lugs on one plate of each pair are bent over the companion plate to secure the two together. To insulate and couple the electrodes together, hard rubber bolts are provided, which pass through the plates and also through intermediate hard rubber separating sleeves. The inventor also specifies an arrangement of coupling strips for two or more cells, in which the strips to which the electrodes are secured have their ends turned up and secured together by a threaded bolt and nuts, the turned-up end in some cases being used to make contact with a terminal plate to which wires are secured, also by a screwed bolt and nut. The rubber bolts before referred to, which secure the electrodes together, serve also to keep the positive electrodes above the floor of the cell, to prevent short-circuiting, the negative electrodes being provided with feet which support the whole series. Claims: The beveling of the inner surfaces of plates forming a secondary battery electrode, the outer surface of each plate being a plane surface; the method of securing the pair of plates by lugs; the turned-up ends of coupling strips secured to each other or to terminal plates by screwed connection; the coupling and insulating bolts and sleeves, and the feet in combination therewith, the whole to prevent short-circuiting; also a pair of plates not described above, having uneven inner sides in combination with a central plate having two uneven sides, a paste being placed between opposing plates.—No. 1425. January 26th, 1891. 8*d*.

CHEMISTRY.

Yellow Colouring Matter.—*O. Imray, London.* (*The Farbwerke vormals Meister, Lucius, & Brüning.*)—This invention relates to the production of a yellow colouring matter by the action of tetrazodiphenyl upon orthocresotic acid. For the preparation of the tetrazodiphenyl salt sulphate of benzidine is used in the form of a paste of from 15 to 20 per cent. About 200 parts by weight of this paste, corresponding to 28·2 parts by weight of pure sulphate, are mixed in a suitable vessel with about 350 parts by weight of cold water, and to the mixture are added 29·5 parts by weight of hydrochloric acid of 30 per cent. The mass is cooled down by means of ice to + 10° C., and at this temperature a solution of 14·07 parts by weight of nitrite of sodium, dissolved in from 60 to 80 parts by weight of cold water, is caused to flow in slowly. After having been kept agitated for some time—say, from half an hour to an hour—the benzidine sulphate will have dissolved entirely and the diazotising will be completed. At the same time are dissolved in a vessel of sufficiently large dimensions 31 parts by weight of orthocresotic acid, by means of 19·2 parts by weight of caustic soda of 100 per cent., and about 1,000 parts by weight of cold water. The clear solution is cooled down to + 1° C. by means of ice, and the solution of the tetrazodiphenyl is caused to flow into it under continuous agitation, which is kept up for ten hours, after which time the mixture is heated slowly to 50° C.; it is kept agitated for one hour more, and then the temperature is raised to 60° C. The colouring matter is precipitated by means of common salt and pressed off hot in a filter press. The cakes are submitted to hydraulic pressure and afterwards dried at a temperature between 60° and 70° C. Claims: The production of a yellow colouring matter by the action of a tetrazodiphenyl salt upon orthocresotic acid substantially as described; the yellow colouring matter produced substantially as described.—No. 8506. June 2nd, 1890. 4*d*.

MISCELLANEOUS.

Miners' Lamps.—*A. Howat, Old Trafford, Manchester.*—The improvements embraced by this invention are particularly applicable for testing or trying for explosive gases, and it is preferred to employ a lamp of the construction described in specification No. 17410 of 1889, wherein the wire gauze cylinder is covered with a metal shield or bonnet which rests upon the upper side of the deflector of the lamp. The said deflector forms the roof of the air chamber, the bottom of which is formed by a horizontal ring forming part of the lamp framing, the outer side of the air chamber being formed by a short cylinder dependent from the ring, and the inner side being formed by a longer cylinder. An additional air inlet for gas testing purposes is provided by tubes, the lower ends of which are fixed in the deflector and communicate with the top of the air chamber, and the upper ends terminating in the top of the lamp, and being open to the atmosphere. In the air chamber lies a horizontal ring, which may be raised and lowered from the exterior of the lamp. When it is raised against the roof of the air chamber and maintained in position by a suitable catch, it closes the lower ends of the additional air tubes, and consequently all the air supplied to the burner has to enter through the ordinary inlet. But when the lamp is used for gas testing, the ring is allowed to fall upon the top of the high collar, closing the ordinary annular inlet, so that the air supplied to the lamp is drawn into the annular air space through the special air tubes, and the presence of any explosive gas will be readily detected. Claims: The combination of the ordinary air inlet at or near the bottom of the air chamber, with an additional inlet for supplying air to the upper part of the chamber, and means such as the movable ring for opening and closing either inlet; also the means for raising and lowering the ring by a rocking arm operated by a rod which is retainable by a catch.—No. 7749. May 19th, 1890. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE "LITTLE GIANT" TURBINE.

The horizontal turbine we illustrate herewith is a double-wheel one, having two tiers of buckets, side by side, keyed to the same shaft, both running in the same case, but discharging into separate draught tubes. The case is cast in one piece, is a scroll in form, and is provided with two planed foot-plates. To each side of the case bearings are attached for the wheel shaft, these bearings being adjustable to compensate for wear, and to keep the wheel running true in the case. On the outer ends of the wheel shafts are seats for couplings. The lower faces of the discharge hoods are planed true with the foot-plates of the case, forming thus one continuous face, to which a strong iron bed-plate is attached, with openings to correspond with the same in the discharge hoods. On the underside of the bed-plate, and around the discharge hood openings, is a suitable face with bolt holes to match the holes in the discharge hood flange, the bolts in this being long enough to attach the flange of the draught tube. The simplicity of the gate arrangement is worthy of attention, as there is but one gate, which may be easily kept in order. There are many situations where a turbine placed upon a horizontal shaft can be used at better advantage than on a vertical shaft. By using a horizontal shaft and placing the turbine shaft some distance above tail water, nearly the whole effect due to the head can be obtained by using an air-tight tube for a discharge tube, the lower end of which extends into the tail water. This mode of setting a wheel admits of placing a pulley directly on the turbine shaft and having belting to the line shaft. This turbine is altogether constructed so as to form a strong and compact motor. It is well adapted for electrical work, as it allows the dynamo to be attached direct to the turbine shaft, and thus dispenses with pulleys, belting, or gearing. The sole agent for it in this country is Mr. S. Howes, 64, Mark Lane, London, E.C.

THE DUTCH ROYAL STEAM PACKET COMPANY'S STEAMER "VAN GOENS."

We illustrate on our two-page supplement, in Figs. 1 and 2, a sectional elevation and awning-deck plan of one of three steamers built for the Royal Steam Packet Company at the "Koninklyke Fabriek van Stoom E. A. Werktuigen," Amsterdam. The above company obtained a concession for carrying passengers and cargo in the East Indies, between the different ports of the Archipelago, starting on the 1st January last. Sixteen vessels were taken over from the old line to be reconstructed, whilst thirteen new ones were built in Holland. The new boats are built after three types, called A, B, and C, according to their respective sizes and the distances run, and are all named after the late General-Governors of Netherlands, India. The A type vessels were built by the Royal Shipbuilding and Engineering Company "de Schelde," at Flushing, and are named "Both," "Reaal," "Coen," and "Maetsuicker." The B type vessels, one of which is shown in our illustrations, are the ten-mile steamers, "Van Goens," "Reynst," and "Speelman," built at the Royal Factories at Amsterdam, and the twelve-mile steamers "Carpentier" and "Van Diemen," built by the Dutch Steamship Company "Feyenoord," Rotterdam. The C type vessels consist of the "Van Rhiebeeck," built by Messrs. J. & K. Smit, Kinderdyk, the "Reyniersz" and "Zwaerdekroon," built by the Shipbuilding and Engineering Company "de Maas." All the above vessels are either of steel or iron. One of the C type, however, was composite built, in order to ply in waters where docking is difficult. Messrs. Huygens & Van Gelder, at Amsterdam, constructed this vessel, named "Camphuys." The illustrations we give in our two-page supplement represent the "Van Goens." She is one of the ten-mile B type boats. Her dimensions are: — Length, between perpendiculars, 220ft.; breadth, moulded on frames, 30ft. 10in.; moulded depth to main-deck, 15ft. 9in.; height of awning-deck above main-deck, 7ft. 3in.; load draught, forward, 11ft., aft, 12ft. 6in. The steamers are all built to the highest class of "Veritas" special survey. They are of the awning-deck type, and are schooner rigged, with two so-called pole masts. This class of boat is fitted for 22 first-class, 18 second-class, and about 200 third and fourth-class passengers. The accommodation for the passengers has been carefully considered, with special reference to a first-class passenger service in a hot climate. Saloon and state-rooms for first-class passengers are perfectly lighted and ventilated. The fittings and decorations of the saloon are all in the same style. The sides or walls are of polished oak, divided by balusters into a series of panels having blue and brown tiles from the well-known earthenware manufactory at Delft, and painted after the most talented Dutch artists. The table, of polished oak, in the first-class saloon can be divided into a number of small card tables.

THE "LITTLE GIANT" TURBINE.

General View.

The floor is not carpeted, but Brussels strips extend in the passages of the saloon and cabins. The state-rooms are exceptionally commodious and comfortable, and are supplied with Crosbie's patent iron bedsteads and spring wire mattresses. Every first-class cabin is fitted for two passengers; one of the two berths, however, can be folded up against the wall if not used.

The second-class accommodation is placed forward, and the rooms are neatly finished in wood, without tiles, being also airy and well lighted. The third and fourth class passenger accommodation being for the use of soldiers and natives, is on the main deck. The spaces are well ventilated and lighted, and are disposed for hammock berths, if wanted, although it is the custom of the natives to lie on the deck on their own mats.

The accommodation for the captain, officers, engineers, and crew is also extensive, and suitable to the climate. As it is the intention to carry soldiers, if necessary, every ship is provided with a powder and shell room.

On account of the dangerous harbours in the islands of the Archipelago, the vessel carries a steam launch, with two 26ft. sloops, specially arranged for carrying cargo, and for being towed up the rivers by the steam launch. A lifeboat, a cutter, and a gig complete the life-saving apparatus of the vessel. Duinker's patent disengaging screws are applied.

A refrigerating and freezing room, a number of fresh-water tanks, and a filter secure to the passengers agreeable living even in the most desolate places of the Archipelago.

The engines are of the triple-expansion surface condensing type, having cylinders 17in., 26in., and 43in. diameter respectively, with a stroke of 39in. The high-pressure cylinder has a piston valve, and the intermediate and low-pressure cylinders have flat valves, the steam expansion being controlled by link motion. The cylinders are not steam jacketed, but are fitted with cast-iron liners. The condenser is cast with the engine framing and fitted with 592 brass tubes of $\frac{3}{4}$in. outside diameter, giving a cooling surface of 1,466 square feet. The air pump is 17in. diameter, with a stroke of 19$\frac{1}{2}$in. There are two single-ended return tubular boilers, 11ft. 3in. internal diameter and 9ft. 9$\frac{3}{4}$in. long, with two Purves' ribbed furnace tubes in each. The heating surface of each boiler is 1071·5 square feet, and the grate area 35 square feet, the working pressure being 160lb. per square inch. The propeller is of the Griffiths' type, 10ft. 9in. diameter, having four steel blades, and a pitch variable from 16ft. 6in. to 18ft. 6in. The ship is built to run at an average speed of 10 knots, and in her trials made an average of 12·65 knots per hour., the engines developing 846 i.h.p. A considerable share of the success of these vessels is, we are informed, due to the exertions of Mr. J. F. J. de Bruyn Kops, who superintended the construction of the ships, and to Mr. R. A. Meyer, who superintended the construction of the engines.

NEW RADIAL REVERSING VALVE GEAR.

The gear illustrated on page 506 belongs to that class of radial gears actuated by the connecting rod, and is the invention of Mr. James Dunlop, of 138, Aitkenhead Road, Glasgow. The chief features of the invention are the links connecting what is termed the actuating link to the valve rod, and the method of controlling the same by the double connection to the reversing lever. By referring to Fig. 1 it will be seen that the valve lever A, being controlled by a link B from an arm on the cross-head, is thereby caused to move in unison with the piston. The correcting link C being so proportioned as to form, in conjunction with valve lever A, a parallel motion, the vibrating link D will vibrate equally on either side of its middle position, its vibrations being timed with the piston, while their extent is regulated by the connecting rod. As the lengths of the valve lever A on either side of its fulcrum on the vibrating link D are so proportioned that the end nearest the fulcrum travels the amount of lap and lead, this travel will be constant and in direct opposition to the piston. For the purpose of actuating the valve in such a manner as to admit of reversing and of varying the amount of its movement, the actuating link E is controlled at its adjustable end by a link H from the reversing lever, the distance it is moved to one side or other of its middle position being practically the same as if that distance was one arm of a bell-crank travelling the required travel of the valve, the length of the other arm being equal to the length of the actuating link E, and travelling the amount of the vibration of the link D, the motion being reversed as it passes from one side to the other of its middle position. It will be noticed that the connection between the adjustable end of this actuating link E and the valve rod consists of the corrective link F and valve connecting link G, the point where they join being controlled from the reversing lever by the link I, which is jointed to the lever at a lesser radius than the link H. One purpose of this second connection to the reversing lever is to angle the corrective link F in such a

NEW RADIAL REVERSING VALVE GEAR.

(*For description see page* 505.)

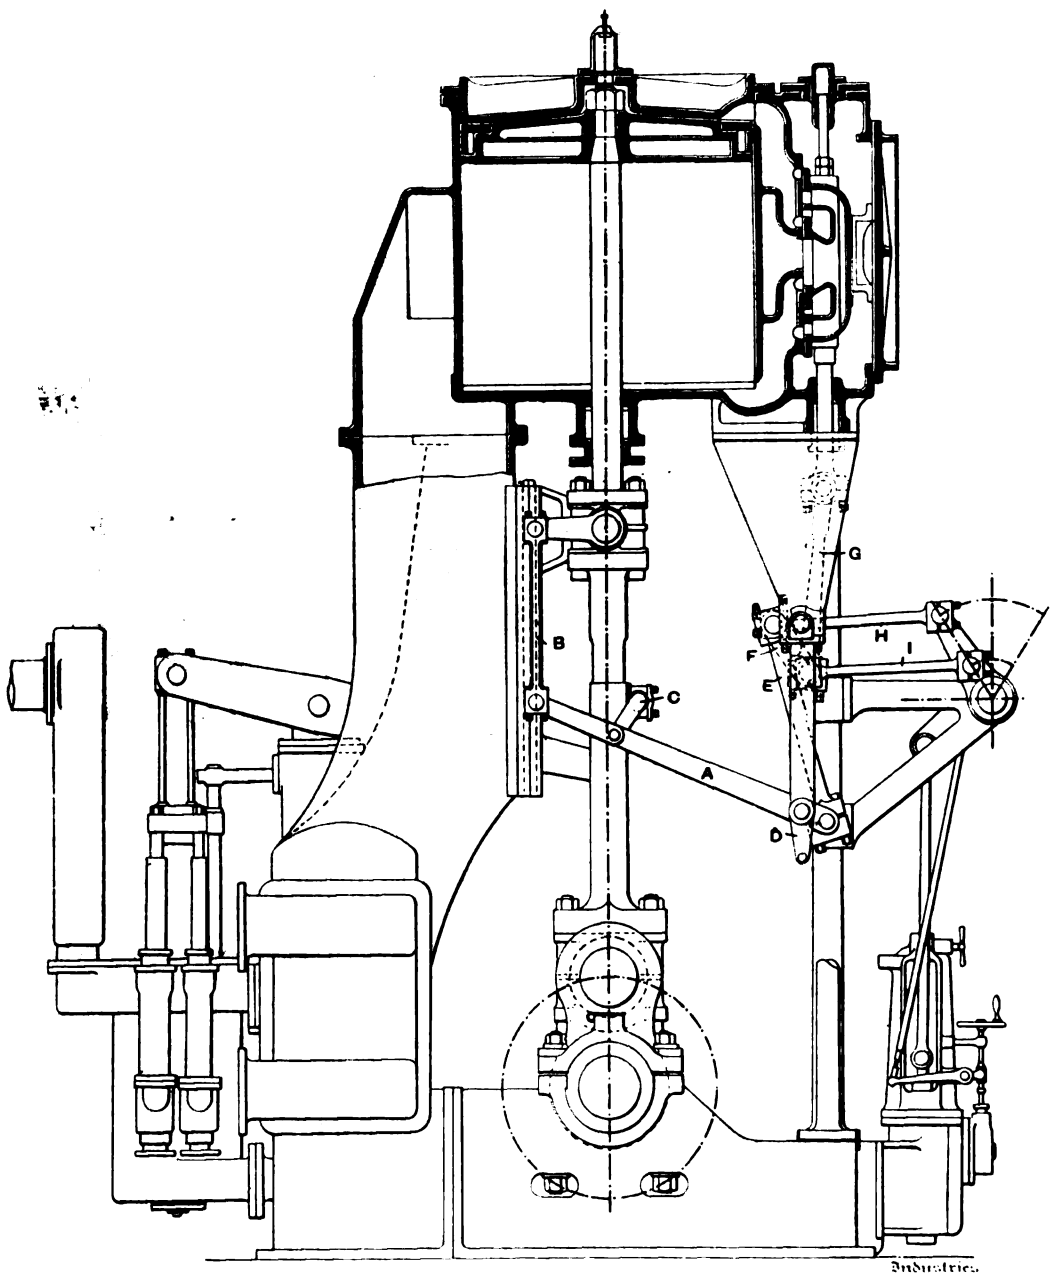

FIG. 1.—GENERAL VIEW OF GEAR.

manner as to compensate for the arcs described by the ends of the actuating and valve connecting links. Another important feature is that the connection to the valve rod is more direct than in other radial gears. As a direct result of this arrangement, it may be expected that the wear and tear will be greatly reduced, and also the first cost. As regards the steam distribution, it is exceedingly good, as the valve openings and cut-offs are practically equal for both ends of the cylinder under all conditions of working.

Mr. Dunlop has several modifications of this gear suited for application to locomotive, marine, and other engines, including a variable expansion arrangement intended principally for compound locomotives.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

(*Concluded from page* 484.)

REPORT UPON TRIALS OF THE S.S. "IONA."

Subsequent Trial by Chief Engineer.—After the trial above described had been carried out, the "Iona" made a voyage up the Mediterranean, and on her return journey from the island of Serpho to Rotterdam, on 15th August 1890, when the vessel was off the coasts of Tunis and Algeria, the chief engineer of the vessel, Mr. J. Fiddes Brown, carried out a trial on his own account. The weather was fine throughout the trial, with light head winds, but the vessel was rolling somewhat during the latter part. The mean draught during the trial was about 20ft. 9in. The trial commenced at 5.33 a.m., and was continued until 4.26 p.m. by chronometer, thus lasting for 10 hours 53 minutes, or 653 minutes. As in the Committee's trial in July, the coal was twice weighed, the difference between the two methods of weighing being only 1·2 per cent., which is accounted for by the difficulty of weighing accurately during the rolling of the vessel in the latter part of the trial. The total coal used was 10,631lb., or 16·3lb. per minute. Indicator diagrams were taken from each end of each cylinder every half-hour throughout the whole trial. Two Richards indicators were used; one was kept constantly on the high-pressure cylinder, while the other was changed between the intermediate and low pressure cylinders. The indicators were attached to the cylinders by the usual long pipes and bends, and top and bottom diagrams from the same cylinder were taken on each paper. In this way twenty-two complete sets, or sixty-six separate papers, with two diagrams on each, were obtained. The maximum indicated horse-power from any one set of diagrams was 730, taken at 1 p.m.; and the minimum from any one set was 683·5, taken at 3·30 p.m. The revolutions were counted once in each quarter of an hour, and the mean of all the observations gave an average speed throughout the trial of 63·9 revolutions per minute. The mean barometric pressure throughout the trial was 30·10in. of mercury, or 14·8lb. per square inch. The mean pressures in the first and second receivers were respectively 41·5lb. and 1·8lb. per square inch above the atmosphere. The mean readings of the water gauges connected with the forced draught apparatus were as follows:—

Position of Gauge.	Pressure.
On air-trunk near fan	1·03in. of water
On air-trunk at back of boilers ...	0·78in. ,,
On ashpits, mean of four gauges...	0·32in. ,,

The mean speed of the fan engine was 218·5 revolutions per minute, and the indicated horse-power developed was 2·6. As

* Report prepared by Professor Alexander B. W. Kennedy, F.R.S., Chairman of the Committee, for the Institution of Mechanical Engineers, and read at the meeting of the Institution on the 31st ult.

* Indicated by a pyrometer in uptake of furnace.

in the Committee's trial in July, steam was supplied to the fan engine from the donkey boiler. The mean temperature of the gases in the uptake of the furnace, as indicated by a pyrometer placed at a height of 6½ft. above the level of the firebars, is given as 672° Fahr. The principal results of the August trial are given in Table II., along with those of the Committee's trial, and it will be seen that these two sets of results agree remarkably well. The only essential difference between them is that in the August trial the coal is given as 1·38lb. per indicated horse-power per hour, whereas in the July trial it was 1·46lb. per indicated horse-power per hour. The same description of coal was used in both

of the trials. In the August trial the feed-water was not measured, and the drain and jacket water was delivered direct into the hot-well instead of being allowed to collect gradually in measuring tanks before being mixed with the feed-water. In consequence mainly of this, the feed-water entered the boiler at a mean temperature of 157° Fahr., whereas in the July trial the mean feed-temperature was 106° Fahr. The difference between the amount of heat taken up in the boiler by 1lb. of water in the two trials is 4·6 per cent. of the larger amount. The difference between the two fuel consumptions is 5·5 per cent. of the larger amount. These two results strikingly corroborate each other, and show how exactly it is possible to estimate beforehand the actual saving due to the heating of the feed-water. The consumption of coal in the August trial, if calculated for the conditions under which the July trial was carried out, would be 1·45lb. of coal per indicated horse-power per hour. The continuous variations of boiler pressure, cylinder mean effective pressures, horse-power, and speed during the August trial are shown above in Figs. 18 to 21.

Speed of Vessel.—Besides careful measurements from the ship's chart, taken by Captain Cranston at regular intervals throughout the Committee's trial and embodied in the ship's log, a continuous registering log was employed to estimate the speed of the vessel, and the reading was noted every half-hour during the

trial by the captain or the officer on watch. The extract from the ship's log herewith, relating to the time of the trial, has been kindly furnished by Captain Cranston.

The distance recorded by the registering log during the trial was therefore 179·5 — 44·5 or 135 nautical miles in 16 hours, which is equivalent to a mean speed of 8·4 knots. The distance traversed by the ship during the trial as measured from the chart was 138 nautical miles, which is equivalent to a mean speed during the trial of 8·6 knots. There is added to this report Table II., showing the leading results of the trial of the "Iona" carried out by the Committee on 13th and 14th July, 1890; and beside these are placed the corresponding figures for the subsequent trial made by the chief engineer on 15th August. There is also added an appendix giving a list of the members of this Institution and others who have taken part in the Committee's trial.

Fig. 24 gives a general view of the arrangement of the measuring tanks as used in the Committee's trials in July, and Figs. 22 and 23 are diagrams connected with the chief engineer's trial made in August of last year.

Appendix.

Staff of Observers.

* Members of the Institution are marked with an asterisk.

One watch was taken by Mr. A. G. Ashcroft, along with Messrs. A. Brownsword, W. A. Cloud, W. Kennedy, L. A. Legros,* P. S. S. Pilcher, and E. C. de Segundo. The other watch was taken by Professor Kennedy,* along with Messrs. H. F. W. Burstall, H. R. J. Burstall,* J. T. Ewen, S. B. B. Hebb, J. S. Ruell, and J. H. Sharman. Mr. C. J. Wilson collected the gas samples during the whole of the trial. Mr. John R. Fothergill,* who is the superintending engineer for the owners, and Mr. Thomas Mudd,* the manager of the Central Marine Engine Works, were both on board; and Mr. J. Fiddes Brown, chief engineer of the ship, as well as his staff, gave every possible assistance in the work. The Committee are much indebted also to Captain Joseph Cranston and his officers for their courtesy throughout the whole of the operations.

THE BALANCING OF CENTRIFUGAL PUMPS.*

BALANCING Centrifugal Pumps is the announced theme for my remarks, but before entering upon that subject I think it will be a matter of interest to the members to say something of the nature, origin, and history of these useful implements, especially as this matter is not very well understood.

Centrifugal pumps are the latest invented among water-raising machines. Other standard pumps are centuries old, and for a long time there has not been much change in the principles of their construction, but, as remarked, centrifugal pumps are a modern invention, not dating back more than fifty years in any recognisable form. I have said they are imperfectly understood, and to support this statement and in advance of saying anything of their history, I will refer to a report of the American Commissioners who were appointed to attend the Vienna Exhibition in 1873, to report on machines and manufactures shown there. This commission consisted, as now remembered, of five engineers. I am not able to give you their names or the exact words of their report, but the substance of it involves the following propositions:—(1) Appold was the introducer of this class of pumps; (2) they were mis-named "centrifugal," because they do not operate by centrifugal force at all; (3) they operate by pressure, the same as a turbine water-wheel; (4) when people understand their method of operating we may expect much improvement; (5) they should have disc runners, because the fan wheels will soon wear out.

Comment is not necessary; and I think in the face of this information, now only seventeen years old, my proposition that the pumps are not understood, will be conceded. The report mentioned goes on to say that they seem to be very simple machines, involving no intricacy whatever. I think the members of that commission are better informed now, at least it is to be so hoped. I once thought myself that these pumps were very simple machines, but when I commenced the manufacture of them here in California, nine years ago, I soon found to my astonishment they were not simple machines at all, but, on the contrary, very intricate machines, involving many peculiar principles and conditions that nobody would suspect until they tried the experiment of working them under high and low heads, and other varying conditions. While the theories and principles of constructing such pumps seem to be reliable and correct mathematically, the theoretical rules cannot in many cases be applied in practice, and it requires different proportions of various parts from what computation will furnish.

In respect to the diameter of the wheels, for example, theoretical dimensions are not applied in practice, because too small and involving too great rotative speed; neither can the section of the waterways be made uniform. The curve of the vanes cannot follow any hard and fast rule, because the form varies with the head, and there are other elements which have to be adapted to the circumstances of each case.

I promised to say something about the history of these pumps. Centrifugal pumps are, so far as I know, an American invention. A very good centrifugal pump was made in the United States as early as 1818, thirty years before any pumps of the kind were made in Europe. I do not know just where, but I think somewhere near Boston. They operated very successfully, and a number of them were made. In 1830 such pumps were exhibited in the city of New York at an exhibition held there. They were then called the "Massachusetts Pumps," and are illustrated in Fig. 1. As remarked, I have never been able to

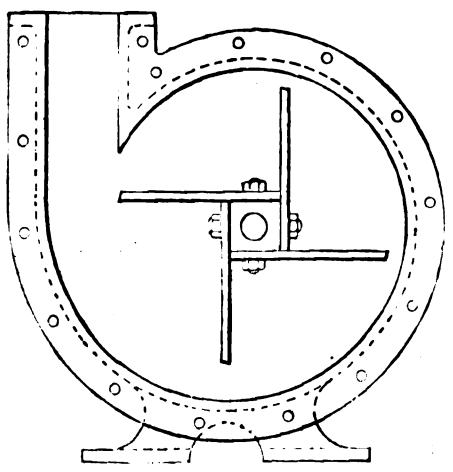

FIG. 1.

find out who was the inventor of the original "Massachusetts" pump. It was perhaps an "evolution" of a neighbourhood. [Since the above was written, Mr. J. E. Hodgkin has shown conclusively, from printed descriptions of the celebrated French engineer and mechanician, Papin, that he invented centrifugal pumps, and was familiar with their action in 1689, more than 200 years ago, but no practical use followed his discovery. This machine of Papin's was the one known as the "Hessian Suck."]

In 1839 Mr. Andrews, of New York, improved the pump by applying the volute or spiral casing. This added a good deal to the efficiency at low heads, but nothing perhaps at high heads.

About that time Mr. James Stuart Gwynne, of London, now of the firm of Messrs. Gwynne & Co., in the same city, while at Pittsburgh, Pa., had his attention drawn to this "Massachusetts" centrifugal pump, and made at least one pump there that was sent to a mine in New Jersey.

* Abstract of a paper read by Mr. J. Richards, of San Francisco, before the Technical Society of the Pacific Coast.

About 1846 Mr. Gwynne went back to England, taking with him the centrifugal pump, called in England at that time the "American pump." He commenced its manufacture there, and very successfully. At the Exhibition of 1851 he was met in competition by Mr. Appold, whom the American Commissioners to Vienna claimed to be the first inventor of these pumps. I will mention here that in England Mr. Appold comes in for a great

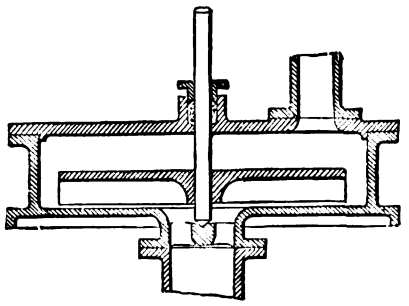

FIG. 2.

share of the credit for inventing centrifugal pumps; but I am inclined to the opinion that he is entitled to very little credit in connection with the pump. He has never done anything so far as I know except to introduce curved vanes. Previously these had been made straight, or nearly straight. As to the value of that invention, I will digress a little and say something about the vanes, although this is hardly the proper place to introduce them; but I want to explain what Mr. Appold had to do with these pumps. The diagram, Fig. 3, was sent to an engineering journal about three years ago for publication by Mr. Charles Brown, of the firm of Messrs. Sulzer Bros., of Winterthur, Switzerland, which I believe is one of the foremost machine shops of the world; I also think Mr. Brown one of the most eminent engineers living at the present time. In the construction of recent Government works in Italy, which are very extensive, he was selected by Sir William Armstrong & Co. to put down their novel and extensive plant, which was done in a very successful manner. Writing in September, 1886, Mr. Brown states:—"About 1856 I carried out a series of experiments to determine the best form and proportion for centrifugal pumps, and found that the form of vanes had a great influence on the speed required. The sketch shows the form of vanes experimented on. The total lift was in all cases 45ft. The inner and the outer diameter of the disc was as 1 to 3—that is, the inlet pipe was 10, and the diameter of the runner 30in., or those proportions. The water rose to this height, but without any discharge, and the wheel required a velocity in feet per second = $\sqrt{2gH}$ with the form of blade A. B required considerably more. C required still more. D required a velocity = $\sqrt{2gH} \times 0{\cdot}82$. This you recognise as not the Rankine curve, but an approximation. D was the best in every respect, and I continue to use it."

I have introduced this matter here to show you how little Appold's curved vanes had to do with the improvement of centrifugal pumps. I will remark that in my own experience the shape of the vanes does not involve a great deal when considered

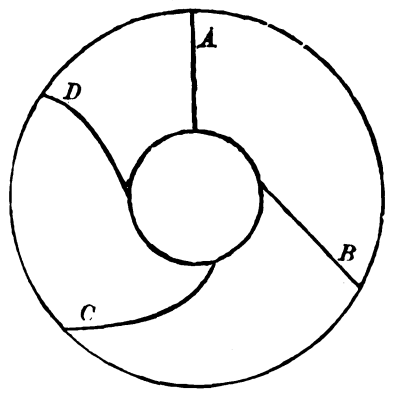

FIG. 3.

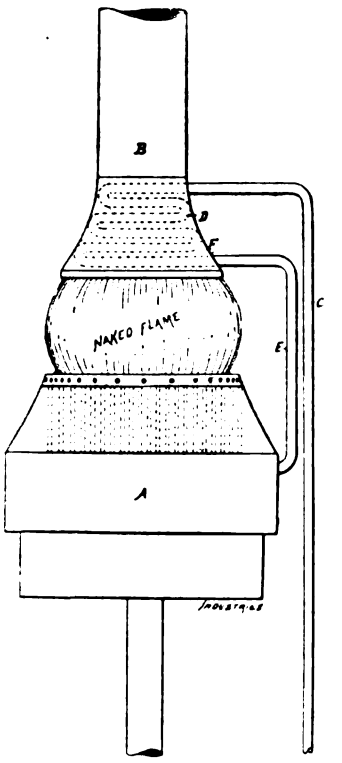
irrespective of the head. If a pump is working against a low head, I think that a flat radial vane is nearly as efficient as a curved one. The greater the speed of the wheel in proportion to the water, the nearer the vanes should terminate in a tangent.

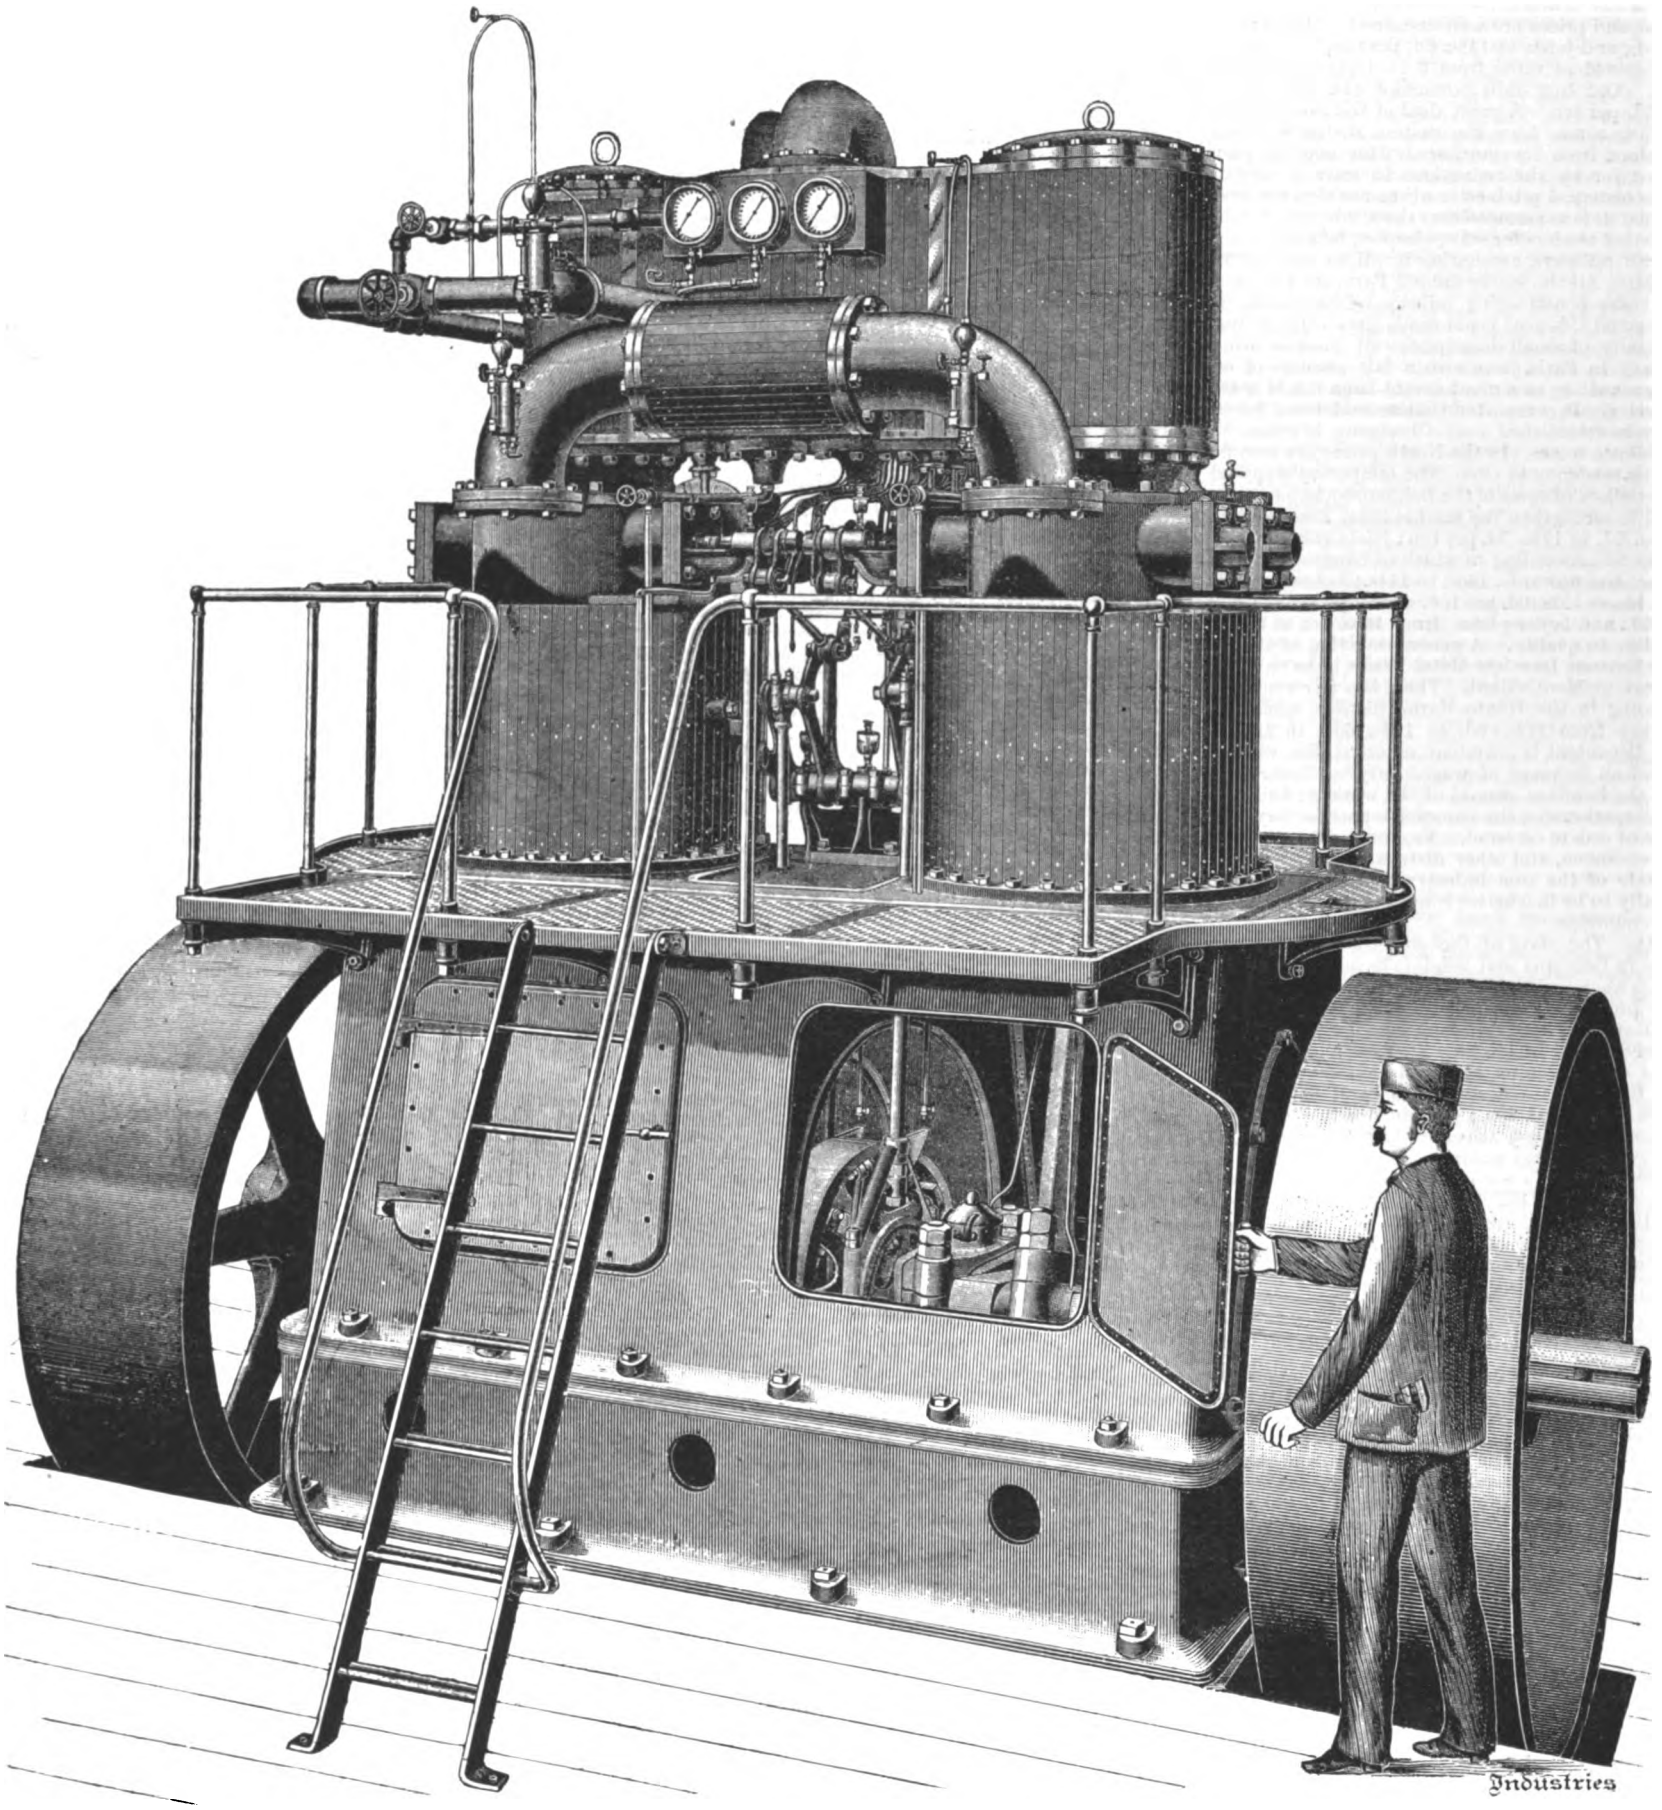


One more point in the history of centrifugal pumps deserves some attention, and that is the experiments of Sir Henry Bessemer, of steel fame. He was, as you perhaps know, for a long time identified with the designing of sugar machinery, and I believe is the true inventor of the centrifugal extracting machine. During his experiments with the extractor in London, he was led to the centrifugal pump. He invented and patented a system of centrifugal-acting pumping machinery, in which he ignored entirely the tangential energy of the water as it leaves the wheel. He thought that was of no use. We have an American invention of the same pumps fourteen years before Mr. Bessemer's. It is shown in Fig. 2, and was invented by Mr. Blake, of Connecticut, in 1831. All that Sir Henry Bessemer did was to modify the pump in various forms—ingeniously in some cases—to be driven by wind, water, or steam. He wrote a long essay upon the subject. His pumps never had much efficiency for low heads; at high heads they might have done very well.

I will remark here that this long and tedious development of the centrifugal pump was characteristic of a past period; such a condition could not exist in our time. If this class of pumps were discovered at this day, they would no doubt receive more development in a single year than in the forty years that is covered by the facts recited. We have a proof of this in dealing with so intricate and intangible an element as electricity. We have seen it, in all of its extensive uses put on a scientific basis, reduced to an exact art within a period of ten years or so.

(To be continued.)

THE IMPROVED "WIGHAM" BURNER.



THE new gas burner illustrated herewith is the invention of Mr. J. R. Wigham, of 33, Capel Street, Dublin, the well-known lighthouse engineer, and is somewhat similar to those already in use in lighthouses. No chimney glasses, liable to breakage, and consequent destruction of the light, are required in connection with this burner. For ordinary or fair weather purposes 28 jets are employed, and these can be instantly increased in number to 48, 68, 88, or 108 jets, as the weather requires it. In the original burner of this description this was accomplished by means of mercurial cups and joints which acted as taps for admitting or cutting off the supply of gas. In the new burner the increase of light, according to the state of the weather, is effected by hollow two-way cocks, to which we shall refer later on. The flame combustion takes place in an atmosphere of air highly heated by the products of combustion, the heat being conducted by the metal work to a chamber F, from which it is in turn supplied to the heart of the burner. The brilliancy of the light is further increased by the use of solid naphthaline placed in a copper receiver A. The flue B, which carries off the products of combustion, is provided at its lower extremity with a bell-mouthed copper chamber F, through which the gas for supplying the burner is caused to circulate by means of tubes C, D, and E, the latter of which conducts the hot gas into the top of the receiver A containing the naphthaline. The hydrocarbon vapour given off by the latter is thereby absorbed by the heated gas, thus becoming enriched prior to entering the burner.

Supposing during foggy weather that the whole of the 108 jets are ignited, and that on the cessation of the fog the 28-jet burner only is required, the arrangement of the hollow two-way cocks enables the light-keeper to reduce in a moment the quantity of carbon necessary for the large burner to that necessary for the proper combustion of the smaller burner. These hollow cocks are in communication with a chamber of cold gas, not enriched, which is drawn upon by a small turn of the cock to the extent required to give the proper illuminating power to the burner. This system is not only effective to the extent explained, giving, we are informed, double the power of the most powerful gas burner now used in lighthouses, but is exceedingly economical, for instead of requiring cannel gas, which is expensive, gas made from ordinary coal may be used. At present, under the gas system of lighthouse illumination, three kinds of coal are used—viz., cannel coal, banking coal for keeping up the heat in the retorts, and house coal for the light-keeper's use; but under this system one kind of coal, Newcastle or Wigan, is only necessary, the coke from which will keep up the heat in the retorts.

TRIPLE EXPANSION ENGINE FOR ELECTRIC LIGHTING PURPOSES.

General View.

TRIPLE-EXPANSION ENGINE FOR ELECTRIC LIGHTING PURPOSES.

The accompanying illustration represents a vertical triple-expansion engine of somewhat novel construction, designed by Mr. S. Wilcox, of the Babcock & Wilcox Company, and A. Goubert, of New York, for electric lighting purposes. The engine has four working cylinders; the two low pressure ones, 33in. diameter, are single-acting, and have fixed above them the high and intermediate pressure cylinders, 13¼in. and 21in. diameter respectively, both of which are double-acting. The admission and exhaust ports of the high-pressure and intermediate cylinders are controlled by piston valves admitting steam at the centre and exhausting at the ends. The steam, prior to its admission into the intermediate and low-pressure cylinders, passes through receivers. Corliss valves are provided for regulating the supply and exhaust in the low-pressure cylinders. The engine has a stroke of 21in., and when running at 200 revolutions per minute, with steam at 160lb. per square inch, it is capable of developing 500 brake h.p. The valve mechanism is arranged internally. The governor, attached to the crank-shaft, has been ingeniously devised, so that while the balls are perfectly free to move the eccentric under normal loads and conditions, the resistance of the valve mechanism cannot react through the eccentric to move the balls. As will be seen from the illustration, the moving parts are encased, light doors being provided in order to enable the attendant to get at the moving parts. The doors are large enough to allow of the removal of the low-pressure pistons. The total height of the engine is 14ft. 4in., and the floor space occupied outside of the fly-wheels is 15ft. by 7ft. 2in. We are indebted for our illustration to our American contemporary, *Power*.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 26th May, 1891.

The Iron Market.—The general demand continues to be good, and prices are well sustained. Bars are quoted at 140s. 6d., and joists at 148s. 6d. per ton, but much business is transacted at rates from 3 to 4 per cent. below these prices. Old iron rails command 84s. 6d., and castings 112s. 6d. per ton. A great deal of the iron lately brought into Paris comes from the eastern districts, instead of, as heretofore, from the northern. This may in part be accounted for by the reductions in railway rates, and the more economical production of the metal in the first-named districts. It is announced that the Minister of Public Works has invited tenders for rails, sleepers, fishplates, &c., for the Corsican railways, amounting in all to over 3,000 tons of material. All the works around Paris are very busy, especially those constructing railway rolling stock, for which the demand this year is unusually great. The shops making a specialty of small descriptions of work, of which there are many in Paris, have also a fair amount of orders on hand, emanating to a great extent from the War Office and Admiralty. It is reported that several blast furnaces will shortly be established near Cherbourg in connection with the Diélette mines. In the North prices are very firm, with a strong tendency to rise. The temporary stoppage, owing to the strikes, of some of the Belgian works has undoubtedly helped to strengthen the market here. Best bars are quoted at 120s. 6d. to 124s. 6d. per ton; joists vary from 124s. 6d. to 128s. 6d., according to width of flanges; puddled sheets of 3mm. and upwards, 140s. to 144s.; below 3mm. in thickness, 148s. to 152s. 6d. per ton. Steel plates are 160s. 6d. to 168s. 6d., and boiler plates from 160s. 6d. to 209s. per ton, according to quality. A general meeting of the Syndicate of the Eastern Districts Metal Trade is to be held on the 30th inst. at Montbéliard. There is a fair amount of business doing in the Haute-Marne district, where prices for bars vary from 124s. 6d. to 128s. 6d. In the Ardennes much discontent is prevalent amongst the workmen, who demand an increase of wages varying from 15 to 50 per cent.; the hands at several of the works in this district are on strike, otherwise the situation is satisfactory, there being plenty of orders on hand. From the Meurthe-et-Moselle, Loire-et-Rhône, and other districts, report speaks well of the state of the iron industry, which at present appears generally to be in a better condition in France than in most other countries.

Coal.—The state of the coal trade is very good; the strikes in Germany and Belgium have caused orders to flow in more abundantly than ever. No augmentation of prices seems probable, but there is no doubt that the present quotations will be maintained for a long time to come.

Copper, Tin, Lead, and Zinc.—The following were the official quotations on the Paris market during the past week for copper:—Best Chilian bars, £56 10s.; ordinary Chilian bars, £54 10s.; Chilian ore in plates and ingots, £56 10s.; and best selected, £58 15s per ton. Tin has undergone an augmentation in price of 20s. a ton on English, and 40s. a ton on other marks. The prices quoted were:—Banca, £101 16s.; Billiton, £99 16s.; Detroits, £98 16s.; and Cornwall, £103 6s. There has been no change in the price of lead, but zinc has improved slightly in value, and raw Silesian was quoted at £25 3s. per ton.

BERLIN, 25th May, 1891.

Import and Export of Iron.—The import of pig iron into Germany during the month of March showed a considerable falling off, which may be accounted for partly by inactivity of trade in Germany, and partly by the fact that Great Britain has little surplus of iron, and that the stocks in that market are steadily diminishing. In the first quarter the import of pig iron amounted to 39,580 tons, against 88,000 tons in the corresponding period of the previous year. The returns for March were made more favourable through the business in rails, of which 4,288 tons were sent to the Netherlands, 5,244 tons to Switzerland, 3,240 tons to Roumania, and 4,934 tons to this district, whilst the export of pig iron was nearly equal to that of last year—viz., 31,273 tons. The export of wrought was very much higher than for some time previous, 1,102 tons being despatched to Italy, 2,006 tons to the Netherlands, 1,589 tons to Roumania, 2,140 tons to Russia, 1,570 tons to Switzerland, 1,515 tons to the United States, and 3,615 tons sent here for other countries. 1,227 tons of wrought iron were despatched to British India, which has hitherto been regarded as an exclusively English market; 135 tons of wire nails, and 89 of hardware were exported from Germany to British India. The export of wire, though fairly satisfactory, was not so large as that during February, which amounted to 15,756 tons. During the first quarter the export of iron wire amounted to 39,576 tons, against 29,767 tons in the previous year. Although this amount is below the average, there is at least a temporary stoppage of the decrease which occurred during last year. During the first quarter 10,496 tons of wire nails were despatched against 8,976 tons in the previous year.

Manufacture of Explosives.—The smokeless powder made according to Nobel's discovery by the Nobel Dynamite Trust Company has been already produced in sufficient quantity for experimental purposes. Extensive works have been erected for producing it in considerable quantities. After the contracts with certain works for the supply of nitro-glycerine had expired at the end of 1890, the company entered into new contracts with other companies. According to the present supply of orders, a good business year may be anticipated. For a long time past the Rhenish-Westphalian dynamite works have been slackly employed, as the demand from South America, especially from Chili and the Argentine Republic, has fallen off, owing to the unsettled state of affairs.

The Coke Industry.—Ninety new coke ovens are to be built this year, in addition to the sixty already existing, at the Egmont Mine, near Fellhammer, in Waldenburg (Silesia), and a chain railway is to be laid between the Egmont and Mayran pits.

Trials of Cement.—According to experiments recently carried out at Moscow, in order to compare the strength of Russian and German cement, it was shown that Russian cement had a strength of 3,000lb. to 4,500lb. per square inch, and Stettin Portland cement from the Delbruck manufactory had a strength of 5,250lb. The trials were made on cement which had been laid two years ago.

VIENNA, 25th May, 1891.

The Iron Market.—After a long period of inactivity, the Austro-Hungarian iron market shows signs of improvement. This may be attributed to the building season being now at its height. The home market is now in a more favourable condition as compared with the foreign market. The rolling mills are well employed at remunerative prices. Iron for building and constructive purposes is in brisk demand, and manufactories of plate and sheet iron are doing a fair business. There has been an advance in the price of tin of 3s. 10d. per 100kgr. The State Railways Company held its general meeting last week, and the report as to its mining works was very satisfactory. The company's coal mines at Brandeisl made an output of 1,165,000 tons, and there was a net profit of £66,295 9s. The iron works of Reschitza and Annina produced 98,285 tons of ore, the largest output yet recorded, and 75,600 tons of pig iron, against 59,000 tons in the previous year. The iron and steel works produced 39,615 tons, an increase of 4,418 tons, and the rolling mills produced 22,000 tons. The profit of this section of the company's works amounted to £81,601. Last year the Vicanna machine works of the State Railways Company built 62 locomotives and 155 waggons, and made a profit of £42,796 12s. The company will pay a dividend of 16s. on each share of £19 8s.

Traffic on the Austrian Railways.—Statistics have been published comparing the traffic in the year 1863 with the traffic in 1890. In 1863 each passenger carriage carried 4,326 persons on an average, but in 1890 it carried 7,063 persons, an increase of 63 per cent. Each goods waggon in 1863 carried 375 tons, but in 1890 it carried 874 tons, an increase of 133 per cent. The following table gives the results for each railway:—

Railway.	Number of Carriages. 1863.	1890.	Increase per Cent.	Passengers (thousands). 1863.	1890.	Increase per Cent.
Northern	386	728	88	1,864	5,783	210
Carl Ludwig ...	104	345	241	329	1,272	286
North-Western	88	122	39	293	1,044	256
WestBohemian	80	108	35	279	788	182
Aussig-Teplitz	20	94	370	161	1,370	751
Bustichrad ...	18	224	1,144	85	1,193	1,303

Railway.	Number of Goods Waggons. 1863.	1890.	Increase per Cent.	Tons (thousands). 1863.	1890.	Increase per Cent.
Northern	5,576	14,106	153	1,647	9,569	481
Carl Ludwig ...	1,484	3,811	157	255	1,407	490
North-Western	480	1,342	179	206	1,368	564
WestBohemian	800	1,439	80	219	1,811	727
Aussig-Teplitz	195	4,784	2,353	390	7,300	1,771
Bustichrad ...	246	5,219	2,021	581	5,296	812

It is evident from these figures that the home establishments for the loan of waggons are doing a prosperous business, and are beginning to increase their stock of waggons, as they ought to have done some time ago, instead of increasing their profit. On comparing the year 1889 with 1890, there is an increase of 17 per cent. on the passengers and 7 per cent. on goods on the Austrian railways. The total rolling stock was as follows:—

	1889.	1890.
Locomotives	3,518	3,732
Tenders	2,862	3,045
Passenger carriages ...	7,269	7,687
Goods waggons	81,630	87,072

BRUSSELS, 26th May, 1891.

The Iron Market.—The disturbed condition of affairs prevents any recovery in the market, and there are few new orders. Constructive works alone are fairly well employed. There is some demand for joists, but not to the extent which is usual at this season. The strikes have been stopped owing to the action of the Central section in Parliament, and there is an evident recovery of the iron and coal market in the districts of Liége, Charleroi, and Mons. There are no important alterations in prices. Joists are quoted at £5 4s.; angles, £5 6s.; sheets—No. 2, £6 4s.; No. 3, £7; No. 4, £9 12s.; foundry pig iron—Luxembourg No. 3, £2 4s. 9d.; Charleroi, £3 6s. 5d.; forge pig, £2 1s. 6d.; red-short iron, £1 19s. 2d. Steel rails, heavy sections, £5; small sections, £5 14s. The Belgian Government is about to award contracts for about 200 railway sidings, at an average price of £13 2s., and 200 crossings, at £9 6s.

The Coal Market.—The stoppage of the production has caused a rise of prices, which has, however, been checked by the import of coal from abroad. Stocks are now almost exhausted, and prices remain as follow:—Coke, 14s. 5d.; small sorts, 9s. 7d.; close burning coke, 8s.; lump coal, 9s. 7d.; steam coal, 11s. 2d.; household sorts, 16s. to £1 1s. 7d. The contract for the supply of coal to the Brussels gas works will be awarded on the 27th inst., the annual consumption of coal amounting to 90,000 tons, with a value of £80,000. Notwithstanding the fact that the town authorities have recently placed an order for 30,000 tons of coal with English merchants, it seems probable that they will continue to invite foreign competition, as they have drawn up conditions of tender with that object. Belgian coal merchants have agreed to demand a remunerative price, which will probably be approved by M. Aerts, the general manager of the gas works.

The Glass Trade.—Attempts are being made by manufacturers to obtain remunerative prices, and a meeting will be held this week in order to come to some agreement. There is some improvement in the demand for imported glass. Prices remain firm without alteration. The market for plate glass is unaltered. There is a fair supply of orders, but no strong demand. The furnaces on the Wilson system are coming into use in the glass districts. These furnaces are intended chiefly for the use of coal of inferior quality. Their management is easy, but it is necessary to regulate the supply of air in order to mix the fuel properly.

Electric Lighting.—The scale of charges for the electric lighting of Brussels is about to be published. This scale has been carefully drawn up by M. Wybauw, who has visited some of the principal towns which are lighted electrically. M. Van Rysselberghe is still trying to bring forward his scheme for the electric lighting of Antwerp, and has obtained the assistance of some eminent engineers. M. Backeljan, however, the chief government engineer in that town, has worked out a scheme for utilising the tide of the Schelde as a motive power in order to provide Antwerp with a system of compressed air at a pressure of six atmospheres, and has asked for a concession similar to that already granted to the Popp system at Paris.

Lavoisier's Medal.—The Société d'Encouragement pour l'Industrie Nationale has awarded its gold medal to M. Solvay for his share in the development of the ammonia soda industry. This medal is only awarded in each sixth year, Ste. Claire Deville, Weldon, and Michel Perret being former recipients. The distinction is the greater as Schloesing, who is usually regarded by the French as the discoverer of this process, is himself a member of the committee.

DÜSSELDORF, 26th May, 1891.

The Iron Market.—The production of pig iron in Germany during the month of April amounted to 354,350 tons. The amount of puddled iron and spiegel iron was 141,321 tons; Bessemer iron, 33,815 tons; Thomas iron, 134,226 tons; and foundry pig iron, 44,988 tons. From January 1st up to April 30th, 1891, 1,404,383 tons were produced. Prices were as follow:—Spiegel iron, £2 17s. 9d.; puddled iron, £2 11d. 11d. to £2 12s. 11d.; Luxembourg iron, £1 19s. 2d.; foundry iron, No. 3, £2 7s.; bar iron, £6 12s. 2d.; ordinary plates, £7 2s. to £7 11s. 9d.; boiler plates, £8 6s. 6d. to £8 11s. 4d.; thin sheets £6 17s. to £7 6s. 11d.

The Coal Market.—In the Rhenish-Westphalian coal market there is a firm and continuous demand, and new orders have ceased to be received at the mines, since the mines are in arrear in working off outstanding orders. The forwarding of coal is proceeding satisfactorily everywhere. Prices are as follow:—Gas coal, 11s. 9d. to 13s. 9d.; coal for coke, 8s. 10d. to 9s. 4d.; lump coal (small), 15s. 8d. to 16s. 8d.; foundry coke, 15s. 8d. to 17s. 8d.; blast furnace coke, 12s. 9d. to 13s. 9d.

Underground Railway in Berlin.—Mr. Poetsch, the eminent mining engineer, has brought forward a project for an underground railway in Berlin. He intends to excavate the sixty entrance shafts by the application of the freezing process invented by himself.

Railways in Germany.—According to statistics recently published the length of the German railways in the year 1889 amounted to 41,793 kilometres, of which 24,968 were in Prussia, 5,421 in Bavaria, 2,380 in Saxony, 1,500 in Wurtemburg, 1,432 in Baden, 1,472 in Alsace-Lorraine, and 4,620 in the other German States.

AMSTERDAM, 25th May, 1891.

A Dutch Exhibition in London.—The success of the various international exhibitions held in the Metropolis during the last few years has suggested the idea of a Dutch Exhibition, and a committee is now considering whether the scheme be feasible.

New Steamer.—The Royal Steamboat Company at Rotterdam has just had completed for its passenger service up the Rhine to Mannheim a new steamer, the "Wilhelmina." It is of the saloon type, and has been successfully launched off the yard of Messrs. Fop Smit, at Kinderdijk.

Digitized by Google

THE TIN TRADE.—The Produce Clearing House at Rotterdam has introduced contracts registration for time bargains in tin, either at Rotterdam or at Amsterdam. Quotations will be settled daily at 2.45 p.m. Four different contracts will be filed, one for delivery of Banca, the second for delivery of Blitong, the third for delivery of Straits tin, and the fourth for delivery of either at the option of the seller. Contracts are for 300 blocks of Banca and Blitong tin, for 10,000kgr. in the case of Straits and combined lots.

THE NEW STEAMBOAT SERVICE BETWEEN HOLLAND AND ENGLAND.—The existence of the Zeeland Steam Navigation Company—which must not be mistaken for the Zealand Steamship Company, whose steamers ply between Queenborough and Flushing—is now fully assured, and the whole capital has been amply subscribed. The service between Flushing and Hull will probably commence on the 1st day of January next. The steamers are being built at Messrs. Dobson's yard in Newcastle-upon-Tyne. Each will have a capacity of about 800 tons, and will be fitted with triple-expansion engines, capable of producing an average speed of more than 11 knots an hour.

NEW INDUSTRIAL REVIEW.—The "Arti and Industriæ" Association of the Hague has decided to publish a quarterly review for the promotion of the interests of industrial art in Holland.

STOCKHOLM, 23RD MAY, 1891.

EXPORTS OF WOOD PULP.—The exports of wood pulp during the first four months of the present year are the heaviest on record. They amount to—

Chemical wood pulp, dry.....	7,346,000	kgr.
Chemical wood pulp, wet ...	3,132,000	"
Mechanical wood pulp, dry ..	7,222,000	"
Mechanical wood pulp, wet ...	4,072,000	"

as compared with an aggregate of 18,437,000kgr. during the same period of 1890, 14,314,000 kgr. in the same period of 1889, and 8,110,000kgr. in the same period of 1888. The exports of matches amounted to 4,295,000kgr., against 3,686,000kgr. in the same period of 1890, 4,109,000kgr. in the same period of 1889, and 3,869,000kgr. in the same period of 1888. The exports of timber were, on the whole, decreasing, as compared with the corresponding figures for last year.

SHIPBUILDING.—The steamer "Wasa" has been thoroughly overhauled at the Finnboda slip, only the old hull, engine, and boiler remaining. The steamer is 183ft. long and 25ft. broad. There is now accommodation for 115 first and second class passengers, of whom 70 are first class. The steamer is intended for the Stockholm, Helsingfors, and St. Petersburg trade. The steamer "Norra Sverize" has been thoroughly repaired at the Bergsund shipyard.

NEW WARSHIP.—The Swedish Government has accepted the tender of the Bergsund Engineering Company for the building of the new warship "Thule" for a sum of £73,611. Offers had also been received from the Matala and the Kockum Engineering Companies, but the tenders from these two firms were at least £5,555 above the one accepted.

CHRISTIANIA, 23RD MAY, 1891.

NEW PAPER MILLS.—The low prices which have for some time ruled on the wood pulp market have led to the erection of manufactories for the further handling of this raw material, more especially for paper making. Another new paper mill is the one projected at Embretsfos, fifteen miles from Drammen, which seems naturally well adapted for cheap paper manufacture. There is an ample supply of timber for wood pulp, and it can be floated direct to the works. There is plenty of water power both for the wood pulp and the paper manufactory, and a dam has been built across the river, having a length of 164 yards and a height of 11 yards. The river carries a volume of water equal to 2,380 cubic yards per second, and, owing to the building of the dam, there is now a direct fall of 17ft. The timber can now be floated straight to the works, entailing an annual saving of £1,100. The present wood pulp manufactory has nine turbines and eight grinding appliances, capable of turning out the very finest wood pulp. The present production is sufficient for two large paper making machines. The annual production of paper for newspaper is estimated at 5,000 tons, and the capital of the new company will be £83,333.

THE NLEFOS-STREUGEN CANAL.—As the works proceed on this important canal, it becomes evident that the original estimate of cost was altogether faulty. In addition to £38,888, by which the estimate had to be increased some time ago, there has been a further increase of £27,555. The cost is expected to amount to £152,000.

MADRID, 25TH MAY, 1891.

AMALGAMATION OF SPANISH RAILWAYS.—The amalgamation of railways causes much excitement, and the question whether there is to be a period of hostility with regard to tariffs on the railway systems controlled by the Rothschilds and the Pereires is much discussed. Possibly there may be an amalgamation of all the Spanish lines. The Government is able to put a veto on the present proposals, as the terms of the concessions do not admit of amalgamation without the consent of the Government. It seems unlikely that the Government would refuse such a demand on the part of the Rothschilds.

THE HERRERIAS SILVER LEAD MINES.—Active progress is being made with the installation of powerful pumping plant for the purpose of clearing the mines in this district of water. Work has been stopped for some years past through the flooding of the mines, and it is expected that the mines will be again in working order in the course of two or three months.

ELECTRIC CABLE TO PORTO RICO.—The laying of an Atlantic cable between Spain and the island of Porto Rico is again under discussion. The Minister for Colonial Affairs has stated in the Cortes that he is considering the conditions on which to invite tenders. It seems that some new cable manufactory has made a proposal with reference to this matter. The contract will not, however, be awarded without an opportunity of competition being given to firms of sufficient standing.

MAIL SERVICE TO THE CANARY ISLANDS.—The fortnightly postal service to the Canary Islands has been given to the Barcelona Company, which has had the contract for some years past. There is a yearly subvention of £9,600. A new steamer of 1,300 tons, with a speed of 11 knots, is to be placed on the service, together with a steamer of 1,100 tons.

LABOUR MOVEMENT AT BILBAO.—After an agitation which lasted for some days, the whole of the miners are now quietly at work again. They seem to have felt that it was against their interests to strike during the period of depression which is affecting the shipments of iron ores. It is stated that the export of Bilbao ore has declined fully one-third during the first four months of this year, as compared with the corresponding period of last year.

FIRE AT THE NERVION SHIPBUILDING YARD.—The sum of £65,000 has been paid by the insurance company in settlement of the damage done by the recent fire in this shipbuilding yard. It seems evident that Sir Charles Palmer is still connected with this business, as he visited Bilbao in order to make arrangements rendered necessary by the fire.

ROME, 25TH MAY, 1891.

MINING IN THE PROVINCE OF CAGLIARI.—During the year 1890 the mines in active operation were 86, of which 75 were lead, zinc, and silver, 2 manganese, 3 antimony, and 6 coal, lignite, &c. The output of these mines in 1890 was in excess of the production of the preceding years, for whilst the total output in the previous campaign had been 144,882 tons, value £666,849, that of 1890 amounted to 149,146 tons, valued at £822,677, thus showing an increase of £155,828 in favour of 1890. This increase is principally due to the greater and more extensive production of zinc (or calamine) ore, antimony, silver, and coal. At the mines 10,301 miners and workmen were employed, of whom 9,479 were males and 822 females.

SALT IN SARDINIA.—The product of the salines in Sardinia amounts to an average of about 115,000 tons per annum, but the quantity of salt made in 1890 was much below the ordinary average owing to bad weather. In the course of 1890 there were 71,278 tons of salt shipped to foreign ports, and 58,874 tons were sent to Genoa, Naples, Leghorn, &c., on account of the Government. By persons who have some experience in the salt trade it is believed that by the fact of the company, which has the working of the salines having undertaken to furnish yearly—from 1891—95,000 tons of salt to the Italian Government, there will arise some little difficulty in obtaining the salt for foreign demands, especially in the year when there is a bad crop; this inconvenience, however, might be avoided by enlarging the area of the salines, and thus increase the product.

ZURICH, 26TH MAY, 1891.

A NEW CENTRIFUGAL FAN.—Mr. Carl Wenner, of this city, has just brought out a new compound centrifugal fan for delivering a high-pressure blast. It consists of three fans, each provided with an annular series of vanes, and mounted so that each series revolves independently of the other and in the same direction about a common axis, but the different series rotate with different angular velocities, which are so related that their circumferential speeds are about equal.

NEW ALPINE RAILWAYS.—A concession has been applied for to enable a railway to be constructed up the Matterhorn, to consist of three sections. Another Alpine railway proposed is the Government Railway, which is a combination of a wire-rope line and rack railway, and is to lead from Riffelalp-Riffelberg to the summit of the Gornergrat (10,286ft.). A third Alpine railway planned in the Canton of Wallis is the Lauterbrunnen and Visp Railway, specially intended for tourists.

UTILISATION OF THE WATER POWER OF THE RHÔNE.—As is well known, the water power of the Rhône is being largely utilised for industrial purposes in the neighbourhood of Geneva. Colonel Turettini, chief engineer of the St. Gothard Tunnel, who carried out the works, has recently issued a report as to the state of the work. The canal on the left bank is provided with 20 turbines, working up to 4,400 h.p. During the past year 216 motors, totaling 1,565 h.p., have been driven from the works. The smallest, of ½ h.p., have been used to run sewing machines, while the largest (625 h.p.) has driven the electric light installation for the town of Geneva.

NEW YORK, 16TH MAY, 1891.

NICARAGUA CANAL.—The party of engineers, including Mr. Warner Miller (president), Mr. Menocal (chief engineer of the Nicaragua Canal), and about twenty engineers and scientists, which went to Nicaragua in April, 1890, to make a thorough investigation of the entire line and to inspect the work already done, returned to New York on the 6th inst. on the United States gunboat "Petrel." The result of the investigation of the line and the work done was entirely satisfactory, and all are thoroughly convinced of the feasibility of the enterprise. The work done is confined principally to the harbour of Greytown, where a breakwater extending 1,000ft. into the sea has been built, so that now there is a depth of water of 14ft. in a locality which was formerly entirely blocked by a bar. The line of the canal has been cleared of the dense vegetation which covered it from Greytown over a distance of ten miles. The company has six large dredges, two of which are at work, and three others will be ready in a short time. The canal has been excavated to a distance of half a mile, with a width of 270ft. and depth of 17ft. The depth is to be increased to 30ft., which is the proposed depth of the canal. A railroad for the transportation of men and machinery has also been constructed parallel with the line of the canal for a distance of ten miles, so that work may be carried on simultaneously at different points along the line. In addition, machine shops and storehouses, docks and wharves, fifty buildings, including offices and quarters, have been built by the company. Mr. Miller expresses himself thoroughly satisfied as to the ultimate success of the enterprise, and believes that the cost will be less than the estimates given.

ARMOUR PLATE EXPERIMENTS AT ANNAPOLIS.—The three days' tests of armour plates at the naval proving grounds have been completed. Three kinds were tried—Harvey nickel, nickel and steel, and steel plates. The steel plates were shattered, the nickel and steel perforated, but the Harvey nickel plates pulverised the projectiles, and were not punctured at all. Each plate had twenty 6lb. projectiles from a Hotchkiss gun fired at it at a distance of 35ft., striking the plate at a velocity of 1,800ft. per second.

RAILROADS.—The big train shed of the Pennsylvania Railroad at Jersey City will be completed in a few days. The span of this shed is 256ft., which exceeds that at St. Pancras, in London, by 17ft. About 6,500,000lb. of iron were used in its construction.

PHILADELPHIA, 15TH MAY, 1891.

BRIDGE BUILDING.—The Philadelphia Bridge Works of Messrs. Cofrode & Taylor, at Pottstown, have recently received a number of large orders. The company is about to build twenty girder and truss bridges on the Port Reading extension of the Philadelphia and Reading Railroad; three large plate girder bridges for the Rome, Watertown, and Ogdensburg Railroad, recently purchased by the New York Central; and three bridges, two of which are to have six tracks, for the Central Railroad of New Jersey. The company has also received orders for new bridges at Trenton, N.J., for the Pennsylvania Railroad, and for a large iron machine shop at Jersey City.

NEW SYSTEM OF ELECTRIC TRACTION.—The Weddell-Enty system of storage battery traction has been tried on the Lehigh Avenue Passenger Railway in this city. The storage battery, which was invented by Messrs. Enty & Phillips, of New York, is radically different from the lead battery of Planté and Faure. The cell consists of a sheet-iron box lined with tin, into which is placed a finely perforated sheet of iron also lined with tin and bent in such a way as to make eight or ten cells. Into this are placed sheets formed of braided copper wire, the interstices of which are filled with oxide of copper. These sheets are coated with a porous coating of cotton to insulate them from the sheet-iron cells into which they are placed. The fluid used in the cells is called "zincate of potash," and is made of the oxides of zinc and potash. A number of zinc plates are then placed in the box. The poles of the battery are the iron box and the copper plates. The first action which takes place when the battery is set up is the reduction of the copper oxide into metallic copper which is of a spongy nature, the oxygen attacks the zinc and the solution is strengthened. When a current of electricity is passed through the cell the solution is decomposed and the action is reversed, depositing metallic zinc on the sheet-iron plate and re-oxidising the spongy metallic copper. On discharging the zinc is again oxidised at the expense of the copper, and thus the secondary current is produced. The cells have a capacity of 500 ampere hours, and each cell weighs 30lb., 100 being required to propel a car at any ordinary speed. An efficiency of 80 per cent. is claimed for this form of storage battery. The dynamo and motor used in the Weddell-Enty system are of the multipolar type, the armature enclosing the field magnets.

DISCOVERY OF A NEW COAL FIELD.—A vein of anthracite coal, 6ft. thick, has been discovered on the Cook Farm, which geologists have claimed to be outside the coal belt. The Lehigh Valley Railroad, which is at present being built towards Dunshore, passes near the new coal field, and another line which has been surveyed also passes close to the Cook Farm. Tunnel Colliery, one of the first to be opened, and one of the oldest in the anthracite region, has been entirely worked out. Until recently, it was one of the most important in the region, employing 200 men and shipping 60 cars per day.

THE "STANLEY" BOILER.

DESIGNED BY MR. H. B. BUCKLAND, ENGINEER, NEWCASTLE-ON-TYNE.

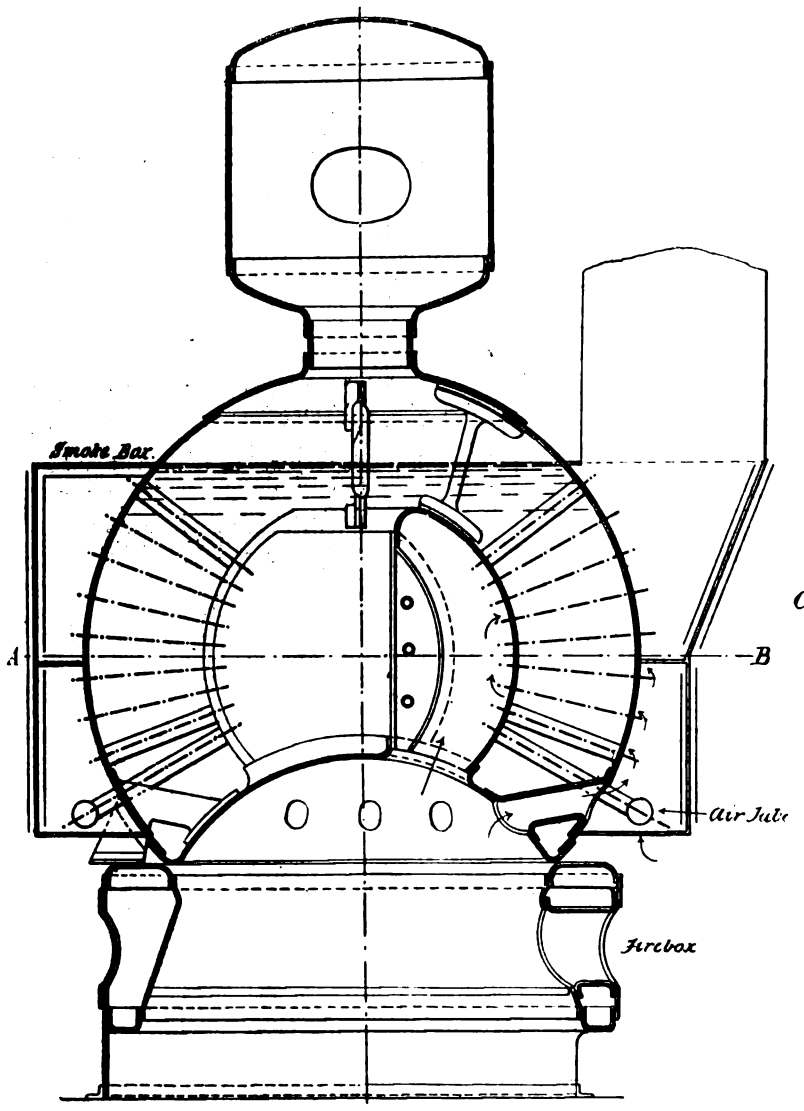

FIG. 1.—SECTIONAL ELEVATION OF BOILER.

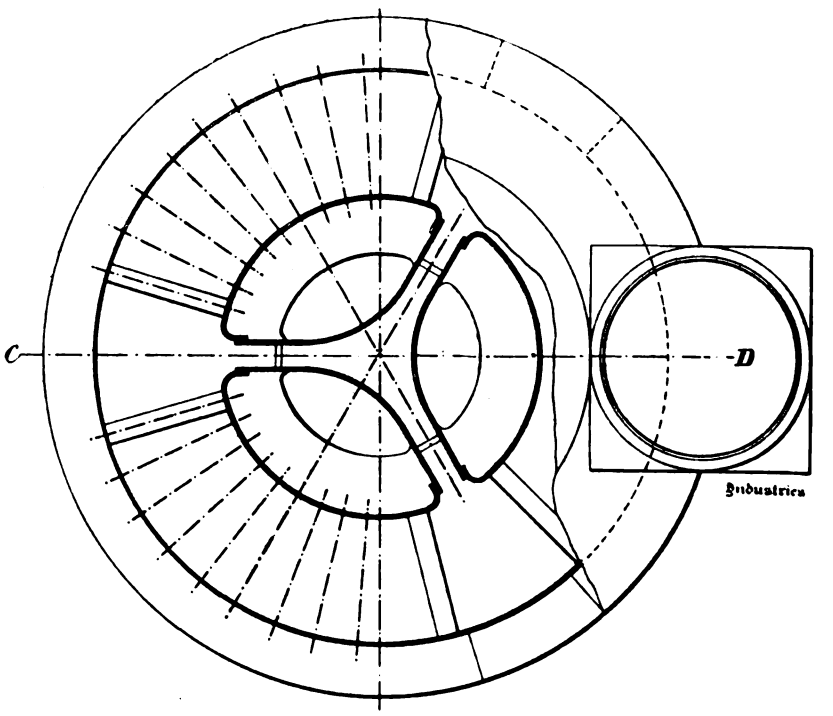

FIG. 2.—SECTIONAL PLAN THROUGH *A B*.

THE "STANLEY" BOILER.

IT is the opinion of many engineers that not much additional progress will be made in marine engineering until a decided advance has been made in the design of the steam generator. With the ordinary multitubular circular boiler the limit of working pressure appears to have been about reached. In fact, to construct boilers of the ordinary design of and over 200lb. working pressure, either the boilers must be small in diameter or excessively heavy in their scantlings. It is not, therefore, surprising to find that attempts are being made to introduce new designs. Most of these do not get beyond the "proposed" stage, but to this the "Stanley" boiler, designed by the patentee, Mr. H. B. Buckland, of Newcastle-on-Tyne, of which we give illustrations in Figs. 1 and 2 above and in Fig. 3 on page 513, is an exception. It will be seen that the "Stanley" boiler is spherical, the lower portion being reversed to form the crown of the furnace, the combustion chambers, three in number, taking away direct the greater part of the gaseous products and passing them through the upper tubes into the smoke boxes, and hence to the funnel. Large lower tubes are also provided in the lower portion of the boiler to take away part of the gases, which are returned through the ordinary tubes into the combustion chamber. The sides of the furnace and bottom are a distinct structure, so that the boiler has practically a "dry-bottom," the lower water spaces forming a feed-heater, any steam generated passing direct through piping to the steam dome or receiver. This arrangement is claimed to be very advantageous, as the sediment deposited in boilers is often mischievous in its action, and in the "Stanley" boiler, as all the feed-water is first passed into the lower structure or foundation of the boiler proper, no deposit is likely to be made in the latter, and it will be much more economical to renew the foundation portion of this boiler than to effect repairs to an ordinary marine boiler injured by overheating of plates, or by pitting, due to feed-water deposits. In any case, it is probable that the longevity of the main portion of the Stanley boiler will exceed that of the present type of marine boilers.

On the 21st inst. the first of these boilers was subjected to an experimental trial, under the supervision of Mr. B. G. Nichol, Newcastle-on-Tyne, in the presence of a number of engineering experts, including representatives of Lloyd's Register of British and Foreign Shipping and of the British Admiralty. Our illustrations represent this boiler, which is 14ft. 3½in. high, 7ft. 6in. diameter, or 8ft. 10¾in. diameter to the outside of the smoke boxes. It contains 252 tubes 2¾in. external diameter, 1ft. 7½in. long, 84 tubes being fitted to each of the combustion chambers. To each of the latter there are also fitted three tubes for admission of air, each being fitted with an apparatus for regulating the quantity admitted. The furnace was bricked round, reducing the diameter of the fire-grate to 4ft. 3in., equal to an area of 14·18 square feet. The chimney, 2ft. 6in. in diameter, 26ft. 4in. high above the fire-bars, is common to all the combustion chambers. The boiler has been constructed by Messrs. J. Eltringham & Co., Stone Quay, South Shields, to the designs of Mr. Buckland, and is constructed for a working pressure of 85lb. per square inch, and has been tested by hydraulic pressure to 170lb. per square inch. The experimental trial was, to suit the convenience of visitors, of short duration—viz., 1⅓ hours—and was primarily for the purpose of testing the amount of evaporation that could be obtained in a given time. The results as to economy of fuel were, as will be seen, not unsatisfactory, having in mind that the boiler was unlagged and not under cover. The trial was carefully carried out; the water was measured by meter; the temperature of the feed (52° Fahr.), taken at frequent intervals, not varying; and the fuel (Davison's West Hartley coal) carefully weighed. The level of water and the condition of the fires was the same at the beginning and conclusion of the trial. The steam evaporated escaped freely into the atmosphere, no pressure being shown on the gauge, and in 1½ hours 4,210lb. of water was evaporated and 537lb. of coal consumed. This is equal to 2,806lb. of water and 358lb. of coal in one hour, or 7·84lb. of water per 1lb. of coal equal to 9·14lb. of water per 1lb. of coal from and at 212° Fahr. The coal actually used was not analysed, but an analysis of coal from the same colliery is as follows:—

Carbon	81·5
Hydrogen	5·2
Nitrogen	1·5
Oxygen	6·2
Sulphur	1·1
Ash	4·5
Total	100·0

This analysis gives a theoretical efficiency of 15·115lb. of water per lb. of coal from and at 212° Fahr.

Reverting to the actual results obtained, it will be found that 197·81lb. of water were evaporated per foot of grate surface and 25·24lb. of coal per foot of grate surface was consumed in one hour, which is in excess of results with ordinary marine boilers under ordinary conditions. The weight of the boiler, including funnel, fire-bars, and mountings, is 7½ tons, weight of water nearly 4 tons, whereas the weight of any ordinary marine boiler of 9ft. 9in. by 9ft., about equal in efficiency, is 12 tons, for the same pressure of steam. At the ordinary pressure for triple-expansion engines—160lb. per square inch—Mr. Buckland estimates that the actual weight of a "Stanley" boiler, without water, and of the same size as that already constructed, would be 8½ tons, whereas an ordinary marine boiler of equal efficiency would be about 17 tons. Probably before long something definite will be known as to the behaviour of Mr. Buckland's boiler at sea, as the one we now describe and illustrate is to be fitted in the steamer "Napier," owned by Messrs. Jas.

Digitized by Google

Wait & Co., Newcastle-on-Tyne, as an auxiliary boiler, being connected to the main engines, and taking the place of the donkey boilers.

Some of the questions to be solved are, Will the boiler prime? is there sufficient steam space? and will the relatively small top surface of the water not lead to considerable ebullition? It appears probable that Mr. Buckland is working in the right direction, and with experience minor improvements will suggest themselves. At the conclusion of the brief evaporation trial the safety valve was set to 70lb., and without forcing the fire this pressure was obtained in twenty minutes, steam having appeared prior to the trial in seventy minutes from starting the fires, so that an hour and a half sufficed to raise steam of 70lb. pressure.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, May 29th, at 9 p.m. Lecture on "An Astronomer's Work in a Modern Observatory," by Mr. David Gill, F.R.S. Saturday, May 30th, at 3 p.m. Lecture on "The Scientific Study of Decorative Colour," by Professor A. H. Church, F.R.S.

BALLOON SOCIETY.—Friday, May 29th, at 8 p.m. Lecture on "Smokeless Fuel," by Mr. J. Coley-Bromfield.

NEXT WEEK.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, June 1st, at 8 p.m. Papers to be read: "Gum Arabic and its Modern Substitutes," by Dr. S. Rideal and Mr. W. E. Youle; "On the Quantitative Analysis of Light and Colour, founded on the Tintometer Colour Scales," by Mr. J. W. Lovibond.

SOCIETY OF ENGINEERS.—Monday, June 1st, at 7.30 p.m. Paper to be read: "Portable and Pioneer Railways," by Mr. John Kerr.

PRICES CURRENT, 27TH MAY, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

THE "STANLEY" BOILER.

DESIGNED BY MR. H. B. BUCKLAND, ENGINEER, NEWCASTLE-ON-TYNE.

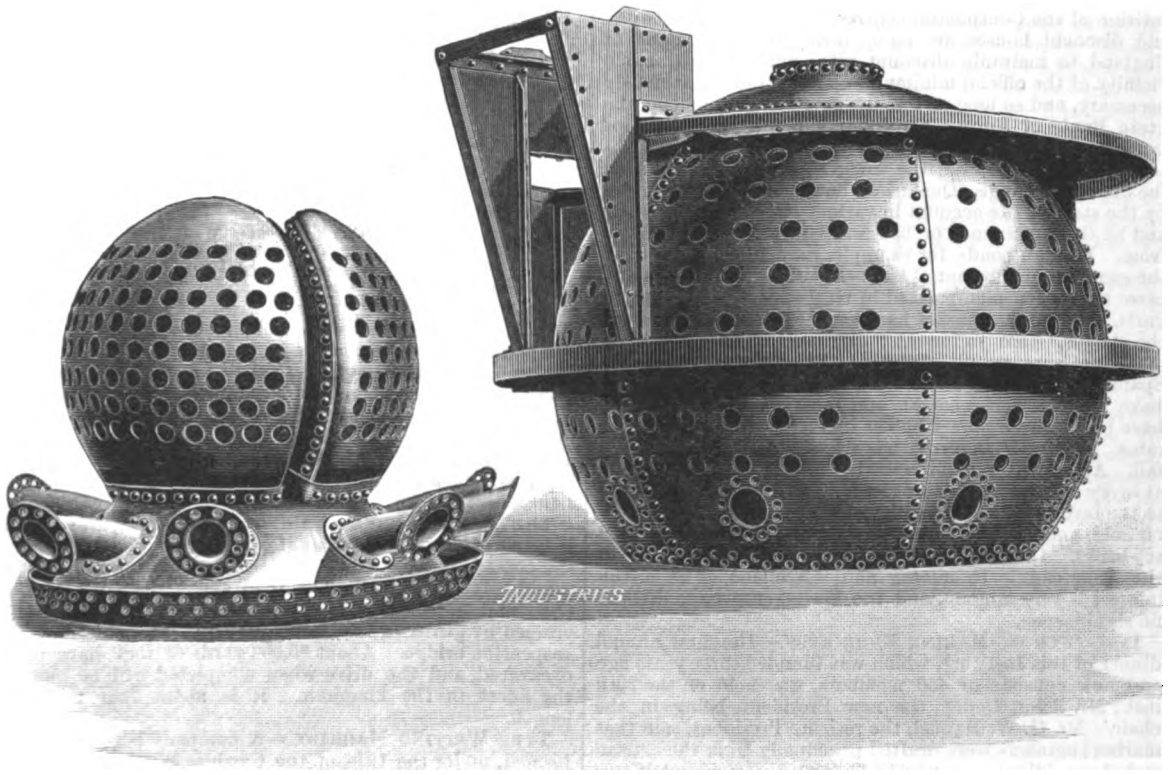

FIG. 3.—VIEWS OF COMBUSTION CHAMBERS AND SPHERICAL SHELL.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER has shown a decidedly stronger tone during the past week. Chili bars have advanced considerably, owing to the scarcity of cash warrants offering and the diminishing stocks. Quotations to-day are £53 15s. to £54 5s. cash, with strong market. Large purchases of Anaconda matte are reported recently, thus reducing stocks. Manufactured firm, at £64 to £64 10s., "strong," according to specification.

TIN: Flat, with tendency to lower prices.

LEAD: Quiet, with values unchanged.

SPELTER is decidedly firmer, and considerable business reported.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Carbolic acids are very sluggish; the production of crude is considerably reduced, but this has no effect upon prices. Benzoles also are quiet. Sulphate of ammonia is again rather easier. Sulphate of copper is a little firmer on spot; higher prices are asked for forward delivery, but there are few buyers. Arsenic, after a rapid decline, is now steady. Borax is firmer. Sulphur is still in short supply.

HOME INDUSTRIES.

LONDON, 28th May, 1891.

The Money Market.—Money continues to pour into the Bank in considerable quantity, and the situation has been greatly ameliorated in consequence. But lest the advantage so gained should be lost through the competition of the Continental centres for the gold, the banks and discount houses are co-operating with the Bank of England to maintain discount rates within a reasonable vicinity of the official minimum. This policy is obviously necessary, and so long as the struggle for gold among the State Banks of Europe continues, a much lower level of rates cannot be looked for here. The settlement has absorbed attention during the greater part of the week on the Stock Exchange. Quotations have been more influenced by the state of the account in various classes of securities, and by the contangoes or backwardations resulting therefrom. Foreign bonds, for example, have been steadied by the exaction of substantial backwardations, which in many cases have been manipulated in view of the settlement in Paris. There the market has been so long influenced by the "bulls," that to reduce "differences" and avoid too much pressure strong efforts are being made to buoy up Spanish, Portuguese, and kindred stocks. Home railways have been dull in general, and most of the movements have been caused purely by the incidence of carrying over rates. Brighton Deferred has been subjected to a heavy fall. Americans remain sensitive and irregular, for while at every opportunity prices rise in Wall Street in response to the favourable local conditions, the continued shipments of gold, and the nervousness so induced, cause repeated set-backs. Canadian railway stocks follow the course of the Americans. In mining and miscellaneous securities interest is very languid, and the movements have little or no significance.

Institute of Marine Engineers.—The first annual dinner of this Institute, which was founded three years ago and now consists of 450 members, was held on the 20th inst., Mr. Peter Denny, the new President, being in the chair. Mr. G. W. Manuel, the retiring President, said that marine engineers were drafted principally from the artisan and the middle classes, who had a fair education, but it was after leaving school that their practical education really began; and it was necessary that during their apprenticeship as engineers, and during their period of servitude as junior engineers, which was the best time for the mind of the young engineer to embrace those higher branches of education which could not be acquired at school, that the practical aid which the Institute was capable of affording should be furnished. Mr. Denny in his inaugural address traced the development of the marine engine from the year 1845, when the consumption of coal, he said, might be estimated at not less than 5lb. per horse-power per hour. A few years afterwards this was reduced to 4lb., and by the reintroduction of surface condensation the consumption fell to 3lb. The corresponding consumption of the compound engine might be put at 2½lb. for some years after its introduction. In 1874 Dr. Kirk designed the first marine engine expanding steam successively through three cylinders. These engines were made by Messrs. John Elder & Co., and fitted on board the "Propontis." They worked at 160lb. boiler pressure, the steam being supplied by a set of the late Mr. J. M. Rowan's water tube boilers. The engines gave every satisfaction, and worked with great economy, but failed to attract the attention they deserved. However, shortly after 1884, the triple-expansion engine became common. With this type of engine and 160lb. boiler pressure the consumption of coal may be taken at 1·7lb. per horse-power per hour. In other words, with triple-expansion engines we get a horse-power for about one-third the coal required in the year 1845. The tendency is still to increase pressures, and Messrs. Denny & Co. have for some years been constructing, both for new vessels and for altering the machinery of old ones, cylinders on the quadruple-expansion principle, expanding the steam successively through four cylinders, with 180lb. boiler pressure.

The Surveyors' Institution.—At the annual dinner of this Institution, held on the 25th inst., the President, Mr. R. C. Driver, occupied the chair, and among those present were Lord Basing, Sir Robert Rawlinson, K.C.B., Mr. P. E. Cunliffe, Sir Henry E. Cartwright, and Mr. E. Ryde, Mr. E. P. Squarey, and Mr. D. Watney, past-presidents of the Institution. Lord Basing said that, as chairman of the Royal Commission on the subject of tithe redemption, he had received much assistance from the Surveyors' Institution. Mr. Squarey said that since 1869 the number of members had risen from 200 to 2,000, and seventeen provincial committees had been formed throughout England and Wales. During the present year seventy candidates out of ninety-two had passed the examinations conducted by the Institution. Sir Henry Cartwright said that the real object aimed at by the Institution was the protection of the public through the formation of an educated body of men as surveyors, and the elevation of the profession. The transactions of the Institution were of much benefit to the younger members of the profession.

The Royal Agricultural Society.—At the fifty second anniversary meeting of this Society, which was held on the 22nd inst., under the presidency of the Earl of Ravensworth, the Earl of Feversham was elected President for the ensuing year. The newly-elected President said that the Society had taken an active part in promoting the many improvements in agriculture which had been made during the past fifty-two years, and had thus benefited the agricultural industries of the country. The half-yearly report showed that the assets of the Society amounted to £35,176 at the end of 1890, as against £38,056 at the end of 1889. The Society's forthcoming country meeting at Doncaster promised to prove of great interest and exceptional magnitude. The total entries of live stock (horses, cattle, sheep, and pigs) were 2,240, as compared with 1,769 at Plymouth, 4,014 at Windsor, 1,875 at Nottingham, and 1,833 at Newcastle. The number of samples analysed in the laboratory on behalf of members from December to the end of April had been 727.

The Institution of Naval Architects.—The gold medal of the Institution has been awarded to Professor V. B. Lewes for his paper entitled "Boiler Deposits," read at the recent meeting.

MANCHESTER, 28th May, 1891.

The Engineering Trades.—Owing to the holidays, which in this district are very prolonged, there is little activity in engineering circles. Business is at a standstill, although most works are well supplied with orders. The complaint is, however, more frequently made that orders are not coming in so rapidly as they were. It is true that there is not yet much room for complaint, but it is significant that the number of firms finding forward work more difficult to obtain is increasing. The tendency towards a quieter state of things is unmistakeable in some directions, but it will be many months yet before it is fully felt in the Lancashire district.

The Marine Drive at Douglas.—The roadway which is being made from Douglas Head to Port Soderick along the coast is making rapid progress, one portion of it being practically completed. The road skirts the edge of the cliff, and in some places is overhanging. Ravines are crossed by girder or trestle bridges, and in one case by a suspension bridge. About 80,000 yards of rock have been excavated, and the drive when completed will be one of the finest in the kingdom. It is about four miles in length.

Type Writing Machine.—A company is about being formed, under the title of the Gardner Writing Company, Limited, to acquire the patent rights of a machine invented by Mr. John Gardner, of Manchester. The machine is of a much simpler character than those ordinarily employed, having but 13 keys, which, however, by an ingenious arrangement, can be made to print 52 distinct characters. The keyboard is entirely within the control of the operator, covering only a small area, and both capital and small letters and figures can be written. The type is formed on a small cylinder of vulcanite, and the letter passes, on its way to take its position, an inking band, after which the paper is pressed against it by a plunger. The strength of the blow on the paper is always even. The alignment is perfect throughout, and the character of the printed letters is distinct and free from blurring. The cost of the machine is low, and as it does a great variety of work it is equal in most respects to the larger machines in the market.

The Linen and Jute Trades.—There was only a poor attendance in the warehouses on the 26th inst., the weather keeping buyers away. Even those who visited the market did not operate freely, and this hesitation was a serious matter for heads of the fancy departments, although the heavier branches were not so much affected. It would appear that during the season heavy goods have sold more freely than lighter makes, both in the home and shipping trades, and, although the new American duties press more severely on coarse fabrics than on finer makes, shipments of the latter have fallen off of late, while those of the first-named articles have increased. The reason for this, it is thought, may be found in the fact that the American market was flooded with the better classes of linens last year, and that there has not yet been time to clear off stocks. Prices of both yarns and cloth keep very firm. There has been a fractional advance in quotations of bleached goods, and manufacturers still express themselves dissatisfied with the rates obtained. On the whole, it may be said of the market that, under the present conditions, it is impossible to speak with accuracy as to the outlook in the home trade, the close of the holidays not being sufficiently remote. There are a few American buyers in Manchester this week. For South America there is not much business.—At the seventeenth ordinary general meeting of shareholders in Messrs. Barlow & Jones, Ld., to be held to-morrow, a dividend at the rate of 10 per cent. per annum will be declared for the half-year ending March 31st. During that period the profits amounted to £20,203. The available balance is £23,463, of which £2,000 is to be added to the reserve, which will then stand at £56,000. The firm's Prospect Mill No. 3 is completed, and the addition to the weaving department at the Cobden Mill is at work.

GLASGOW, 28th May, 1891.

Pig Iron.—Though perhaps it is too soon to say that the reaction after the recent forced advance in prices has fairly begun, the lifelessness which characterised the opening of the warrant market this week would seem to indicate that the iron required speculatively for immediate delivery has all been bought, and that the top of the tide has been reached. The normal demand for trade purposes continues to be sluggish, and the prospective increase in production due to the blowing in of furnaces, owing to the inducement of high prices, indicates a fall. On the other hand, if the warrants now held in London for iron bought at moderate prices before the recent rise be strongly held, the price, abnormal as it is at the moment, may be prevented from breaking for a time. There is, however, the contingency of the market being depressed by speculation as artificially as it has been raised during the past few weeks. The condition of affairs suggests caution on both sides of the account, and buyers and sellers are at the moment reluctant to commit themselves forward. During this week only small parcels of warrants have changed hands. Prices are still firm.

The Recent Railway Strike.—Following the example of the North British Railway, the Caledonian Railway Company has announced certain concessions to their servants. The chief point in the new arrangements is the admission of the principle of the ten hours working day, the system to be carried out so far as practicable. The principle of overtime is also conceded—overtime henceforth to be paid for time above 72 hours per week. For Sunday labour, wages at the rate of time and a half are to be paid. The statement of the general manager also mentioned that the staff of the company had been increased by several hundred men. It is to be hoped that these concessions will conduce to the stability of the relations between the company and its employés.

Miners' Wages.—The wages agitation has so far met with a wholly unfavourable response from the coalmasters. A conference of miners' delegates from Stirlingshire, Mid and East Lothian, and Ayrshire was held at Glasgow on the 25th inst., when it was decided to await the result of further agitation. It has been agreed to contribute to the strike funds of the Belgian miners, who are at present on strike.

Paisley Harbour.—The new harbour in the River Cart at Paisley was formally opened on the 25th inst., on the arrival of the first deep sea steamer which has used the harbour. The vessel was the "Josef," owned by Messrs. Donald & Taylor, Glasgow, which carried a cargo of wood from the Baltic for Paisley consignees.

Paisley Waterworks.—The scheme for supplying the town of Paisley with water from Camphill Reservoir has now been completed, the extension of the reservoir having been finished. The supply is equal to a delivery of 6,000,000 gallons per day. The works were formally opened on the 26th inst. The engineers are Messrs. Leslie & Reid, Edinburgh, and the contractor is Mr. R. B. Stewart.

Business Announcement.—The Patent Sand Moulding Machine Co., Ld., have removed from 95, Bath Street, to Kilbowie Iron Works, Kilbowie, near Glasgow.

(From our own Correspondents.)

LIVERPOOL, 27th May, 1891.

Birkenhead Railway Improvements.—Since the opening of the extension of the joint railway system to West Kirby and Heswall, the traffic has so much increased that further developments of the system have been in progress for some time, and are now nearly completed. From the Green Lane Station terminus of the Mersey Railway the line rises by a steep gradient to the level of the Chester and Birkenhead line, and from this point to Rock Ferry the original railway embankment has been widened by means of heavy retaining walls, and the heavy masonry bridges have been replaced by iron girder bridges of sufficient width to receive the additional lines of rails, the streets underneath being widened. A new station has been built at Rock Ferry, on the north side of Bedford Road. The building is a handsome structure, faced with Ruabon bricks and local red sandstone. The whole of these works have been designed by Mr. R. E. Johnston, the engineer for the joint railways.

LEEDS, 27th May, 1891.

Technical School for York.—The Technical Instruction Committee of the York Corporation have recommended the Council to establish a technical school. It has also been resolved to communicate with the committees of the York Institute and the York School of Art, in order to ascertain how far, and in what manner, either or both of those institutions can be made available in carrying out the resolution.

The Hull and District Institution of Engineers and Naval Architects.—At a meeting of this Institution, held on the 12th inst., for the purpose of electing the officers and council for Session 1891-2, Mr. C. F. Amos was re-elected President. Some discussion took place upon various matters connected with the management of the Institution in the future.

The Campbell Gas Engine.—A repetition order for these engines has been placed by the War Office with the Campbell Gas Engine Company, Limited, Halifax.

SHEFFIELD, 27th May, 1891.

Iron and Steel.—During this week some interesting reports have been issued by local manufacturing firms. Messrs. Wm. Cooke & Co., Ld., of the Tinsley Iron and Wire Rope Works, report a continued and serious fall in the prices of all classes of iron during the past twelve months, and, there having been no reduction in the cost of

Digitized by Google

labour or fuel, the result of the year's working is regarded as unfavourable. There is a net profit of £4,032 13s. 6d.; the profit last year was £10,138. All the reports speak of the reduction in selling values, while fuel and labour maintain their high rate. Prices of raw material are a little higher, especially in the iron trades. The rolling mills are turning out their full capacity of finished material specially adapted to the Sheffield trades. Messrs. Jonas & Colver are laying down plant for rolling their own steel, which is mainly of a special character and for Continental markets. Ordinary merchant iron and steel maintain their price fully, and are ordered freely for immediate consumption.

THE INSULATION OF ELECTRIC WIRES.—Major P. Cardew, R.E., who recently inspected the system of electric lighting in use here, says that the insufficiency of the insulating covering for the wires is a very serious departure from the regulations. He adds that he found a good system of testing was in use, and when the insulation showed any unusual leakage prompt steps were taken to remedy it. The Parliamentary Powers Committee passed a resolution "that all wires for the supply of electric light should be carried underground," which has been forwarded to the Board of Trade.

NORTH STAFFORDSHIRE, 27TH MAY, 1891.

THE IRON TRADE.—There is no improvement to report in connection with the local iron trade, prices showing a weaker tendency. The position is unsatisfactory in view of the high price of raw material. Orders for bars are being accepted at £5 10s. per ton at works, and for pig iron at 42s. 6d. per ton.

THE COAL TRADE.—The cold weather continues, and causes the demand for house coal to be greater than is usual at this season of the year. The prices of manufacturing fuel are weaker, and contracts for supplies over the next twelve months are being entered at prices from 1s. to 2s. per ton below those ruling at this time last year, though there has been no corresponding reduction in the cost of production.

DERBY, 27TH MAY, 1891.

THE QUEEN'S VISIT.—The Mayor of Derby, on whom the Queen was pleased to confer the honour of knighthood in connection with her visit to Derby on the 21st inst., is Sir Alfred Haslam, the inventor and manufacturer of the refrigerating machinery that has practically created a new industry for Derby. Numerous shipping companies, amongst which are the Cunard and the Peninsular and Oriental Companies, are having vessels fitted with refrigerating machinery by the Haslam Engineering Company.

BELLS FOR SYDNEY.—Five bells—one of considerable size—have recently been cast at Messrs. Taylor's foundry, Loughborough, for consignment to Australia. The bells are intended for the Sydney Post Office, New South Wales. The first, second, third, and fourth quarter bells weigh respectively 8½, 11¼, 14¾, and 30 cwt., while the hour bell weighs a little over 5 tons.

CARDIFF, 27TH MAY, 1891.

HEMATITE.—The hematite iron trade shows an improved tone as far as immediate business goes, but buyers do not care to contract for more than a month or two ahead. For steel rails there have been one or two inquiries, quotations for heavy sections ranging from £4 10s. to £4 12s. 6d. Owing to the forthcoming stoppage of tinplate works, the business in Bessemer tinplate bars only covers prompt delivery: prices are quoted nominally at £5 12s. 6d. Shipments of tinplates have been very heavy, dealers apparently using every endeavour to take advantage of the existing tariff. The iron ore market continues strong, and for the better class of Rubio ore prices are maintained at a high level. A few cargoes of second-class ore have been sold at lower figures. Rich manganiferous ore is scarce, and there is not an abundant supply of second class obtainable. Rubio ore, first quality, is quoted at 13s. 3d. to 13s. 6d. c.i.f. Cardiff and Newport, 13s. 9d. Swansea. Imports have been heavy.

COAL AND COKE.—The long continuance of heavy shipments has at last had its effect upon prices, which, after hardening steadily during the month, are now firmly established at about 9d. to 1s. per ton above the value at the commencement of the month. The main reasons for the long existence of such good figures being realised, in face of the depression in such allied industries as the manufactured iron and steel trade and the shipping market, seem to arise from the steady and increasing demand from abroad, together with the proportionately reduced output which colliers choose to supply in times like the present. The question of additional dock accommodation is again coming to the front, and if the present ratio of increase is to be maintained a new dock is an absolute necessity. Prices of steam coal are as follow:—No. 1 quality, 15s. 3d. to 15s. 9d.; No. 2 quality, 14s. 6d. to 15s.; No. 3 quality, 13s. 6d. to 14s. 3d.; No. 4 quality, 13s. to 13s. 3d. Small steam is steady at 7s. to 7s. 3d. f.o.b. There is a better demand for household sorts, No. 3 Rhondda realising 14s. 3d., and No. 2, 12s. 6d. to 12s. 9d. For coke there is more inquiry, and makers are requesting, and to some extent are realising, better prices, on account of the advance in coal. Prices are:—Best foundry, 24s. 6d. to 26s.; foundry, 22s. to 23s.; furnace, 19s. 6d. to 20s. Patent fuel finds a ready sale at 13s. 6d. to 13s. 9d.

BARROW-IN-FURNESS, 27TH MAY, 1891.

HEMATITE.—There is a quieter tone in the hematite iron market, but this is more apparent in prices than in the trade itself. Makers of iron are delivering large parcels, but are confining their make to the output of 39 furnaces, while 38 are standing idle. Last year, in the corresponding week, 46 furnaces were in blast. There is a better prospect of orders from makers of steel and on general foreign account, but the inquiry for forge and foundry qualities, which are mainly required for mixing purposes, is poor. There is still a steady reduction in stocks of hematite warrants. The clearance this week represents from 5,000 to 6,000 tons, and the aggregate of stocks has been reduced to about 140,000. As compared with the statistical position in January of last year, when 380,000 tons of pig iron were held in stock, makers are now in a position to influence the market to a much greater extent than for some time past. Hematite warrants are selling at 53s. net cash, and makers are asking the same figure for mixed numbers of Bessemer iron net f.o.b. The hematite iron ore trade of West Cumberland is very quiet, and the stocks of ore continue to increase.

STEEL.—There is not much life in the Bessemer steel trade, and it is uncertain whether makers will be able to keep their mills in full work throughout the season, as, although orders are fairly held, there is not a prospect of continuous work. Rails of heavy sections are quoted at £4 11s. 6d., light rails at £5 10s., and colliery sections at £6 15s. per ton. In the Siemens-Martin department the only chances of good trade seem to be in the shipbuilding material shops. Plates are firmer at £6 to £6 5s. per ton, and angles at £5 10s., while boiler plates are at £6 15s. Prospects of better trade in shipbuilding material are afforded. Tinplate bars, billets, slabs, and blooms are quiet. Hoops and heavy classes of steel castings are in good demand, and a continuous good trade in the latter departments is expected and practically assured. Messrs. Chas. Cammell & Co., Ld., at their Derwent hematite iron and steel works, Workington, are building the fifth blast furnace, and are stated to intend making spiegel. Hitherto they have bought all their spiegel. Further alterations have been commenced at Harrington Harbour. Messrs. Cammell & Co. are shipping all coastwise steel rails from Harrington.

IRON ORE.—There is a weaker tone in the iron ore trade, and the consumption of raw material is very small compared with the capacity of the mines. Prices are easy at 10s. per ton net at mines for ordinary qualities of metal.

SHIPBUILDING AND ENGINEERING.—The Naval Construction and Armaments Company, Limited, Barrow-in-Furness, have just secured an important order from the Peninsular and Oriental Steam Navigation Company, of London, to build and engine two passenger and cargo steamers of about 6,000 gross tonnage. They will be 385ft. long by 45ft. broad, and 31ft. depth of hold. The engines will be of the triple-expansion type, and develop 2,500 i.h.p. The same company have placed an order with Messrs. Caird & Co., Limited, of Greenock, for two steamers of exactly similar description.

MIDDLESBROUGH, 27TH MAY, 1891.

PIG IRON.—The iron market was thoroughly disorganised yesterday by a resumption of the excitement reported from Glasgow, and a rapid rise in Scotch warrants. When the market opened, 40s. 6d. per ton was asked for No. 3 G.M.B., but when the Glasgow report came to hand sellers raised their rate to 41s., and there were buyers at 40s. 9d., but scarcely any was sold to consumers, the bulk of the sales being to people to make warrants. Over 3,000 tons have been put into Connal's store during the past week. Middlesbrough warrants are 41s. 9d. cash sellers, and 41s. 7½d. cash buyers. Grey forge is quoted at 38s. 6d. by most makers, though in some cases 3d. per ton more has been paid. Local hematite is 52s. per ton for mixed numbers.

FINISHED IRON AND STEEL.—For finished iron and steel the demand is very small, and prospects are not at all encouraging. Common iron bars are £5 12s. 6d.; best bars, £6 2s. 6d.; iron ship plates, £5 12s. 6d.; steel ship plates, £6 2s. 6d.; iron boiler plates, £6 2s. 6d.; steel angles, £5 15s.; all less 2½ per cent. for cash on the 10th of the month following delivery. Puddled bars are £3 5s., and heavy steel rails, £4 10s. net.

SHIPMENTS.—The shipments of pig iron from this port continue satisfactory, 72,062 tons having been sent away this month up to the 25th inst., as against 66,608 tons during the same period of last month. Of the 72,062 tons, 27,078 tons went to Scotland, 7,676 tons to England and Wales, and 37,309 to foreign parts.

WORK AND WAGES.—At a meeting of the mineowners and the representatives of the men an understanding was come to that wages should remain undisturbed until the 6th of July. In consequence of the slackness in the finished iron trade, Messrs. Bolckow, Vaughan, & Co. have given their men at the Middlesbrough and Eston Works fourteen days' notice. This will affect over 1,000 men. The return of the auditors for the Board of Conciliation and Arbitration in the finished iron and steel trades of the North of England, for the two months ending April 30th, has just been published. The result gives, under the sliding scale, a reduction of 3d. per ton on puddling, and 2½ per cent. on all other forge and mill wages, to take effect from the 30th inst. The net average selling price per ton is certified to have been £5 15s. 10d.

SUNDERLAND, 27TH MAY, 1891.

SHIPBUILDING AND ENGINEERING.—There is no improvement in the prospects of these industries. Messrs. Short Bros., Pallion, have sold a steamer of 4,600 tons gross register, which has been built on their own account, to a Belfast firm. The General Council of the Amalgamated Society of Engineers is at present holding its meetings here, and the members take the opportunity of visiting the various shipbuilding and engineering establishments. To-day Roker Pier and the docks were visited. At present the iron gates for the No. 2 Entrance, which were constructed in 1848, are under repair. These gates are nearly 100 tons in weight.

SHIPPING.—Freights have not improved either outwards or homewards, and Black Sea rates have fallen. It is difficult to obtain satisfactory fixtures for prompt vessels, but for August 4s. from New York to Cork for orders is obtainable. The returns of the River Wear Commissioners for April are the most satisfactory of the present year. The coal shipments amounted to 358,880 tons, as compared with 305,975 tons in April, 1890, an increase of 52,905 tons. The revenue from every source but the goods traffic showed an increase, the total being £11,469 14s. 1d., an increase of £978 12s. 5d. Owing to the Whitsuntide holidays last week's coal shipments were only 56,130 tons, a decrease of 27,285 tons as compared with the previous week.

MARINE ENGINEERS.—A conference of shipowners and representatives of sea-going engineers belonging to the ports of Newcastle, Hartlepool, Middlesbrough, and Sunderland has been arranged to meet here on the 8th prox. to settle mutually a uniform scale of wages.

NEWCASTLE, 27TH MAY, 1891.

THE COAL TRADE.—The demand for steam coals is still satisfactory, and there is also a good deal of inquiry respecting gas coals for exportation. Owing to the continuance of cold weather, household coals are in better demand than is usual at this time of year, but sales of bunker coals continue limited. The shipments of coals and coke at Tyne Dock for the week ending the 23rd inst. amounted to 99,534 tons, being a decrease, as compared with the corresponding week last year, of 13,964 tons. This large decrease is doubtless attributable to the intervention of the Whitsuntide holidays.

ENGINEERING.—The dispute between the fitters and plumbers at the Palmer's Engineering Works, Jarrow, is still unsettled, and its continuance is causing much inconvenience to the employers. Messrs. Hawthorn, Leslie, & Co. have since the beginning of the month sent away from their St. Peter's Works large quantities of sectional parts of engines, which are to be fitted in vessels recently launched from Government dockyards. Messrs. Clarke, Chapman, & Co. have just completed a contract for the manufacture of a new and interesting specialty required in the equipment of telegraph cable ships. It is the invention of a gentleman connected with the Eastern Telegraph Company, and is said to be a great improvement upon contrivances of a similar nature that have hitherto been in use. In the locomotive engineering shops there is a fair amount of activity, the works of the North-Eastern Railway Company at Gateshead being particularly brisk.

ELECTRIC LIGHTING.—Messrs. J. H. Holmes & Co., electric lighting engineers, continue extremely busy with steamship installations, and have several vessels in hand on the Tyne, Wear, Clyde, and Mersey. Some of the foregoing are passenger vessels of a first-class type, and one is fitted with no less than 200 incandescent lamps, Suez Canal projector, and arc lamps complete, to meet all requirements of the Suez Canal Company. Among other contracts now in hand are three portable electric lighting sets for different Suez Canal companies. These plants are light, well made, simple, and easy to manage, and are in great request by the engineers of vessels passing through the canal. Messrs. Ernest Scott & Mountain, Ld., are also busy in their electrical department, among other contracts now in hand being a large installation of between 600 and 700 lights for a Glasgow firm, and one for a bondage store in Leith. The firm have just completed an important installation on a Sunderland built steamer.

THE MELINITE AFFAIR.—Messrs. Armstrong, Mitchell, & Co., Ld., have made the following statement with regard to the melinite affair:—"Certain negotiations were entered into between M. Turpin and the Elswick Company for the use of an invention relating to explosives which M. Turpin expressly stated he was at full liberty to sell. Whatever technical information the Elswick Company acquired was given, not by M. Triponé, but solely and directly by M. Turpin, who represented that he was perfectly free from all obligations in any quarter. No experiments carried on by the French Government were ever communicated, either by M. Triponé or M. Turpin, to Elswick."

SHIPBUILDING.—Messrs. Armstrong, Mitchell, & Co. have just put down the keel for a large cruiser ordered by a foreign Government, and the work of this vessel will, with the other work in hand, keep the yard moderately busy for some months to come.

THE "PERRY" ENGINE INDICATOR.

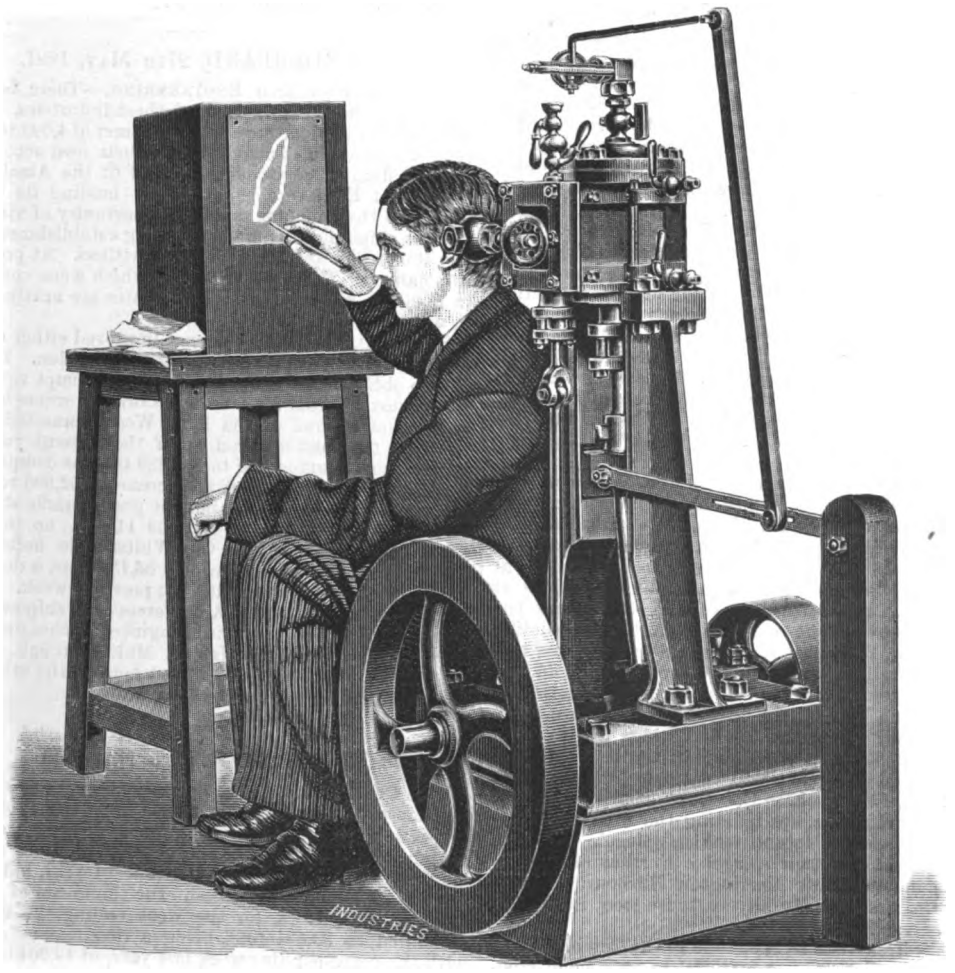

Fig. 1.—General View of Indicator in Working Position.

THE "PERRY" ENGINE INDICATOR.

To some engineers the accuracy of the ordinary engine indicator is a sort of faith; others are, however, a little sceptical. In 1885 Professor Osborne Reynolds read a paper at the Institution of Civil Engineers which did much to disturb our confidence in the general accuracy of indicator diagrams. In it attention was called to several serious sources of error, such as inertia of the moving parts; friction of the piston and the pencil gear; backlash and "give" in the pencil gear; temperature variations in the springs; inaccuracy in the springs; long and tortuous

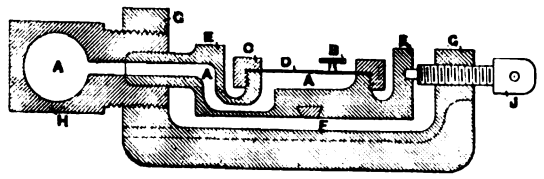

Fig. 2.

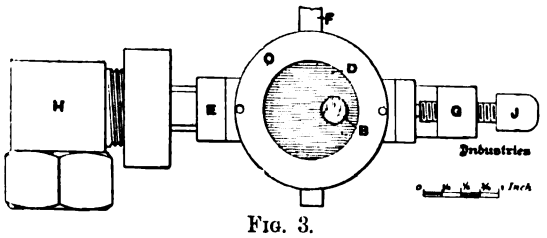

Fig. 3.

steam connections; stretching of the string; and want of correspondence between the motion of the paper and of the engine piston. These disturbing elements give rise to very large errors, and even if we do not estimate them so high as Professor Reynolds, it must be admitted that the steam engine indicator, with the usual arrangements for giving motion to the barrel, is not an extremely accurate instrument, even in its most improved form.

Apart from these features of inaccuracy the engine indicator is, after all, a roundabout sort of instrument to get a desired result. If an engineer wants to know the pressure in a boiler, he looks at a direct reading gauge; but if he wants to know the power developed in an engine, he fixes on an indicator, but this does not show the power at once. The engineer has probably to climb about to fix his indicator on the engine cylinder. If the engine be in a ship, and there is a big sea on, the experimenter in taking a diagram may tear several cards, and probably burn his fingers, and in some cases run a chance of being killed. After all this he has not got the horse-power result, but merely a diagram. Additional observation of the speed must be taken, and the area of the diagram must be measured with a planimeter or other means. After doing all this, a result having some sort

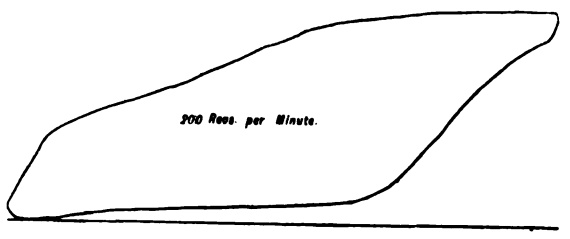

Fig. 4.

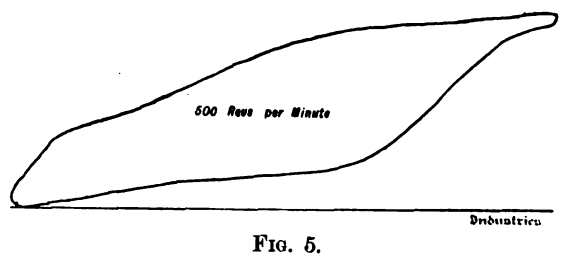

Fig. 5.

of relation with the power in one end of one cylinder is obtained, and several more operations, with their accompaniments, give the final results.

Professor J. Perry, F.R.S., of the Finsbury College, has set to work to improve these roundabout methods, and has produced the very simple and ingenious form of indicator, which we illustrate in Figs. 1, 2, and 3. The piston and cylinder are discarded altogether. Instead of them there is a thin steel drum-head D. The pressure in the box A bulges the disc out a little, like the disc of an aneroid barometer or Schäffer-Budenberg gauge. A mirror B is set about half-way between the centre and the edge. The pressure thus bends the disc and deflects a beam of light in one direction. The drum is moved in another angular direction by means of a lever F, and this moves the spot at right angles to the pressure direction. The result is that the spot traces a true diagram of the working of the engine. The steel disc is so light and strong that its period of vibration is too high for its inertia to affect the diagram, not only of a marine or mill engine, but even to make a perceptible difference on a locomotive, a small gas engine or a high-speed electric light engine. The barrel cord is entirely superseded by a rigid rod or connection which does not admit of stretching or backlash.

The diagram formed by the instrument may be made permanent, as it can be traced over with a pencil. An oil lamp, with a large mirror, gives a very good "spot," and even at the slow speed of 60 revolutions it is easy to trace the form of the diagram. For many purposes, however, a record is not wanted. With the "Perry" indicator the engineer may not only have the water, boiler pressure, vacuum, and other gauges in front of him, but he may have a visible indicator diagram also. He has not to perform a series of operations whenever he wants to know what is going on inside the cylinders of his engine, and he can watch the effects of any alteration of boiler pressure, or of the valve gear, without difficulty or trouble.

Professor Perry read a paper on his indicator at the Physical Society on the 22nd inst., and showed a number of diagrams taken by Mr. Holland, who has been engaged in working out some of the details. Fig. 1 shows a general view of the indicator as attached to a small engine, Fig. 2 is a longitudinal section, and Fig. 3 a plan of the instrument. Figs. 4 and 5 are specimen diagrams taken with it, which were photographed by the light of an oil lamp, after about a minute's exposure.

ROYAL STATISTICAL SOCIETY.

At a meeting of this Society, held on the 26th inst., the President, Dr. F. J. Mouat, F.R.C.S., LL.D., in the chair, a paper was read by Dr. Venn, of Caius College, Cambridge, on "The Nature and Use of Averages."

The general object of the paper was to show that the prevalent habit of almost implicit reliance upon the common arithmetic mean or average of a number of magnitudes, perfectly justifiable as it is in many cases, needs some revision and caution.

Three classes of cases seem to deserve prominent consideration:—1. If we are only concerned with comparative results—and these presumably form the bulk of ordinary statistical inquiry—then almost any kind of average will answer the purpose. That is, the order of arrangement of a number of groups of things, and the question whether these groups are increasing or diminishing in respect of any particular characteristic, are hardly at all affected by the particular kind of average we may choose to employ. 2. If we want accurate quantitative results, then the selection of the kind of average is no longer at our own disposal, but must depend upon the precise object we have in view. The common arithmetic mean *may* be the best, and probably in most practical cases is so, but circumstances can easily be suggested in which some other kind of mean becomes, not merely more convenient, but distinctly more accurate. 3. There is the well-known class of cases—of which the science of mensuration offers the most familiar examples—in which the mean is resorted to in order to discover what is regarded, actually or metaphorically, as the true value. The suggestion is offered that it may depend upon the object we have in view, not merely what kind of average should be selected, but whether there is a necessary gain in employing one at all. We start with a set of discordant values. By taking an average of any number of these, all that we get is a specimen of what is generically of the same kind, though specifically of a better sort. In it, broadly speaking, great errors are less common, and small errors are more common. In the majority of cases this is an unmistakeable gain, but in exceptional cases there may be no gain, or even actual loss.

When, indeed, the "true value," at which the aim is supposed to be directed, becomes purely metaphorical—as in the curve of mortality—it becomes a question whether the resort to a single mean or average is not, for some purposes, not only unsuitable but actually misleading. When the curve of error, instead of being so arranged that the arithmetic mean corresponds to the most frequent result, presents itself in a one-sided form, or still more, in a hump-backed or double-backed form, the common average loses most of its significance and importance. The mere assignment of the average, by itself, may misdirect the attention from some of the most important characteristics of the phenomena.

A discussion followed the reading of the paper.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 399, Strand, London, W.C.*

FRIDAY, 29TH MAY, 1891.

THE USES OF PETROLEUM IN PRIME MOVERS.

THE interesting and valuable paper on the "Uses of Petroleum in Prime Movers," recently read before the Society of Arts by Professor Robinson, seems to open up a new field in the economical development of prime movers, and although the opinions expressed may in some cases have been a little too optimistic, and founded on the results of experiments which require to be verified, they deserve the careful attention of engineers and of power users. The paper contains a great deal of information with regard to the properties of petroleum, which is very valuable, but into this our present space will not allow us to enter. A few particulars, however, of special interest to engineers, may be noted. The first use of petroleum in prime movers is as a substitute for gas in the internal combustion engine. Here the heat, generated by the combustion of a mixture of oil vapour and air inside the engine cylinder, is used directly to expand the products of combustion, and so drive forward the piston. Professor Robinson is of opinion that, just as the "Otto" gas engine, in the hands of Messrs. Crossley Bros., in this country, has been developed into a reliable and useful prime motor, so to Messrs. Priestman Bros. is due the credit of the further development of the gas engine into the common oil engine, which has now established itself as a still more useful and popular prime motor, since its fuel—ordinary lamp oil—is to be had in every village, and the engine itself can be looked after by unskilled hands. Its record has been so satisfactory that it even excels the parent gas engine in replacing small steam engines, and it is to be found doing good work efficiently at coal and other mines, and lighthouse stations. We need not, in the meantime, go into the details of the action of the engine, as no doubt these are known to many of our readers. We may mention, however, some of the results of experience. Taking an engine of 5 h.p. nominal, having a cylinder 8½in. diameter and 12in. stroke, the compression before ignition is found to be 33lb. per square inch, and the mean pressure throughout the stroke 54·4lb. The speed was 180 revolutions per minute, the air pressure 10lb. per square inch, and the brake horse-power 7·06. The measured oil consumption was 0·85 pint per brake horse-power per hour, and taking this at 5½d. a gallon—the price charged by the American Oil Company—the cost of an actual brake horse-power by this small engine is about a halfpenny per hour, while larger engines give still greater economy. In a still smaller engine, of 1 h.p. nominal, the horse-power actually developed was, on an average, 2·5, with a consumption of 1·07 pint per actual horse-power per hour. Engines of this kind are now being introduced to a considerable extent into all kinds of industrial works, and have been found to be convenient and trustworthy for electric lighting. Mounted on wheels they become useful for agricultural and many other purposes, and they invariably receive an excellent character for their steady and trustworthy running, proving themselves to be the best of their kind hitherto in the market.

Another form of engine described by Professor Robinson was the "Ackroyd" oil engine, which differs considerably in its action from the "Priestman" engine, but which promises well to contest the field with it. In the case of an engine developing 7·6 h.p., the oil consumption was found to be less than a pint per brake horse-power per hour. The oil used was of specific gravity ·854, and was very much like the Scotch intermediate shale oil, but heavier oils might be tried without disadvantage. The "Knight" oil engine, which has been in use for several years, has several novel features in its construction. It is of the three-cycle type, like the "Griffin" gas engine, and has a high piston speed, 300 revolutions per minute, with a 9in. stroke. The ordinary Russian kerosene oil is used, and the consumption is stated to be only a small fraction of a gallon per brake horse-power in actual work. For large powers it is now being generally recognised that the ordinary vaporisers in petroleum oil engines are difficult and troublesome to work with, and that the most practical plan is to convert oil into gas by means of a gas producer. Oil gas, when cooled, can be used with great economy in the engine cylinder, and it is found that a very decided saving in fuel may be effected by the combination of an oil gas producer with the internal combustion engine, in place of the boiler and steam engine, in many places where suitable oil is cheap or plentiful, or where intermittent work is required. On the other hand, more heat may be produced by the direct combustion of liquid fuel with dry steam and air, than by first converting the oil into gas before using it as a fuel. Oil gas is now generally made from Scotch intermediate shale oil, partially refined petroleum, mutton fat, waste grease drippings, and such like heavy oils and fats as are not available for use in the ordinary oil engine cylinder, and may be had at low prices. Various forms of gas producers have been used. Professor Robinson described those designed by Mansfield, Keith, and Thwaite, and pointed out the special uses and advantages of each.

But neither petroleum nor gas engines are likely, at least in their present shapes, to supersede steam engines, and hence one of the most important uses of oil is as liquid fuel for steam raising purposes. Mechanical engineers are well acquainted with the work of Mr. Thomas Urquhart in Russia, in which he has used very efficiently the heavy residuum from petroleum. The quality of this is very good, and rich in heating power. Mr. Urquhart found that whilst the maximum evaporation with this residuum, from theoretical calculation, was 17lb. of water per lb. of petroleum, he could get an evaporation of 14lb. in his locomotives, or 82 per cent. of the total possible evaporation. In this country we have neither had the opportunities nor the necessity for the extensive use of liquid fuel, as coal has been so cheap and plentiful, but still sufficient experiments have been made to show the importance of the matter. Mr. James Holden, locomotive superintendent of the Great Eastern Railway, has been making some experiments, and of the results of these Professor Robinson gives an abstract. If we could depend absolutely upon their correctness, they would be very satisfactory indeed. In using liquid fuel various forms of injectors are used for atomising the heavy liquids into spray, and burning them in a furnace. Of these the best known in this country are those designed by Thwaite, Holden, Bray-Smith,

Digitized by Google

and Henwood, all of which were described by Professor Robinson. According to Mr. Holden's experiments the following is a statement showing the comparative consumption of fuels in stationary boilers and locomotives with coal, and liquid fuel with coal—the coal used for lighting up being included in each case. In a small Cornish boiler, when fired with a given coal alone, the consumption was 121·3lb. per hour, and when fired with liquid fuel and coal, the consumption was, liquid fuel 35·1lb., coal 19·2lb., and coke 14·7lb., or a total of 69lb. per hour—a little more than half of the weight of the coal when used alone. With a vertical boiler the consumption, when fired with coal alone, was 77lb. per hour, but with liquid fuel and coal this fell to 38lb. of liquid fuel and 10lb. of coal, or a total of 48lb. of coal per hour. With a stationary boiler of the locomotive type, when fired with coal alone the consumption was 275·1lb. per hour, while with liquid fuel and coal the consumption was, liquid fuel 99·3lb., coal 101·8lb., or a total of 201·1lb. per hour. With an express engine with 7ft. driving wheels, cylinders 18in. by 24in., burning liquid fuel and coal, it burnt, liquid fuel 10·5lb., coal 15·0lb., or a total of 25·5lb. per mile, while the average consumption of coal on nine engines of the same class is 34lb. per mile.

These are remarkable figures, but, like Professor Unwin, who took part in the discussion, we have our doubts as to their correctness, and believe that the calorific effect of petroleum is over-estimated. In fact, the results of all experiments connected with evaporation require to be received with very great care, for they depend to a great extent on the conditions of the boilers and of the steam generated. This is a point to which we would direct the attention of the Research Committee of the Institution of Mechanical Engineers, as there can be no doubt that the use of petroleum in prime movers, either directly or indirectly, has a great future before it, and is likely to have considerable effect on the development of motors of different kinds.

BOILER DEPOSITS.

As we briefly announce in another column, the gold medal which was promised by the Council of the Institute of Naval Architects for the best paper read at the late meeting, by any one who was not a Member of the Council, has been awarded to Professor Vivian B. Lewes, F.C.S., F.I.C., of the Royal Naval College, for the paper read by him on "Boiler Deposits." As we reprinted the paper in full (see *Industries*, Vol. X., page 363), we need not enter into a detailed account of its contents, but in view of the fact that it has been specially marked for honour by the Council of the Institute of Naval Architects, some of its chief points may be noted, and probably discussed by our readers, for it does not follow that Professor Lewes' conclusions will be unanimously agreed to. Until recently the deposits taken into consideration have been those formed from the impurities natural to the water itself; but with the introduction of high-pressure steam a new and highly dangerous form of deposit has been added to the trouble of the marine engineer. After the collapse of the furnaces of certain steamers in 1878, and that without any apparent cause, attention was paid in marine circles to the action which had taken place. The only clue to be found was that a certain amount of oily deposit had formed on the tops of the furnaces, and experiments made by Mr. Dunlop, of Port Glasgow, led to the conclusion that this oil, which had distilled into the boiler from the lubricants used in the cylinder, was so bad a conductor of heat that its formation on the plates allowed them to get superheated, with the result that they were unable to withstand the pressure of steam existing in the boiler, and in this way brought about the collapse. Similar cases of collapse became frequent after that date, no less than thirty vessels being disabled from this cause during the last few years. In his paper Professor Lewes gives an account of a number of experiments and tests with boilers in order that he might arrive at the cause of these collapses, and his work should be carefully studied by marine engineers. They show that a deposit is formed by the combination of the oil with the solid particles of calcic carbonate, calcic sulphate, &c., and that the effect of the oil on the particles is to cause them to rise and fall with the convection currents which are going on in the water, and to stick to any surface with which they come into contact. In this way they deposit themselves, not as in common boiler incrustations, where they are chiefly on the upper surfaces, but quite as much on the under sides of the tubes as on the top, their position being regulated by whether they come in contact with the surface whilst descending or ascending. The deposit so formed is a wonderful non-conductor of heat, and Professor Lewes attempted to determine the effect which it had in allowing excessive heating of the plates to take place, and in retarding the heating of the water. He found that, with the fierce heat existing in the boiler furnaces, given an oily deposit of only $\frac{1}{16}$in. in thickness, the plates will readily be heated to a temperature at which they are totally unable to withstand a pressure of 80lb. of steam, and collapse of the furnace crowns must follow.

Professor Lewes gives some useful information regarding the properties of good lubricating oils, and points out that the great advantages of a good mineral oil cannot be too strongly insisted on, and that any lubricant containing animal or vegetable oils to give it "body" should be unhesitatingly discarded. He also gives instructions for the precipitation of the impurities usually found in the water of marine boilers, for details of which we must refer to the paper. The whole subject, however, is one still requiring further elucidation, and we shall be glad to have the opinion of some of our readers regarding it.

"THE BUILDING OF THE SHIP."

Under the above title the Fairfield Shipbuilding and Engineering Company have printed for private circulation (partly reproduced from our contemporary, *Engineering*) a most interesting account of the development of the large concern which now belongs to them, and which records the achievements of Randolph, Elder, and Pearce, the men who were most effective in promoting that development. Such publications will be of the greatest possible service to the future historians of engineering, for they supply the materials which are necessary for their work, and data on which to generalise. Those who are at present responsible for the works seem to be animated with the spirit of their predecessors, for they are not inclined to consider even the possibility of decline, and say that "it is enough for them to realise that they are within the influence of one of the most vigorous forms of modern industry, glorying in its strength, and ever extending its dominion. Only half a century has elapsed since the main lines of its structure were reached. Genius and enterprise have guided its growth. Never failing to anticipate the requirements of progressive society, and often directing that progress, those to whom the prosperity of Fairfield Works is due have demonstrated, in a manner that overcomes all crazy theory, the power which well-directed capital can wield as an instrument for general good, and the command over the rude forces of nature, which men of pre-eminent ability, industry, and worth can reach."

The immense establishment at Fairfield had its origin on the 30th of September, 1834, in a small millwright's business, which was started in Tradeston, then one of the suburbs of Glasgow, by two skilled workmen, Mr. Charles Randolph and Mr. R. S. Cunliff. For eighteen years the work was carried on in a very modest way, till, in September, 1852, a new era in the firm's history commenced, when Mr. John Elder became a partner, the style being changed to Randolph, Elder, & Co. It was with the accession of Mr. Elder that the firm commenced the construction of marine engines. Two years later it started to make boilers, and six years afterwards, in 1860, shipbuilding was added, less attention being henceforth given to millwright work. The firm latterly confined itself to the more important and probably more remunerative branches of industry, and the fame achieved as shipbuilders and marine engineers is conclusive proof of success. In order to meet the growing demands on the firm, the ground at Fairfield was acquired and laid out in 1864 by Mr. John Elder, with a forethought for the requirements of succeeding years which his successors have not failed to appreciate. In the year 1868 Mr. Randolph and Mr. Cunliff, the two original partners, retired from the concern, Mr. Elder remaining the sole proprietor of the business until his widely regretted death, at the age of 45 years, in London, in 1869. His executors carried on the undertaking for a few months, and on the settlement of affairs the style of the firm was altered to John Elder & Co., the partners being Mr. J. F. Ure, Mr. J. L. K. Jamieson, and Mr. (afterwards Sir) William Pearce. Nine years later, in 1878, the latter gentleman became sole proprietor. In 1885 Mr. Richard Barnwell was accepted as partner, and in the following year the firm was converted into a private limited company, under the title of "The Fairfield Shipbuilding and Engineering Company, Limited." In 1887 Mr. Pearce, who had meantime entered Parliament as member for the Govan Division of Lanarkshire, was created Baronet in recognition of his distinguished services in connection with the naval and mercantile marine. This honour he was not destined long to enjoy, as, on the 18th December, 1888, the company sustained an irreparable loss in his death. Six months after this event the executors obtained the re-registration of the firm, with the same title, but as an ordinary limited company, with a capital of £750,000.

The *brochure* to which we have alluded gives an account of some of the work done by the firm, but its main object is to explain the means by which results in naval architecture and marine engineering have been effected rather than the results themselves. Full descriptions have been published in the engineering journals and in the Transactions of scientific societies of all the most celebrated ships, but there is only meagre information regarding the appliances and the organisation of a shipbuilding yard, and the publication of a description of such an establishment as that of Fairfield is not only instructive, as showing how from small beginnings there may be immense results, but it is also good because it explains the means which are necessary for producing that most complex organisation, the modern high-class ocean steamship.

THE GERMAN EXHIBITION.

Although this Exhibition has been opened nearly three weeks, the whole of the exhibits are not yet fully in position. Those exhibits which it is within our province to describe are not very numerous, and we can only briefly refer to them in this notice. The Sürther Maschinenfabrik, of Sürth, near Cologne, show a complete plant for generating and liquefying carbonic acid gas. This firm also show some small steam engines. Messrs. Reunert & Douglas, of Berlin, exhibit samples of their iron and steel productions, amongst which we may mention a propeller shaft and forged pieces in crucible, Martin, and Bessemer steel. Messrs. Ad. Altmann & Co., of Berlin, exhibit one of their horizontal petroleum engines. It is claimed for this engine, which is also made of the vertical type, that it is of simple construction, noiseless, and that it occupies very little space. Messrs. Gebr. Reinbold, of Mettman, exhibit their compressed polished steel shafting made of the best Siemens-Martin steel, containing from 0·20 to 0·25 per cent. of carbon. H. Meinecke, of Breslau, exhibits his water meters and hydraulic appliances, and also his portable self-registering water meter, which indicates the amount of waste. Messrs. Werner & Pfleiderer, of London, exhibit some bakers' machinery, amongst which we may mention their universal kneading and mixing machine.

Messrs. Gebr. Stahlknecht, of Stollberg, near Chemnitz, exhibits a new machine for lacing Jacquard cards, which it is claimed can do the work of ten workpeople. The machine, which only requires the attention of one person, can lace from 1,200 to 1,300 cards per hour.

Mr. Rud. Ley, of Arnstadt, exhibits his "Thuringia" boot-pegging machine, which has been in successful use for some time.

Naval architecture is represented by five full models of vessels and one half-model. Most of these are exhibited by the Vulcan Shipbuilding Company, of Stettin—namely, the twin-screw steamer "Furst Bismarck," of 14,000 h.p., belonging to the Hamburg-American Packet Company; the corvette "Irene," built for the German Navy; the ironclad "King Yuen"; the screw steamer "Bremen"; and a half-model of the paddle steamer "Kaiser Wilhelm." The Norddeutscher Lloyd exhibit a beautiful model of their steamers "Spree" and "Havel."

Speaking machines are represented by Berliner's gramophone and Edison's phonograph, which are shown in operation.

Legal Proceedings.

THE WENHAM COMPANY, LIMITED, *v.* THE CHAMPION GAS COMPANY AND MESSRS. TODTENHAUPT & CO.

This was an action brought by the assignees of Frank Wm. Clark's patent, No. 2869 of 1881, to obtain relief by way of an injunction and damages in respect of an infringement of their patent rights. The action was tried by Mr. Justice Vaughan Williams, sitting as an additional judge of the Chancery Division. The counsel appearing were—For the plaintiffs, the Attorney-General, Q.C., Mr. W. T. Aston, Q.C., Mr. J. Fletcher Moulton, Q.C., and Mr. W. N. Lawson, instructed by Messrs. J. H. Johnson, Son, & Ellis; for the defendants, Mr. Morton Daniel and Mr. Jenkins, instructed by Mr. Perks.

The Wenham lamp, in defence of which the action was brought, is well-known as a highly successful form of the regenerative gas lamp. As described in Clark's specification, and by the plaintiff's scientific witnesses, it consists essentially of a combination of the following parts:—A gas-admission tube, which depends from the centre of the

Digitized by Google

lamp cover, and terminates in a circular burner below. An air tube or chamber shorter than the gas-admission tube, but of larger diameter, is disposed concentrically with it about its lower part. This air chamber receives at its upper extremity the air which is intended to support combustion, and brings it down to the level of the burner, just above which it terminates, being closed by a perforated diaphragm serving to distribute the air evenly over the upper surface of the horizontal flame. About this air chamber is arranged concentrically a still larger tube serving as a chimney, which is carried up past the top of the air chamber, and encloses the upper part of the gas-admission tube. The products of combustion in travelling out of the lamp, therefore, heat first the incoming air and next the incoming gas. For the more perfect heating of the incoming air, it is caused to travel up the outer wall of the chimney as high as the top of the inner air chamber already described by the arrangement of a fourth concentric tube open below, where the air from a surrounding chamber is admitted to the annular space so formed, and closed above, save for three radially disposed tubes, which put it into communication at this topmost level across the chimney with the inner air tube. Lastly, the series of concentric tubes so formed is invested by the outer chamber already referred to, which is formed between the cover of the lamp and an horizontal reflector, which is arranged at a convenient height above the flame. In order that there may be a suitable distance between the reflector and the flame the gas-admission tube and the inner air-admission tube are brought down to a lower level within the lamp than the opening of the chimney or the intake of the outer air-admission tube, which last is disposed above the reflector. A further feature of the combination is the admission of a stream of cool air past the outer rim of the reflector and the glass bowl which encloses the flame and forms the lower part of the lamp. This cool air passes into the lamp across the surface of the glass, which it thereby cools and keeps at a moderate temperature, in spite of the radiation of heat from the intensified flame. The combination may, therefore, be summarised as containing the following elements:—(1) A burner supplied with heated air and heated gas, the heating of these components of the flame being effected by a particular arrangement of the chimney and admission tubes respectively; (2) a horizontally burning circular flame, supplied with heated air from a gauze or perforated diaphragm arranged upon its upper or inner surface; (3) a second and independent supply of cold air directed along the surface of the enclosing glass envelope for the purpose of keeping it cool.

The defendant's lamp, though differently constructed, being formed of a casting instead of wrought metal tubes, and having, moreover, certain convolutions introduced for the purpose of increasing the heating surface, must be taken to fall within the above description, since it has by the decision been found to be an infringement. It was, however, contended on the defendant's part that the arrangement of tubes through which the air passes on its way to the burner in the defendant's lamp was materially different from the patented arrangement. The difference chiefly relied upon was that the annular passage up which the air passes along the outside of the chimney forms no part of the defendant's lamp. The annular passage and the encircling chamber above described as being the two outermost members of the combination are represented in the defendant's lamp by one chamber only. For the plaintiff it was contended that this one chamber was strictly analogous to the annular air inlet of the patented lamp—for the defendant that it was, on the contrary, analogous to the circular space between the lamp cover and the reflector which surrounds the entire system of air passages. In argument also, though not in evidence, it was maintained in the defendant's behalf that the ring burner which he uses is perfectly distinct from that shown in the plantiff's drawing, being so much smaller than the base of the air chamber beneath which it burns that the outer edge of the flame does not sensibly extend beyond the base, and the whole flame consequently lies practically in one horizontal plane. In the plantiff's drawing the nipples, from which of course the flame starts, are shown projecting so far over the base of the air-admission tube that the outer edge of the flame would naturally extend over its edge and curl up round it towards the chimney. It was suggested that this alleged difference was of sufficient importance to be relied upon as an answer to the charge of infringement. There were further defences, founded upon want of novelty, and consequently want of patentable matter, in Clark's invention, and upon certain alleged anticipations.

The learned judge, who reserved his judgment and delivered it on a later day, said that if he were to trust to his own impression he should find for the defendants upon the issue of infringement, since it appeared to him that the defendants had adopted an arrangement of parts differing in some material respects from the patented combination. This he said with special reference to the point above mentioned respecting the size and kind of burner used, and the resulting form of the flame. But he observed that the scientific evidence had been directly and entirely contrary to this view, and although raised by the defendant's counsel in summing up the case, that view had not been put to the plaintiff's witnesses. In these circumstances he considered it his duty to disregard his own opinion, and act as bound by the scientific evidence. Proceeding on this footing, he found in favour of the plaintiff, and that the defendant's lamp had infringed the plaintiff's patent. With regard to the objections raised to the patent on the grounds of want of novelty and anticipation, he did not think that they had been made out, and therefore he gave judgment for the plaintiff company on all the issues of the case.

This case is interesting in many ways. Not only does it show a new judge in the capacity of a patent lawyer, but it raises some very important points of principle and practice. Of the great pains which Mr. Justice Vaughan Williams bestowed upon the inquiry and his very judicial frame of mind, it is impossible to speak too highly, and we shall feel in future a large measure of confidence in his ability to deal satisfactorily with the difficult matters with which patent actions teem. Very striking also is the great and, indeed, paramount importance which was in this case attributed to the scientific evidence. It is widely known that the experts called in the plaintiff's behalf—Sir Frederick Bramwell and Dr. John Hopkinson—are men of the highest eminence, whose opinion is entitled to the greatest weight. But they had not actually pronounced an opinion upon the exact point which, in argument, impressed the judge, and his reason for distrusting his own view was in substance this—that that view had not been discussed with the scientific witnesses. We think that this judicial hesitation was eminently judicious, and that if the expert witnesses had been invited to consider the point, they would not have been greatly affected by the facts put to them or have found much difficulty in satisfying the judge that his doubts were unfounded. At any rate the result illustrates in a striking way the importance of taking the utmost care in the conduct of an action that every point on which a party proposes to rely shall receive full attention. It is pleasant to be able to record that in this instance the expert witnesses have received a striking and well-deserved tribute from an able judge.

Upon the great importance of a well-drawn specification, as illustrated by the decision as to costs in this action, it is the less necessary to remark, because the point cannot fail of making its own impression.

Letters to the Editor.

THE ACKROYD-WILLOUGHBY SMOKE PREVENTER AND FUEL ECONOMISER.

To the Editor of "Industries."

Sir,—Your issue of the 15th inst. (which reached me to-day only) contains an account of another endeavour to solve the smoke problem. May I be permitted to say in a few words that the results do not appear conclusive? The system of heating air to support combustion by passing it through iron pipes placed in the boiler flues is not new, having been originally described, if I recollect right, in a patent of Mr. B. H. Thwaite, some three years ago. The objection to this system is that it practically destroys the draught on the fire-grate if the air is introduced over the grate. I quite fail to see—and I think any one with experience will share my difficulty—how there can be a greater aspiratory pressure when a forced air supply is provided over the grate. How is this phenomenon to be explained? The experiments which are described seem to have proved only one thing—that the system is not smokeless.

It is, moreover, clear that by it there will be less combustion, and, consequently, less steam produced per square foot of heating surface, with the result that the efficiency of the boiler is proportionately reduced. The analysis of the fuel is comparatively useless, as the percentage and character of its hydrocarbons are not given.

Yours, &c.,
Manchester, 21st May, 1891. N.

To the Editor of "Industries."

Sir,—I have read Mr. Crosland's report of the trials of this apparatus printed in *Industries* of the 15th inst., and will, with your permission, make some observations on it.

Every one who has had occasion to scrutinise the evidence furnished by the trials of new inventions, and adduced by inventors to support their claims, must have remarked how frequently such evidence is misinterpreted, and how often results attributed to the application of a patent apparatus have in reality been produced by causes altogether independent of its action. The present is a case in point. In the trials under discussion, black smoke was entirely prevented and the evaporative efficiency of the boiler was increased by 20·5 per cent. when the "smoke preventer and fuel economiser" was in use, and the report attributes both advantages to the action of the apparatus. In reality no such relation of cause and effect is proved to have existed. On the contrary, the evidence tends to show that the great improvement on the second day was mainly, if not altogether, due to a change in the conditions under which the trials were made, and that the same improvement would have followed the same change of conditions if the patent apparatus had not been applied.

Let us consider the question of smoke prevention first. It is easy to see why dense black smoke was made at the first trial. Furnaces with little more than half the usual allowance of air spaces between the bars, loaded, at long intervals, with 200lb., or from eighteen to twenty shovelfuls of coal, and closed by doors apparently air-tight, could not do otherwise than smoke abundantly. Indeed, it would seem that those entrusted with the management of the trial had taken all needful precautions to make smoke in order to prove that there was really something for the "smoke preventer" to prevent. If so, it would surely have been consistent to have taken the same precautions on the second day, instead of reducing the weight of the charges and largely increasing the supply of air. Owing to this inconsistency the trials are altogether inconclusive. They neither proved the possibility of burning 840lb. of coal per hour without smoke with the apparatus, nor the impossibility of so burning 659lb. without it. Experience, however, goes to show that, with a chimney 110ft. high and 5·64 square feet area, it is quite possible to burn 16½lb. of coal, and even 21lb. of coal, per square foot of grate per hour in a reasonably constructed furnace of the ordinary kind, without making either carbonic oxide or dense smoke, especially when the same care is exercised in admitting air through the furnace doors as was used in manipulating the steam jet on the second trial. And thus we are led to the conclusion that the "preventer," if, indeed, it prevented anything at all, prevented only that which, but for the special arrangements made, would not have existed for it to prevent.

And if the claim of 17 per cent. net saving be examined, it will be found equally affected by the change in the conditions under which the trials were made. No one will pretend that a boiler having 1 square foot of heating surface for each lb. of coal burnt per hour will work as economically as one having 2 square feet. The difference in the ratio of heating surface to coal burnt on the trials was not so great as this, but still it was sufficient to affect the rate of evaporation per lb. of coal very sensibly. The heating surface was 941 square feet, and the hourly consumption of coal 840lb. on the first day, and 659lb. on the second. There was, therefore, 1·12 square feet per lb. of coal in the one case, and 1·43 square feet in the other, an increase which at once accounts for about 10 per cent. out of the 17 per cent. net saving claimed for the "preventer."

The remainder of the claim is quite as easily disposed of. Carbonic oxide was made on the first day in sufficient quantity to cause a loss of 818 thermal units per lb. of coal. None was made on the second day, and, with a supply of 20lb. of air per lb. of coal, none would have been made if the "preventer" had not been in action. The heat thus lost was sufficient to have increased the evaporation of 6·64lb. by 0·98lb., or by 14¾ per cent. The evidence, therefore, shows that, if the boiler had been as lightly fired on the first day as on the second, and if the furnaces had not been specially constructed and worked to make carbonic acid gas, the evaporation on the first day would have been about 24 per cent. greater than it actually was, and in excess of that obtained on the second day with the aid of the patent "fuel economiser." Therefore, the conclusion seems to be that the great improvement made was due, not to the action of the apparatus, but to the removal of two adverse conditions which need never have been introduced.

By what process of reasoning can any one persuade himself of the possibility of saving 20 per cent. of coal by putting heat into one part of a boiler which has been taken from another part, for this is really the process by which the evaporation is said to have been increased one-fifth. It is simply robbing Peter to pay Paul. If the heat had been taken from the waste gases in the chimney, some of the saving might have been put to the credit of the apparatus, but I do not think that even then we could admit quite all claimed in the report, seeing that to obtain it practically the whole of the heat passing up the chimney would have had to be absorbed.

Had the conditions of trials been properly arranged, and had the results shown that with the aid of the apparatus it was possible to burn coal smokelessly with less air than without that aid, the "smoke preventer and fuel economiser" might have justified its title. As it is, one can only regret that in making so complete a trial the essential conditions and points at issue should have been so completely overlooked and serious countenance given to a claim which is, on the face of it, absurd.

The report, too, would have been more satisfactory if the usual balance sheet had been given, together with some explanation of the great difference in the quantities of heat unaccounted for on the two days.

Yours, &c.,
Ancient Mariner.

26th May, 1891.

RATING OF MACHINERY.

To the Editor of "Industries."

Sir,—My attention has been called to a paragraph which has been going the round of the Press with reference to the compromise of the Chard Appeals. As this paragraph is evidently inspired, and conveys an entirely erroneous impression, may I ask a portion of your space to state the real facts?

The aggregate amount of the valuations of the various appellants made by the Union valuers was £6,579. This amount has now been reduced, in consequence of the appeal, to £4,899, being a net reduction in rateable value of £1,680. By these figures it will be seen that an attempt has been made to rate these appellants at a sum equal to about 34 per cent. in excess of the amount now admitted to be reasonable. Further justification is hardly needed for the attempt of machinery users to secure the amendment of a law which allows them to be harassed in this manner. The fact that (after spending thousands of pounds of the ratepayers' money in a litigation lasting nearly three years, and embarked upon with the object of maintaining the correctness of this valuation) the Committee have agreed to such terms, not only affords a strong comment on the wisdom of their proceedings, but clearly shows what good ground the appellants had for the resistance they have offered, while the success that has attended their action shows the necessity and value of determined opposition to attacks of this kind.

This Society has been able to afford the appellants valuable assistance, and machinery users similarly affected should at once communicate with me. It is not the manufacturers who have admitted anything by this compromise, but rather their opponents,

Digitized by Google

and all attempts to rate machinery wherever made will be contested to the uttermost—these cases were only compromised because the offer made left nothing worth fighting for.

The supporters of what is called "the rating of machinery" have made haste to claim the result of the Chard cases as a victory. They have had more than one such victory recently, including the second reading of the Bill for amending the law as to the rating of factories, when their success was so great that they were unable to raise a debate, and did not divide the House. Their only hope of defeating this Bill now lies in obstructive tactics.

To add to the absurdity of the position into which our opponents are driven, while they talk in the Press and elsewhere about machinery being rateable, there is not one of those gentlemen who can be found bold enough to contend in a court of law that machinery is rateable *per se*, or to give any intelligible explanation of the principles on which they value machinery for rating purposes. In the Tyne boiler case, of which so much is heard, Lord Esher said, referring to the machinery there in dispute, "these are chattels, they are not rateable as chattels which nobody disputes, they are not rateable at all as themselves." No doubt, by miserable quibbling, the appellants in that particular case were defeated, but in future cases this Society will take care that the main issue is not evaded.

The statement that the appellants pay all the costs of the appeals is also misleading. Perhaps some ratepayer in the Union will take the trouble of investigating the amounts which have been paid by the Committee to the Attorney-General and the other counsel, to their late and present solicitors, their surveyors and others, including also the taxed costs they had to pay the appellants at Quarter Sessions, and I think it will be found that the net balance paid by the appellants to the respondents does not exceed 10 per cent. of their total costs.

Yours, &c.,
G. Humphreys Davies,
Secretary.

THE STRESSES IN BOILER SHELLS.

To the Editor of "Industries."

Sir,—I had hoped that the suggestive paper by Mr. Spence which appeared in your journal on the 18th of March, and the able mathematical investigation by Mr. Slade, on "The Stresses in Boiler Shells," would have attracted the attention of some of your readers, and led to a correspondence on a very important subject, for it cannot be considered at all satisfactory that such a question should be left in the position it has been by the two writers I have mentioned. Mr. Spence is an experienced practical engineer, while Mr. Slade has also had considerable practice, and in addition is an accomplished mathematician, and, therefore, the opinions of both are deserving of careful consideration. At this time of day we cannot allow that theory is necessarily opposed to practice; if it is, one or other, or possibly both, must be wrong, and we should not be content until we have placed matters on a proper basis.

I must say frankly that the manner in which the stresses in boiler shells has hitherto been treated by writers on the subject at least justified Mr. Spence in making experiments to test the correctness of their conclusions. In a paper which he read before the North-East Coast Institution of Engineers last year, he argued that it was unnecessary to make a boiler as strong as if it were an endless ring, and that the resistance due to the connection between shell and ends should be added to the circumferential resistance of the shell, in order to get the true strength of the structure. Of course, if this were true, the strength of boilers, especially of the marine type, would not be, as hitherto assumed, independent of their length, but would depend as much on their length as on their diameter. The ordinary theory is that

$$2ftl = pdl,$$

or,

$$f = \frac{pd}{2t},$$

where f is the intensity of the tensile stress resisting rupture along the longitudinal seams, d is the diameter, l the length, and t the thickness, while p is the uniform internal pressure. There are several assumptions in this theory, and of these the most important is that we are dealing with a tube of endless length, or at least that the influence of the ends on the strength is so small that it may be neglected, and, further, that the thickness is small in comparison to the diameter, which, of course, it always is in ordinary cases. When it is not other expressions are used. Writers on the theory of an engineering subject are too apt to make assumptions, and then to add the still further assumption that their conclusions are infallible laws of nature. A great deal of what has been called the theory of the steam engine has been of this nature; in fact, it is to be doubted whether the so-called theory of the steam engine has not been the means of retarding progress. If what was taught of the action of steam in cylinders had been depended on, the greatest improvement which has taken place in steam engines during the past quarter of a century would not have been carried out, for we were taught that from a theoretical point of view it did not matter whether the expansion of steam was carried out in one or more cylinders. Then, again, the conditions of Carnot's theoretical engine have been applied to actual engines working under very different conditions, and most ridiculous conclusions have been drawn.

I simply mention these facts for the purpose of showing that we ought to approach the subject raised by Mr. Spence with unprejudiced minds, and probably we may be convinced, like him, that the strength of cylindrical boilers is still an unsolved problem, and find that, as he indicates, the true solution of the problem will apply equally to boiler shells subject to internal and to flues subject to external pressure. It does not follow that, because the theory hitherto adopted for the strength of boilers is incomplete, that therefore the conclusions arrived at are wrong, for the omitted elements may balance each other.

I have read Mr. Slade's paper with care, and it seems to show that these conclusions are at least approximately correct, and that it would be highly dangerous for any one to accept Mr. Spence's results, and make boiler shells half the present thickness in the hope of getting the load carried by the ends. Him shortly before his death expressed the opinion that in the present state of our knowledge it was impossible to work out a complete theory of the steam engine. May it not also be true that a marine boiler is so complex a structure, made up of shell, stays, flues, tubes, ends, &c., that all we can expect from theory or calculation is a first approximation to the required dimensions, and that we must depend on experiment for an answer to such questions as that raised by Mr. Spence. He has gone in the right direction, but before the question is decided the experiments must be on actual boilers, and not on models. This seems a work which might be undertaken by the Board of Trade.

Yours, &c.,
M.I.N.A.

Glasgow, 23rd May, 1891.

A DEPARTMENT OF LABOUR.

To the Editor of "Industries."

Sir,—In a letter which I sent to you on the subject of "The Labour Commission," and which you were good enough to publish in your issue of the 24th ult., I suggested that possibly the most tangible result of the Commission would be a department of labour or industry which would look after the interests of all sections of the industrial classes, workers and employers alike, and would also collect information on all points of interest and receive evidence from all parties who were likely to throw any light on any part of the labour problem. Its chief duties would be to collect trade statistics and information regarding the hours of labour in different industries and occupations, the scope and results of the Factory Acts, and the employment of women and children, while it might also take charge of the arrangements connected with arbitration, and the settlement of trade disputes generally, and all proposals connected with these questions.

I am pleased to learn that such proposals are beginning to take definite shape, and that Lord Dunraven is to bring the matter of the organisation of a department of State for dealing with labour questions generally before Parliament at an early date. His Lordship, as is well known, has taken a very active interest in all matters referring to the welfare of the working classes, and, like all who have done so, he finds that the Labour Bureau of the Board of Trade is inadequate to the great importance of the subject. As has been pointed out by you, this is not the fault of those in charge of it, but arises from the fact that the Department is starved. I do not know what steps his Lordship intends to take in this matter, but as the arrangements ought to be gone about with great deliberation and full understanding of all the difficulties of the work, I would suggest that it be made a suggestion to the Labour Commission to inquire and report into the desirability of having a Labour Department. Your article on "Trusts," in your issue of last week, shows the advisability of another suggestion which I made—that is, of investigating the scope of Government interference in special departments of industry when these tend to become monopolies. I pointed out that in those class of syndicates, trusts and "rings," it might soon become necessary to have a policeman on the Board of Directors to look after the public interests.

Yours, &c.,
Economist.

Leeds, 26th May, 1891.

SHIPBUILDING NOTES.

On the 7th inst. Messrs. Sir Raylton Dixon & Co. launched from their No. 2 Dockyard, Middlesbrough, an iron steam trawler, the "Albion," built to the order of the Great Grimsby Albion Steam Fishing Company, Limited, Grimsby. The leading dimensions are:—Length, between perpendiculars, 96ft.; breadth, 20ft. 5in.; depth, moulded, 11ft. 8in. The engines will be supplied by Messrs. Westgarth, English, & Co., having cylinders 11in., 17in., and 28in., by 20in. stroke.

On the 7th inst. Messrs. Sir Raylton Dixon & Co. launched from their No. 2 Dockyard, Middlesbrough, an iron steam trawler, the "Cynthia," which has been built for Messrs. Mitchell & Allen, of Grimsby. The vessel is of the following dimensions:—Length, between perpendiculars, 96ft.; breadth, 20ft. 5in.; depth, moulded, 11ft. 8in. The engines will be supplied by Messrs. Westgarth, English, & Co., on the triple-expansion principle, having cylinders 11in., 17in., and 28in., by 20in. stroke.

On the 9th inst. Messrs. Wm. Simons & Co., Renfrew launched from their works a self-propelling hopper dredger, constructed by them for the Indian Government. The vessel is specially designed for dredging in shoal water. When propelling, the bucket ladder and upper gearing are lowered to the deck level, thus greatly improving the seagoing qualities of the vessel and increasing its stability, and, when dredging, these again are traversed on a diagonal framing to the upper position, enabling the buckets to be projected in advance of the hull. The vessel has a capacity in its hopper to hold 400 tons of dredgings. This is the fifth dredging steamer constructed by this firm for Indian ports.

On the 14th inst. the new steel paddle steamer, "Duchess of Devonshire," recently built by Messrs. Richard & Henry Green, of Blackwall, London, had a successful trial trip. The principal dimensions of the vessel are:—Length, over all, 178ft. 6in.; breadth, moulded, 20ft.; depth, moulded, 8ft. 3in. Her engines, of the compound diagonal type, have been constructed by Messrs. John Penn & Sons, of Greenwich, and gave satisfactory results. The cylinders are 45in. and 22½in., with a stroke of 3ft., indicating 400 h.p., with a speed of 12½ knots. The vessel is built to the order of the Devon Steamship Company, of Exmouth.

A new twin-screw steamer, the Tynwald," was recently launched by the Fairfield Shipbuilding and Engineering Company for the Isle of Man Steam Packet Company. The vessel will ply between the Clyde and the Isle of Man during the summer, and from Liverpool to Douglas during the winter. The engines will be of the triple-expansion inverted type, the cylinders being 22in., 36in., and 57in. diameter respectively. Two double-ended boilers are fitted tandem, and are worked at a pressure of 160lb. to the square inch.

On the 16th inst. the new twin-screw steamer "Kwarra," built and engined by the Naval Construction and Armaments Company, Ld., Barrow, to the order of Messrs. Elder, Dempster, & Co. (who have since sold her to the African Steamship Company, of Liverpool), left Barrow for her trial trip. Everything passed off successfully, and the working of the machinery proved very satisfactory. She was docked in Liverpool the same evening. The "Kwarra" sailed from Liverpool for Lagos on the 23rd inst. on her maiden trip.

On the 22nd inst. Messrs. Wm. Simons & Co. launched complete from their yard at Renfrew the third of three steam hopper barges for the Corporation of Preston. The dimensions of the vessel are as follow:—Length, 130ft.; breadth, 24ft.; depth, 9½ft., and it has a hopper capacity to contain 300 tons of dredgings. The engines will indicate 250 h.p. The two former vessels, which have been launched within the last two months, are now at work at Preston.

On the 23rd inst. Messrs. Murray Bros., Dumbarton, launched the "Clutha No. 10," a twin-screw steamer for the up and down river passenger service of the Clyde Trustees. The dimensions of the vessel are 90ft. by 17ft. by 8ft. 3in. The compound engines are by Messrs. Matthew Paul & Co., Dumbarton.

On the 23rd inst. the Grangemouth Dockyard Company launched the "Meteoro," a twin-screw steamer for Rio Janeiro. The dimensions of the "Meteoro" are 220ft. by 35ft. by 19½ft. The engines have been made by Messrs. Hutson & Corbet, Glasgow.

On the 23rd inst. the Grangemouth Dockyard Company also launched a steel barque of 1,200 tons, built at their yard at Alloa for Mr. A. O. Ludvig, Kragero, Norway.

On the 26th inst. Messrs. Barclay, Curle, & Co., Ld., Whiteinch, launched the "Crondale," a steel sailing vessel of 1,900 tons. The vessel has been built to the order of Messrs. Donaldson, Rose, & Co., Aberdeen.

On the 23rd inst. Messrs. Ropner & Son launched the steel screw steamer "Venus," of the following dimensions:—Length, over all, 324ft.; breadth, 40ft. 6in.; depth, moulded, 23ft. 7in. This steamer has been built under special survey to class 100 A1 at Lloyd's to the order of Messrs. Thos. Robinson, Sons, & Co., of West Hartlepool. The vessel is provided with cellular bottom for water ballast, and is built on the web frame principle. The engines are by Messrs. Blair & Co., Ld., of 1,200 h.p., with two steel boilers working at 160lb.

On the 26th inst. Messrs. Richardson, Duck, & Co. launched from their building yard at South Stockton a steel screw steamer, "Sidney Thomas," of the following dimensions, viz.:—Length, over all, 307ft. 4in.; breadth, extreme, 40ft.; depth, moulded, 21ft. 8½in. This vessel, which has been built for Messrs. Andrew Low, Son, & Carter, London, is classed 100 A1 at Lloyd's. She has a cellular bottom fore and aft for water ballast. The engines, by Messrs. Blair & Co., Ld., of Stockton, are of the triple-expansion type, with cylinders 20in., 36in., and 59in., by 39in. stroke.

On the 26th inst. Messrs. Edward Withy & Co. launched from their yard at Hartlepool the large steel screw steamer "Salopia," built to the order of Mr. George Steel, West Hartlepool, for Messrs. Steel, Young, & Co., of London. This is the one hundred and eighty-second vessel constructed by this firm, and the thirty-fourth built in the Hartlepools for the same owners, thirty of these having been built by Messrs. Edward Withy & Co. The vessel is a fine type of a modern cargo boat, measuring over 300ft. in length, and built throughout of Siemens-Martin steel, and is built to the highest class at Lloyd's. A cellular bottom is fitted all fore and aft for water ballast. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. The vessel will be fitted with triple-expansion engines by Messrs. Richardson & Sons, Hartlepool.

Reviews.

Special Inquiry into the Zone Railway System. Glasgow: James Hedderwick & Co. 1890.

During last year (see *Industrie*, Vol. IX., page 382) we gave a short account of the zone system of railways as described by a special Commissioner of the Glasgow *Evening Citizen*, with the hope that the attention both of the public and of the railway authorities might be directed to the zone system of tariffs, so that they might consider whether it, or some modification of it, is at all suitable to the conditions of this country. We are glad to observe that the letters to which we referred have been published in pamphlet form, and thus rendered more accessible to the general public The pamphlet lucidly explains the arrangements which have been made in Austria-Hungary for the promotion of cheap passenger traffic on remunerative terms, and it also makes suggestions which might be usefully applied in this country, and points out some lessons which might be derived from certain arrangements on Prussian railways which in four years raised the number of passengers carried on State

Digitized by Google

railways by about seven millions. It also points out that in some respects the zone system has been adopted in this country, and the writer quotes the arrangements of the Glasgow and South-Western Railway, and urges the directors to proceed a little further in the same direction. We commend the pamphlet to the careful attention of our readers.

Fuels, Their Analysis and Valuation. By H. J. Phillips. London: Crosby Lockwood & Son. 1891.

The author believes that the great progress made in recent years in the adaptation of various kinds of fuel to special purposes is sufficient to warrant the issue of his work, which deals with the methods of analysis and valuation of solid, liquid, and gaseous fuels, and gives a collection of tables showing the composition and consumption of various fuels in use in locomotives, &c. The methods of analysis described comprise the estimation as ash, carbon, coke, sulphur, volatile matter, &c., the flash point in liquid fuels, and elementary gas analysis as applied to gaseous fuels. A short description of Thomson's calorimeter and its use for estimating the calorific value of a sample of fuel is also given. There are a few printers' errors in the book—*e.g.*, that on p. 10, where the tension of aqueous vapour at 15° C. is stated to be equivalent to "12,677 mm. of mercury," which should be corrected in a future edition. We consider it a handy little work, and likely to prove useful to engineers and all who consume fuel for manufacturing or industrial purposes.

An Introduction to the Study of Metallurgy. By W. C. Roberts-Austen, C.B., F.R.S. London: C. Griffin & Co. 1891.

In view of the fact that the value of metals obtained by smelting ores in the United Kingdom amounts to nearly fourteen and a half million pounds sterling annually, it is remarkable that the English literature of metallurgy is so scanty. Besides the classic, but now antiquated, treatises of Percy, we can only recall the useful manual of Phillips and Bauerman. We are glad, therefore, to welcome Professor Roberts-Austen's addition to the limited list. Metallurgy has undergone a remarkable change within the last few years. With the practical disappearance of the older methods of manufacturing steel in favour of the more modern ones, the problems that formerly arrested the attention of metallurgists have now given place to others of greater technical importance. The older questions were based chiefly on empirical reasons, whilst the modern ones have a more scientific basis. By no means the least amongst these is the question of molecular constitution. Chemical analysis is no longer the sole factor. Physical questions, dealing, for example, with the casting, forging, hardening, annealing, and heating of metals, are now receiving much attention, and are leading to the introduction of changes in the methods of manipulation. Such studies, formerly of mere theoretical interest, have acquired practical importance. These facts have evidently been borne in mind by Professor Roberts-Austen in the preparation of his admirable treatise, and in his first four chapters on the relation of metallurgy to chemistry, on the physical properties of metals, on alloys, and on the thermal treatment of metals, he clearly shows what kind of aid the metallurgical art may be expected to receive in future from the sciences.

The author's long experience as Professor of Metallurgy at the School of Mines, or, as it is now called, the Royal College of Science, and as examiner in metallurgy to the Science and Art Department and to the City and Guilds of London Institute, have shown him the defects of the metallurgical text-books in vogue, in which the important metals are dealt with separately and in detail. He has, therefore, adopted a more rational method, by which the subject is treated as a whole. He gives no minute description of processes, but selects for description typical appliances, indicating their use in connection with groups of metals. By thus systematising the study of metallurgy, which has hitherto been a heterogeneous mass of disconnected facts, his book marks an epoch in the history of the teaching of metallurgy in this country. This section of the subject is treated in five chapters, dealing respectively with fuel, with the materials and products of metallurgical processes, with furnaces, with the means of supplying air to them, and with typical metallurgical processes. The last chapter is of interest to the political economist as well as to the metallurgist. It deals with the principles by which the relations of capital and labour are guided, and with the economic conditions under which metallurgical works are carried on.

In the treatment of the subject every care appears to have been taken to secure accuracy. As an illustration of this we notice that some figures relating to furnace charges borrowed from Professor Balling have been recalculated, and some errors that occur in the original German work have been corrected. The same care is noticeable in the numerous reference to authorities, these references forming a bibliography of metallurgy that will render the volume valuable, not only to the student, but also to the metallurgical expert. The book is furnished with eighty-three well-drawn illustrations, and, we are pleased to note, with a good index—unfortunately rare in technical works. As a condensed account of the theory and practice of modern metallurgy Professor Roberts-Austen's work cannot fail to be an invaluable auxiliary to the more exhaustive works on the subject, and students are to be congratulated that the author has been induced to place the results of his ripe experience in an accessible form.

The History and Development of Steam Locomotion on Common Roads. By William Fletcher. London: E. & F. N. Spon. Ipswich: Printed and published by S. H. Cowell. 1891.

It is somewhat curious to note that, among all the books which have been written on different departments of mechanical engineering, the history of the application of steam locomotion on common roads has received very little attention. Mr. Fletcher gives a list of the works from which he has extracted information, but these are for the most part general treatises, which only take up the subject of locomotion on common roads in an incidental manner, and Mr. Fletcher's book may be considered the most complete which as yet has appeared on the subject. Some of the earlier parts of it appeared in various technical journals, including our own, and the author acknowledges his indebtness to these journals for many of the illustrations. The historical method of studying a subject is one of the most instructive, and in no department could it be made more useful than in that of engineering. We would not, of course, advise a search into all the antiquated forms of different kinds of machines, but simply a careful study of typical designs which mark steps in their development, and which record the work of the best and most successful men who have worked in the same direction. By this method we can examine their difficulties, appreciate their obstacles, measure their mistakes and errors of judgment, and mark the steps which led to success.

The book is divided into seven sections:—(1) Introduction; (2) the period of speculation; (3) the period of experiment; (4) the period of successful application; (5) the modern period; (6) practical notes on the design and construction of road locomotives; and (7) traction engine law. The first five of these sections are chiefly historical, and contain much useful as well as curious information. Not only had difficulties of construction to be overcome, but also difficulties occasioned by public opinion being prejudiced against the engines. Mr. Fletcher says that the steam carriages of the early days were hooted and hissed at by road authorities, coach-drivers, publicans, and the multifarious men who delighted in horses, which perhaps was not to be wondered at, seeing that the interests of these men were at stake; but engineers and others, who ought to have known better, joined in the crusade against steam on common roads, from the celebrated James Watt, who actually put a covenant in the lease of his house, Heathfield Hall, that "no steam carriage should, on any pretence, be allowed to approach the house."

Mr. Fletcher gives an interesting account of how these difficulties were overcome, and enters into details of modern designs. This part of the book is, in fact, a treatise on traction engines, for his illustrations are clear and distinct, and his details of dimensions and proportions sufficient to guide design. He has, moreover, a special chapter containing notes on the design and construction of road locomotives, which will be found most useful. He concludes by directing the reader's attention to several unreasonable and almost prohibitive clauses in the Road Locomotive Acts of 1861, 1865, and 1878, now in force.

Mr. Fletcher's book has been printed and published in his own locality, and wants some of the finish which characterises books published in the metropolis, and he explains that it has been written in the intervals of business, and that doubtless some of the faults of the work are occasioned by this circumstance. However, books by practical engineers are always welcome, and we can pardon a few faults in literary arrangement. Mr. Fletcher's book forms altogether a valuable addition to the engineer's library.

Strength and Properties of Materials. By W. G. Kirkaldy. London: Sampson Low, Marston, Searle, & Rivington, Limited. 1891.

This large and handsome volume, containing 216 pages of text, 104 pages of tabulated data, comprising the results of 12,000 selected experiments, illustrated by 47 pages of lithograph-plates, and published at four guineas, may, in a sense, be considered the development of a paper, which the father of the author, Mr. David Kirkaldy, read before the Institution of Engineers in Scotland in 1859, giving the results of some experiments which he had carried out for Messrs. Robert Napier & Sons. These experiments seem to have given the bent to the whole of Mr. Kirkaldy's after career. In 1862 he published a treatise on the "Results of an Experimental Inquiry into the Comparative Tensile Strength and other Properties of various kinds of Wrought Iron and Steel," which contained a vast amount of useful information, and was much consulted by engineers, until the change in the character of the materials made the data antiquated. Shortly after the publication of that work, Mr. Kirkaldy went to London, and established the testing business, in connection with which his name is so well known, and the volume we are noticing comprises a selection of the results obtained during the past quarter of a century, showing the strength and other properties of materials used in construction.

The leading objects of the work are stated to be:—(1) To show the present state and extent of the testing works; (2) to explain the system of carrying out experiments of various classes; (3) to place in available form valuable information and data for professional men, in conjunction with which are explanations of details and comments to extend the practical benefits to be derived from the results set forth; (4) to record what David Kirkaldy has experienced in his professional career, and to establish his labours by giving the reader the means of judging his actions, with the hope that, by making known some of the treatment that he has been subjected to, the support of those who uphold fair-dealing may be stimulated. The first part is not so specific as regards details as we would have liked to have seen it, for while it gives a very good idea of the buildings and of their contents in a general way, it omits to give what would be of the greatest interest to engineers—namely, a description of the splendid testing machine which Mr. Kirkaldy designed and of which he superintended the construction. For this he deserves the very highest credit, for, although many machines have since been made, Mr. Kirkaldy's is not only one of the most powerful in existence, but also one of the best. When we compare it with the simple lever with which he made his experiments at Napier's, we realise the great step which Mr. Kirkaldy took. The system of testing which is carried out for commercial and scientific purposes is fully explained in the second section of the book. The third section is the one which will be of the greatest use to engineers, and which will, therefore, be pursued by them with a great amount of interest, as it contains a number of reports of tests with commentaries on them. The lithographed plates have been very carefully drawn, and are most instructive in many respects, and the conclusions deduced will for the most part be agreed to by engineers. There are, however, some points to which exception will be taken, but into these our space will not allow us to enter. The record of the professional career of such men as David Kirkaldy is always instructive, but we think that some of the personal details and reflections might have been omitted. No doubt, like other men, he has been often misunderstood, and possibly in some cases suffered injustice, but a volume like the present was scarcely the place in which to record grievances. Most of them, we are afraid, had their origin in his uncompromising honesty, and his somewhat rugged Scotch character. We are glad, however, that his work has had such a worthy record, and we hope it will find a place in all standard libraries.

THE TOMLINSON SUB-STATION REGULATOR.

As electrical engineers become more fully alive to the waste of power in transformers kept in circuit all day, the sub-station method of distributing alternating currents is coming more to the front. Mr. J. E. H. Gordon has recently exhibited a most ingenious sub-station regulator. It is the invention of Mr. Thomas Tomlinson, and is designed for cases where there are a number of transformers at each sub-station.

The Tomlinson apparatus, which we illustrate in Fig. 1 on page 522, is provided with four sets of switches, and the transformers are arranged in five groups. One group is permanently connected to the mains, and one more is connected through each set of switches respectively. Suppose that one transformer is permanently connected to the mains, then one would be connected to the first switch, two to the second, four to the third, and eight to the fourth, so that the putting in of each switch doubles the number of transformers in circuit. With a current of 1,500 lamps on a single switch no spark whatever is visible. The switches are thrown over by a sliding carriage in the form of a double wedge, which

Constructed by Messrs. J. E. H. Gordon & Co., Limited, Electrical Engineers, London.

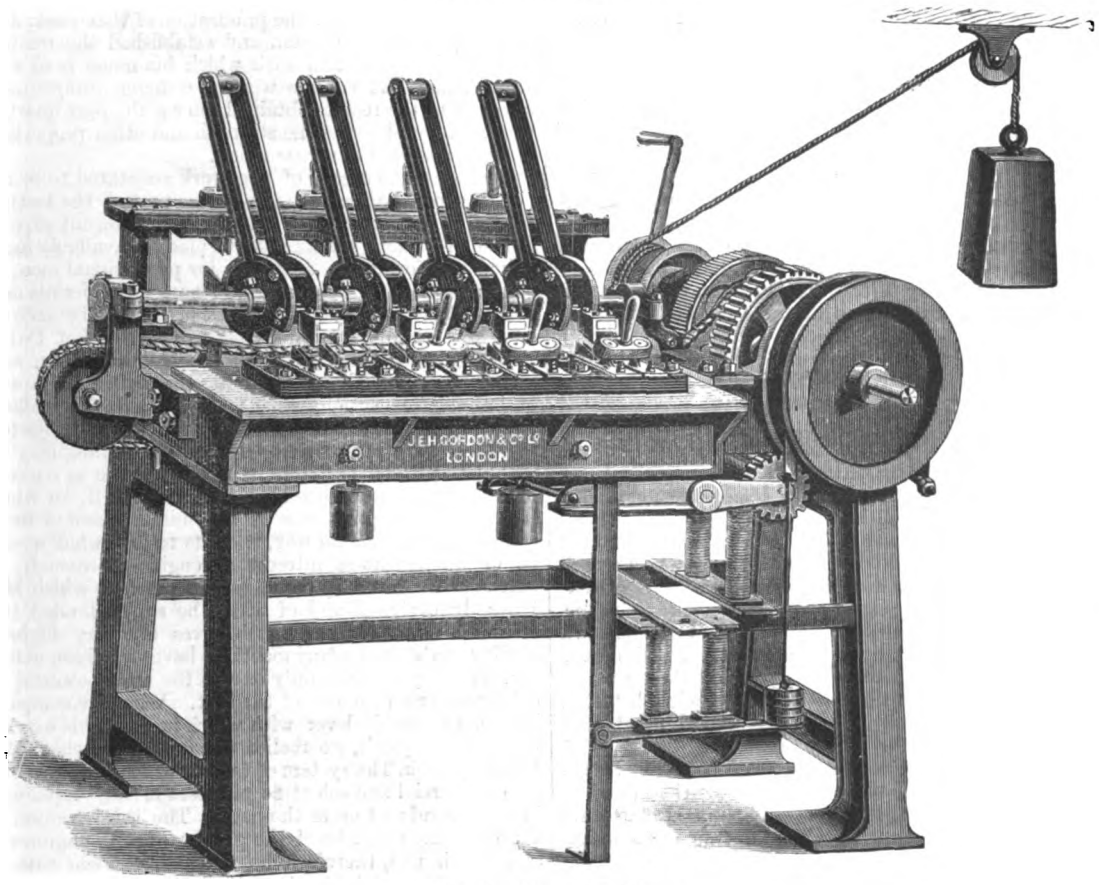

Fig. 1.—General View.

runs backwards and forwards along the bed-plate of the machine, and, as it passes each switch, throws over a tumbling lever, which strikes the switch suddenly in or out of contact.

This carriage is moved by an endless chain actuated by two weights, which are released respectively by two electromagnets. The large weight which takes the transformers out of circuit has to be wound up once a week, and, as it takes out the transformers, it at the same time winds up a smaller weight ready to put them in again. If any failure whatever of the large driving weight occurs, or if the attendant forgets to wind it up, the small weight is always ready to put the whole of the transformers into circuit, and must do this before the apparatus becomes inoperative.

The apparatus has been tried practically through the courtesy of the Brush Company, the Electric Construction Company having also lent transformers for the experiment.

The plant was first run for twenty-four hours with the transformers connected in the ordinary manner, and then for twenty-four hours with them connected through the Tomlinson regulator, and coal and water were measured throughout the experiments. The actual saving in coal was carefully determined, and the use of the regulator showed a saving amounting to an extra dividend of nearly two per cent.

ON SOME POINTS CONNECTED WITH MAINS FOR ELECTRIC LIGHTING.*

My object is to extol the "sweet simplicity" of the two-wire system, the practical security of concentric mains, and the unquestionable economy of the high-pressure principle. I do not intend to discuss overhead wires. I consider them, for high-pressure electric light circuits, an abomination, especially as it is easy to show that ultimate economy is in favour of the underground system. It is only the first capital expenditure that favours overground mains; safety, freedom from accident, ease of repair, and renewals are all the other way. The only limit to the use of extra high pressures, or to the voltage employed, is the efficiency, economy, and durability of insulating materials.

There is one objection to most mineral hydrocarbons—viz., that they require to be encased in lead; but oil has this advantage—that it can be used in iron pipes as in the method adopted by Brooks. Lead covering is expensive, and it adds seriously to the weight of the cable, so as to render more difficult its handling and drawing in and out. On the other hand, lead adds materially to the life of the cable. I have in my possession samples of lead-covered wire which were buried in 1844, and in which the conductor and insulating medium are now as perfect as when made. Lead, however, in some localities, especially in decaying vegetable matter, is itself attacked. When, however, properly protected, it ought to last for centuries. The lead used by the Romans to distribute water in Pompeii is still visible. Lead-covered cables are very largely used in America, Germany, and France, and their employment is rapidly extending in England.

The points that determine the distribution of low pressure are fall of potential, and number of feeding points and distributing stations. We need not consider the heating of conductors. If we take care of the potentials, the waste will take care of itself.

One ton of copper of 1 square inch sectional area covers a length of 192·3 yards, and its resistance is ·0046 ω. Hence, a length of 220 yards weighs 1·13 tons, and its resistance is ·00527 ω. A pair of such mains will weigh 2·26 tons, and their resistance will be ·01054 ω. 1,000 amperes means, therefore, a loss of 10½ per cent. (and 1 kilowatt is wasted in every 43·4 yards), 500 amperes means a loss of 5¼ per cent., and 237 amperes means a loss of 2½ per cent., in such a circuit when the full load is supposed to be concentrated at the end. If we take a fall of potential of 2½ per cent. in each main, which is the recognised maximum waste at full load allowed to comply well with Thomson's law, it means 474 amperes delivered at 100 volts, or 1,600 8 c.p. lamps served. In fact, we may say that two mains of 1 square inch copper will serve 1,600 8 c.p. lamps at 220 yards distance; and this appears to be the commercial limit of the two-wire low-pressure distribution. Of course, if we are content to admit a greater waste, this limit of distance can be extended, and the number of lamps to be served can be increased in the same ratio. The exact waste to be allowed is an economical question governed a good deal by the conditions of the problem, financial as well as engineering. Now, if we add another 100 volts at the points of supply, we can deliver the same energy for the same number of lamps with the same loss at 880 yards; and for every additional 100 volts delivered, we can extend the distance to which the supply can be driven under similar conditions, as the square of the unit distance, 220 yards, for to maintain the same energy the current is *diminished* in the same ratio. Thus 2,050 volts will drive the energy required for 1,600 8 c.p. lamps fifty miles if we use mains of 1 square inch sectional area, and are satisfied to waste only 5 per cent. of the driving energy. Professor John Hopkinson, F.R.S., showed how,* by the use of an intermediate third wire and two dynamos, we could use 200 volts with our present lamps, and therefore we could practically diminish for the same distance the weight of copper used by one-half, or we could make the same weight of copper serve double the distance. The third wire, however, diminishes the effective economy of the plan. Its practical commercial limit appears to be about half a mile; and its disadvantages to be, more dynamos to work, and considerable complication to adjust and regulate the equilibrium of lamps on the circuit.

There is no practical limit to the high-pressure system: 10,000 volts will drive energy from Deptford to London on two mains of ¼ square inch section to serve 50,000 lamps; and 27,000 volts will drive 300 h.p. 112 miles, from Lauffen to Frankfort, on a conductor of ·06 square inch sectional area—*i.e.*, a No. 2 copper wire. But we have to take into consideration the difficulties of the distribution. On the two-wire system this means one central station for each effective area having a mean radius of 220 yards. On the three-wire system this area can be extended to a mean radius of one-half mile; the five-wire system extends the mean radius to one mile; but with the high-pressure system the area is practically unlimited in extent. When the mains and feeders are at high pressure, and the distribution at low pressure by two wires, we must contemplate *sub-stations* serving areas having a radius not exceeding 220 yards, if the lamps be uniformly scattered over the area and our waste energy is kept low.

A transformer sub-station is a very simple and cheap structure. It may be excavated underground, or be in a cellar or in a backyard. The instruments are stationary. They require no oiling, nor adjusting, nor handling, nor even tending. They can be buried in oil and suffer no deterioration. They are simple in construction, and should need no repair. Switches to throw them in and out of circuit may be automatic or manual, and can be operated from outside the transformer room, as is done in Rome. It is impossible to serve economically a wide and scattered district with a mean radius of over one mile by any other means than by high pressure, for we cannot multiply central stations without seriously increasing capital outlay and working expenses; unless, indeed, the density of supply be very great, as it is in some quarters in London and in some of our large provincial cities.

At the meeting of the Institution of Electrical Engineers, held on the 14th inst., a discussion took place on Mr. Preece's paper.

Mr. Swinburne remarked that in 1889 he had discussed the subject of disturbance in telephones with reference to concentric cables earthed at one end. Many persons thought no trouble would arise from such a course. This, he believed, was a mistake, for the outside conductor being near earth had a considerable capacity relatively thereto. If a large current, say, of 250 amperes, was passing, the pressure between the two ends of the outer conductor would be about 210 volts, and this would cause a considerable earth current to surge backward and forward between London and Deptford. The effect of these currents had, he believed, not yet been observed, but it would become noticeable when the load got heavy. Mr. Preece, he said, thought earthing the secondary of a transformer tended to lead the current into temptation, but, as a matter of fact, the temptation was diminished by earthing the middle of the secondary. If this be done neither secondary main could differ by more than 50 volts from the earth potential, whereas, if one end be earthed or neither, the risk and danger were considerably increased.

The further discussion was adjourned.

ON THE MOST ECONOMICAL MODE OF FEEDING A LOW-PRESSURE NETWORK.†

The advocates of alternating transformer systems of distribution appear at last to be in agreement with those who designed low-pressure systems, in that they admit that for the supply of towns of ordinary compactness a low-pressure network must be provided. As it was evident that there is a certain length of feeder at which the low-pressure direct system fails to compete successfully in first cost and that of upkeep with the above-described high-pressure A.T. feeder, I have recently investigated the question in order to find out at what mean length of feeders the low-pressure and high-pressure systems compete on equal terms of first cost, cost of upkeep, and efficiency. The result of my investigation is to show that when a three-wire low-pressure system, distributing direct to 110-volt lamps, is compared with an A.T. system, distributed by 2,000-volt feeders, transformed to supply the same three-wire network, the average annual efficiency of the feeders in both cases being 90 per cent., the low-pressure feeder is cheaper for all distances up to 2,400 yards, each of the feeders being calculated to supply 100 kilowatts; and the annual cost for upkeep, including a sum of 5 per cent. for interest on the capital, will be about £290 per annum. These large figures lead me to compare with them the known cost of upkeep of feeders carrying the same load which are now in use in London. I find that feeders of an average length of 600 yards cost about £300 each, and for interest and upkeep £25 per annum. This comparison shows that if we increase the length of each feeder by 1,800 yards, or say one mile, it increases the supply company's annual upkeep charges by not less than £260 per annum per feeder. If we apply these figures to a company supplying a district of about a square mile, which, if it had within it two generating stations, could feed its network with ten short feeders, and substitute for these two central stations one external generating station one mile distant from the outside

* Abstract of a paper read on the 7th inst. before the Institution of Electrical Engineers by Mr. W. H. Preece, F.R.S., Past-President.

Digitized by Google

of the district, the extra cost of upkeep of the ten long feeders will be £2,600 per annum. At a load factor of 10 such a district would sell 876,000 units per annum; therefore, the above sum of £2,600, divided by this number of units, is equal to 0·72 of a penny per unit sold. Now, even at present the cost per unit for coal and ground rent (which are the only two items affected by the removal of the site from a central position to a distant point) only slightly exceeds 1d. a unit, and in all probability during the present year this figure will be brought down to a sum approximately the same as the above-mentioned upkeep of the feeders—viz., 0·72d., which I have shown is the actual cost of upkeep of the feeders only. This shows the absurdity of imagining that any saving can be effected by this mode of feeding a network, and it is quite evident that those who have advocated the system have never seriously looked at the matter from this point of view.

THE MANUFACTURE OF SOAP.

By W. Lawrence Gadd, F.I.C., F.C.S.

X.

(*Concluded from page* 499.)

Apart from the best transparent soaps, some of which are almost everything to be desired, there is no doubt that the best soaps for toilet use are those manufactured by the "milling" process, which has only recently received any attention in this country, although it has been for some time generally adopted on the Continent. The process is practically the same as that followed years ago for the manufacture of the highest priced and

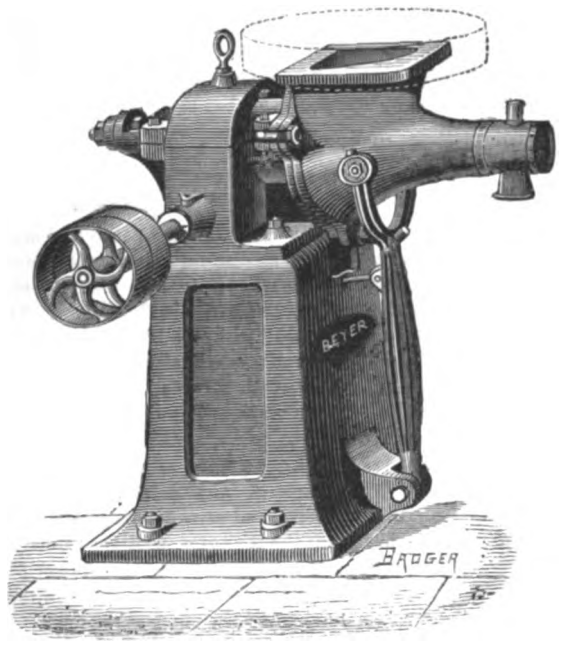

Fig. 15.

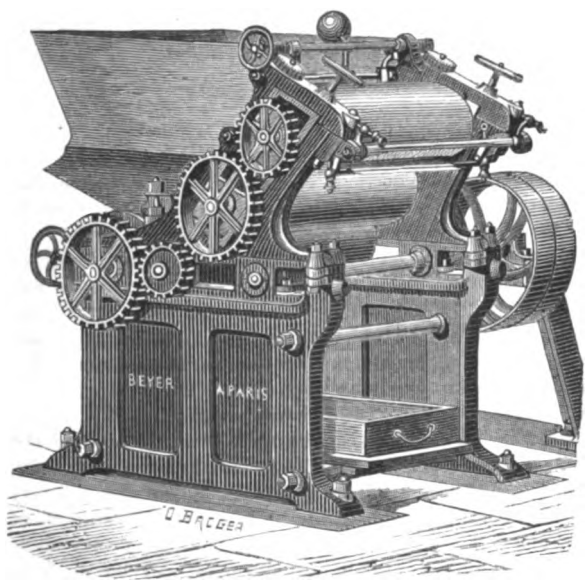

Fig. 16.

best toilet soaps, but with this important difference, that whereas the old result was attained by slow and careful manipulation by hand, in the new process, as its name implies, the skilled workman is superseded by powerful machinery.

Figs. 15 and 17 show the various necessary machines, as made by Messrs. Beyer Frères, of Paris, and supplied in this country by Messrs. Martin Perls & Co., of London. Their use may be briefly described as follows:—The bars of well-made, pure white, curd soap—which should be manufactured from the finest materials, and be entirely free from uncombined alkali and other objectionable substances—are first reduced to thin shavings or shreds by a belt-driven machine containing revolving knives, and called a rotary cutter, the bars being placed in the side hoppers, and the shavings delivered at the bottom of the machine. These shreds are then placed in the hopper of the crushing mill Fig. 17, where they are crushed to a pasty condition by passing several times between heavy granite rollers, while perfumes and colouring matter are at the same time added. In this way a uniformly coloured and homogeneous paste or dough is obtained, which is then transferred to the squeezing machine Fig. 15, where it is forced, by a special form of mechanism, through a tube or cannon, and thereby compressed or moulded into the form of continuous bars, which are made either round, flat, or square by passing through gauge plates of the required shape placed at the mouth of the cannon. The continuous bars so formed are cut into pieces of the desired size, and immediately stamped, the force of the downstroke giving the tablets the required shape and impressions, and also imparting a high finish or gloss to the surface. They are then ready, without further drying or manipulation, for packing or for use.

Fig. 16 shows an improved form of crushing mill, with four rollers; two of these are placed obliquely above the first couple, placed horizontally. The soap shavings are

THE MANUFACTURE OF SOAP.

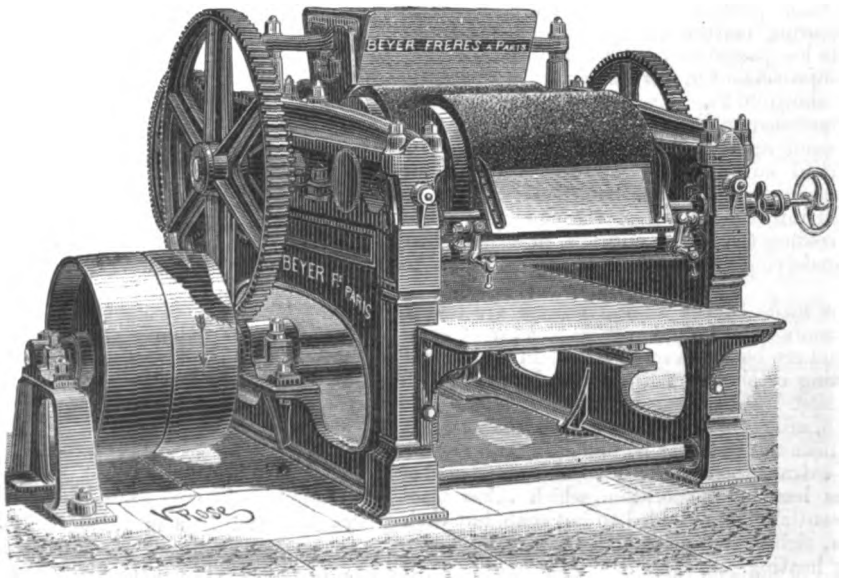

Fig. 17.

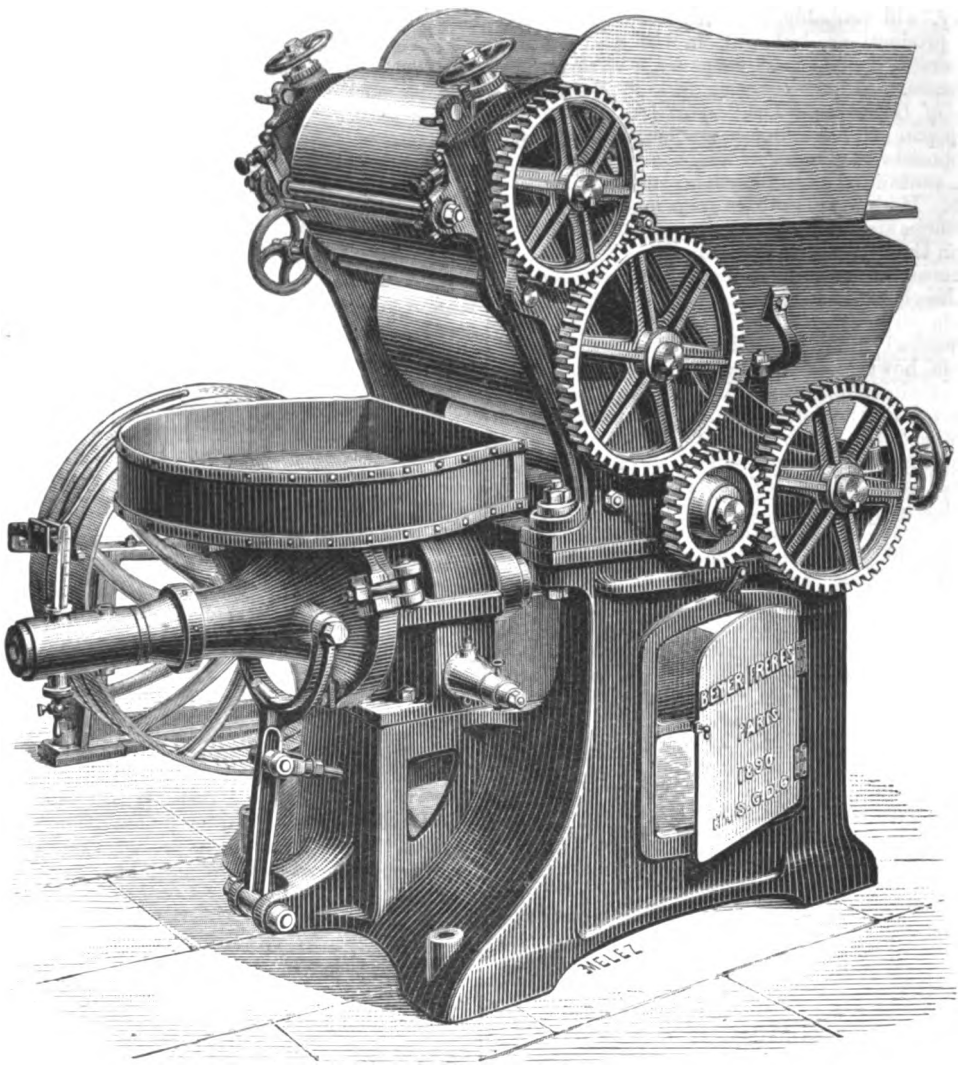

Fig. 18.

Digitized by Google

placed in the bottom hopper of this machine, and the paste or dough is worked gradually and automatically upwards through the rollers until it falls into the top hopper, the slide bottom of which is then drawn, and the paste falls into the lower hopper, to be again passed through the same process. This is repeated several times, the colouring matter and perfumes being added after the paste has passed through the mill once.

A further improvement in this machinery, and recently introduced, is shown in Fig. 18, and consists of the aforementioned four-roller, oblique crushing mill, combined with the squeezing apparatus, in one machine. The soap dough is worked automatically upwards through the rollers as described, and, when sufficiently milled, is allowed to fall into the hopper of the squeezing apparatus, thus avoiding the labour and loss of time consequent on transferring the paste from one machine to the other.

Toilet soaps made by the milling process are manufactured in a more scientific manner, have a far superior appearance, and are better in every way than those made by the remelting or similar methods as at present still largely practised. They have a beautiful glossy and wax-like finish, are more delicately and brightly tinted, and the perfumes can not only be added in larger quantity without extra expense, owing to the avoidance of the enormous loss by evaporation, which takes place when the essential oils are added to hot soap, but their odour is finer, richer, and more lasting, because unimpaired by any heating.

The soap, which contains only a minimum quantity of water, is perhaps more pleasant to use than any other, producing at once a fine creamy and persistent lather, and, although only recently introduced to any extent in this country, will probably not only take preference over other productions, but will, in the near future, entirely supersede opaque toilet soaps made by any other existing process.

Recovery of Glycerine.—The "spent lye," drawn out of the soap pan after the first operation, as previously described, consists of a more or less concentrated solution of salt, containing a comparatively small percentage of glycerine. It also generally contains small quantities of soap, resinous and albuminoid matters, and impurities derived from the original fats or oils.

The processes in use, of treating the lye for the recovery of the glycerine—which forms the valuable constituent—are all protected by letters patent, and are generally worked under royalties. The principle of most of them, however, is to eliminate the organic impurities by precipitation with acids and other substances, and to get rid of the large quantity of water, which forms the bulk of the lye, by evaporation; the salt being at the same time precipitated thereby, and from time to time removed and dried for further use in the soap pan. The concentration is effected in various forms of pans, heated by fire, and in cylindrical or other shaped concentrators, in which the descending stream of lye meets a blast of hot air, or is allowed to flow over heated surfaces. When sufficiently concentrated, by any of these means, an impure, dark-coloured glycerine is obtained, which is often sold by the soapmaker in the crude state, but is sometimes further purified at the soapery, generally by heating with animal charcoal and distilling several times with superheated steam.

The large quantity of water which has to be evaporated is the great difficulty in recovering glycerine from spent lye, it often requiring, in an ordinary sized pan, ten or twelve days to concentrate the lye; and there is is little doubt that the future method will be to decompose the neutral fats into glycerine and fatty acids, the former of which will then require little or no purification, whilst the latter will be placed in the soap pan and converted directly into soap.

Notes.

THE COALFIELDS OF TEXAS.

A RECENT report contains some very interesting facts about the coal measures of Texas. The main lead of bituminous coal is first met with in the northern part of the State, and extends south-west from a point on Red River, in Montague county, to the Colorado, being a continuation of the western field, of which it is the southern boundary. This deposit underlies twenty-five counties and covers an area of 12,000 square miles. Thus far, says the *Age of Steel*, this deposit has been unworked, with the exception of that portion located in Erath county, which has been developed on a small scale by the Texas and Pacific Coal Company. The deposit ranking next in importance is on the Rio Grande River, and underlies Medina, Zavalla, Webb, Uvalde, Maverick, and Dimmit counties, embracing an area of 3,700 square miles, and is known to geologists as the Neuces coalfield. The coal mined is of a semi-bituminous character in the lower strata, while in the upper strata it is of the lignite order. The principal developments are at Santa Tomas, in Webb county, near Laredo, and at Eagle Pass, in Maverick county. Splendid deposits of lignite are found in Red River county, extending south-westerly to the Rio Grande, and north-east to the Sabine, in Sabine county, the only developments thus far made being in Rains county. The quantity of coal mined in Texas during the years 1888 and 1889 aggregated 128,216 tons, and its value is estimated at about £68,000.

AN AGRICULTURAL COLLEGE IN VICTORIA.

EARLY last month the foundation stone of a new College of Agriculture was laid at Mildura, in Victoria. This college is being built in connection with the Australian Irrigation Colonies which were founded some years ago by Messrs. Chaffey Brothers, and will play an important part in affording facilities for imparting the necessary instruction in irrigation and its dependent industries in Victoria.

SMALL CELLS FOR ELECTRICAL WORK.

THE demand for a small battery is as great as ever, and there seems a likelihood of one being supplied soon. What is wanted is a cell for laboratory work, which is at once cheap and durable. Some American papers advertise a very minute chloride of silver cell, arranged to give 2 amperes and 1½ volts, presumably on closed and open circuit. Messrs. Hartmann & Braun, Gassner, and others are putting on the market compact "dry" cells. A set of 100 tiny cells in a really portable case would be most valuable for insulation, testing, and similar work.

A SIGN OF THE TIMES.

THE session of the Institution of Electrical Engineers is practically now over, and there is a general feeling among the members that it has been dull and non-productive. Except Mr. Crooke's address, the papers read have not been of first-class importance, and, odd as it may seem, this may really be a very good sign. The members are so busy doing practical work just now that they may have little time to devote to working out new ideas or writing papers about them. If this be the case, may we have another dull session next season!

ENGLISH LOCOMOTIVES IN AMERICA.

THE Webb compound locomotive, imported about two years ago by the Pennsylvania Company as an experimental engine, and which, judging from the newspapers, failed over and over again, seems, according to our contemporary *Industry*, of San Francisco, to be working trains very successfully between New York and Philadelphia. It hauls seven cars, makes seven stops, and does a 90-mile run in 124 minutes, burning, as reported, 25 per cent. less fuel than is used in the other engines. The importation of this engine and the results it has led up to have been features of interest in America. It has caused the above-named company to construct a number of "express compounds," all of which have proved very satisfactory, as is shown in the recent tests on the Baltimore route.

ALABAMA COALFIELDS.

THE three principal coalfields of Alabama are, according to the *Engineering and Mining Journal*, the "Warrior," "Cahaba," and "Coosa," of which all exhibit a south-west pitch or slope. The special features of the "Warrior" field, 7,810 square miles in area, are, first, a tendency in all coal seams to thin going north-west from the south-east outcrop, a line of average thickness crossing the field diagonally in a north-east and south-west direction; second, an increase of hardness in the same direction with a corresponding decrease of coking properties, so that the typical coking and smithing coals are mined along the south-east outcrop, while the best domestic and shipping coals come from the centre and west; third, a nearly constant chemical composition, commercial lots averaging—fixed carbon, 55 per cent. to 63 per cent.; of volatile matter, 28 per cent. to 34 per cent.; ash, 5 per cent. to 10 per cent.; and sulphur, 0·5 per cent. to 2 per cent. The moisture in all Alabama coals is low. The "Cahaba" field, as at present developed, produces the best "all around" fuels in the State, but in the northern end of the basin the coal appears dirty and slaty, and the productive areas in the south end are limited by reason of high dips and the broken and disturbed condition of the measures. The "Coosa" field has only two active operations, which, in point of production, are of minor importance. The coking coals of the district will naturally continue to be drawn from the present developed areas. The needs of the district for domestic and steam coals will best be met by the construction of a north and south railroad from Tuscaloosa, passing through the heart of a rich coal area, where the measures are thickest and coals situated favourably for economical mining.

PELTON WATER WHEELS.

MR. ROSS E. BROWNE, of the University of California, has, according to the *Engineering Record*, published some interesting figures derived from tests of Pelton water wheels made at the University. According to these tests, a wheel 15in. in diameter and 1·5in. wide, working under a 50ft. head, the nozzle being $\frac{7}{16}$in. in diameter, showed an efficiency of 82·6 per cent. When the nozzle was ⅜in. in diameter, the efficiency was 82·5 per cent. On reducing the head to 8ft. the efficiency was 73 per cent. To obtain a high efficiency with these wheels, Mr. Browne states that the bucket surface at entrance should be approximately parallel to the relative course of the jet, and the bucket should be curved in such a manner as to avoid a sharp angular deflection of the stream. The number of buckets should be small, and the path of the jet in the bucket short to keep down the frictional resistance. The discharge end of the bucket should be as nearly tangential to the wheel periphery as is compatible with the clearance of the bucket. The speed of the buckets should be half that of the jet.

IRON AND STEEL WORKS IN CHINA.

As we stated in our issue of the 1st inst., iron and steel works for the construction of steel rails for railways, steel for gun founding, and mercantile iron have been begun near Hanyang on the western bank of the Han River. The masonry for blast furnaces, both by the Bessemer process and by the Siemens-Martin process, is being rapidly constructed, and machinery from England has been ordered. Much of the machinery has arrived at Shanghai, and is only waiting for the river to rise to be brought to Hankow. In February there were two locomotives at the works, and about three-quarters of a mile of railway laid. The works are situated on the River Han, and arrangements are being made to have a jetty on the Yangtze, a little above its junction with the Han. The ground will be raised 6ft. above the highest flood level of the Yangtze. It is contemplated, in the first instance, to turn out 100 tons of steel rails per day, and ultimately to increase the output to 200 tons a day. This is exclusive of mercantile iron and steel for guns. The ground to be covered by the ironworks is 2,728ft. by 500ft., or more than 30 acres. Good iron ore has been discovered at Huang Kang, about 15 miles down the river, and 20 miles inland.

ELECTRICAL SUB-STATIONS.

THOUGH most electrical engineers have come to the conclusion that house transformers are a mistake, there is a difference of opinion as to what a sub-station should be. From an assumption that ordinary small transformers give efficiencies approximating to 98 per cent., there has been an oscillation over to the opinion that even large transformers are so bad that they must be banked. We describe in another column a most ingenious apparatus for cutting transformers in and out. Such an apparatus may be necessary with existing transformers, but if half the brain-work involved in designing it were devoted to the study of transformers, banking, with its attendant evils, would be unnecessary. In designing central stations very serious mistakes may be made by adopting sub-stations of this sort. There can be no doubt that in a very short time even closed circuit transformers will be made so efficient that cutting them out of circuit during the day will not be worth while, and engineers will find they have marred their designs to meet an obsolete requirement. They will then find that they have rents to pay, complicated mechanism to look after, and that the independent feeder system is inapplicable unless they have an attendant at the sub-station. There can be no advantage in banking transformers, and a transformer at the end of a high-pressure feeder, placed in oil in the ground, is capable of controlling the lighting arrangements of a whole town, whatever its size, by means of feeders and networks.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

11th May, 1891.

8039. Lindley, R. H. N. ..... Wheel valves.
8041. Jefferson, Jefferson, & Jefferson ..... Fans or rotary blowers.
8042. Billington & Newton... Asbestos packed cocks.
8050. Robinson, T. ..... Machinery for hoisting.
8053. Hawksworth, C. W. R. An electromagnetic stop motion applicable to machinery used in spinning.
8057. Naylor, C. H. ..... Valve gear.
8060. Downham & McCrannor Drills.
8062. Davis, G. ..... Hydraulic weighing machines.
8063. Russell, E. ..... Railway signalling apparatus.
8067. Kentman & Bach ..... Apparatus for charging and discharging gas retorts.
8069. Capitaine, E. ..... Gas engines.
8070. Crapter, W. ..... Platen printing machine.
8071. Fitzmaurice, C. H. ..... Means for utilising petroleum with steam for heating purposes.
8078. Ellis, J. D. ..... Steam boilers and their furnaces.
8079. Johnson, J. Y. ..... Radial axle boxes for railway or tramway vehicles (*Weidknecht*).
8080. Phillips, W. ..... Air jet draught inducer.
8081. Stone & Clark ..... Meter for measuring liquids.
8086. Collins, E. ..... Apparatus for testing water meters.
8091. Imray, O. ..... Fastenings and supports of railway rails (*Rottes*).

12th May, 1891.

8095. Brock (of the Firm of Denny & Co.) & Weir Marine steam engines.
8098. Taylor, G. P. ..... Divided flexible shaft.
8100. Dunn & McLewin..... Water, steam, or other cocks.
8103. Webster, D. ..... Regulator for reeling machines.
8125. Rogers, C. D. ..... Slotting screw heads and dies therefor.
8129. Richards, W. G. ..... Mould for casting steel wheels.
8145. Bason, R. W. ..... Steam engines.
8146. Boult, A. J. ..... Method and means for retarding vehicles (*Ries*).
8148. Boult, A. J. ..... Riveting apparatus (*Ries*).
8164. Lake, H. H. ..... Air compressors (*Hill*).
8167. Gates, R. D. ..... Concentrating apparatus.
8168. Dalby, W. E. ..... Valve gear for locomotive and other engines.

13th May, 1891.

8178. Pardon, A. J. ..... Brakes for wheeled vehicles.
8186. Heys, W. E. ..... Balance slide valves (*McDonald*).
8190. Wilks, J. F. ..... Signalling apparatus.
8193. Booth, W. ..... Friction clutch.
8199. Broughall, E. H. ..... Machines for drilling the hubs of cycle wheels.
8211. Sherwin, G. E. ..... Cutting tools and holders.
8217. Sennett, A. R. ..... Combustion of smoke in furnaces.
8219. Sennett & Cannon ..... Pumps.
8230. Martin, J. H. C. ..... Wood wool machinery.
8235. Causer, W. G. ..... Hydraulic jacks.
8237. Watts, J. R. ..... Drills for boring and reaming.
8238. Taylor, G. B. ..... Machines for planing metals.
8241. Horn, W. W. ..... Speed indicator (*Berry*).

14th May, 1891.

8249. Pizzey, W. J. ..... Spring rim for wheels.
8251. Barrett & Tichhurst ... Motor engines.
8253. Hadfield, F. J. ..... Vacuum brakes.
8257. Whittaker, J. ..... Taking-up motion for looms.
8262. J. Webb & Co. ..... Back pressure valve.
8268. Wilson, J. H. ..... Bobbins for spinning frames.
8277. Carrick, J. ..... Boiler furnaces.
8289. Hardingham, G. G. M.... Rotary engine (*Cleland*).
8309. Smith, A. ..... Printing machines.

15th May, 1891.

8329. Guthrie, H. ..... Driving chains and wheels.
8355. Liebert, H. (on behalf of John Holroyd & Co., Ld.) ..... Split spiral milling cutters.
8357. Taylor, S. ..... Combustion of fuel in the furnaces of steam boilers.
8359. Dickinson, A. ..... Cable tramways.
8360. Musgrave, Jun., & Crompton ..... Stuffing boxes.
8364. Smith, A. W. ..... Cycle, engine, and other wheels.
8366. Richmond, G. H. ..... Feeding bottles.
8368. Johnson, J. ..... Chain - welding apparatus (*Baker*).
8379. Walther, W. ..... Steam boilers.
8385. Hopkinson & Hopkinson Valves.
8389. Robinson, S. ..... Slide valves.
8396. Stewart & Pugh ..... Machines for producing oval, elliptic, or other work in wood.
8404. Phillips, A. K. ..... Drilling machine.
8409. Price-Williams, R. ..... Permanent way of railways (*Moncrieff*).

16th May, 1891.

8417. Dickinson, E. ..... Propellers applicable to navigable vessels.
8429. Morton & Findlay ..... Steam boilers.
8432. Ridealgh & Brewis ..... Device for facilitating the centreing of work in lathes.
8433. Merrywrather & Jakeman ..... Couplings for hose-pipes.
8435. Merrywrather & Jakeman ..... Rotary pumps.
8438. Cowan & McArthur ... Gas valves for steel furnaces.
8441. Bell, R. ..... Signalling on railways.
8449. Burnet, L. ..... Steam boilers.
8452. Sturgeon & Crampton... Stop valves.
8453. Tracy, L. J. ..... Drum governors.
8454. Duffield, White, Reading, & White..... Faced rail for railways.
8469. Abel, C. D. ..... Gas and oil engines (*The Gas Motoren Fabrik Deutz*).
8471. Shand, W. F. ..... Manufacture of steel.
8486. Lake, H. H. ..... Motors for driving sewing machines (*Caspani*).
8487. Sheldon, A. ..... The manufacture of paper pulp.
8489. Smith, W. F. ..... Lathes.
8493. Dalifol, M. ..... Moulding machines.

ELECTRICITY.

11th May, 1891.

8048. Kennedy, R. ..... Dynamo-electric generators.

12th May, 1891.

8102. Aspinall & Hoy ..... Electric signals.
8126. Philpott, G. J. ..... Compound dynamo - electric generators.
8136. Christiansen, J. ..... Car motors.
8141. Thompson, W. P. ..... Insulated conductors (*Williams*).
8150. Siemens Brothers & Co., Ld. ..... Rotary phase alternative current motors (*Siemens & Halske*).
8152. Siemens Brothers & Co., Ld., & Williamson ... Means for heating metal rods or wires for making nails, screws, key-blanks, &c.
8153. Siemens Brothers & Co., Ld. ..... Means for carrying electromotors on electric cars or vehicles (*Siemens & Halske*).
8163. Dewey, M. W. ..... Electric railways.

13th May, 1891.

8198. Housman, Dixon, & Holden ..... Meter.
8218. Sennett & Cannon ..... Dry batteries.
8225. Aspinall & Hoy ..... Controlling signals by electricity.
8227. Thompson, W. P. ..... Accumulators (*Tudor*).

14th May, 1891.

8256. Renouf, P. L. ..... Electrical brazing.
8323. Goldsmid, J. ..... Thermo - electric apparatus (*Riatti*).

15th May, 1891.

8378. South, H. ..... Resistances.
8390. Takashima, S. ..... Electrical signalling apparatus.
8397. Taylor, W. F. ..... Alternating current dynamo generators.
8412. Johnson & Phillips..... Armatures of dynamo-electric machines.

16th May, 1891.

8450. Snell, C. S. ..... Conductors.
8457. Spokes, G. A. ..... Arc lamps.
8492. Perlovsky, V. ..... Electromotors.

CHEMISTRY.

11th May, 1891.

8064. Gutbier, J. C. F. ..... Vat dyeing process.

12th May, 1891.

8161. Lake, H. H. ..... Manufacture of white lead (*Dahl*).

14th May, 1891.

8311. Chambers, Hodgson, & Hammond ..... Manufacture of white lead.

15th May, 1891.

8344. Bowman, W. ..... The treatment of phosphate of alumina (*Bowman*).
8407. Pitt, S. ..... Blue dyestuffs (*L. Cassella & Co.*).
8415. Warwick, A. W. ..... Extraction of antimony from its ores.

16th May, 1891.

8470. Bamberg, G. ..... Manufacture of silicate of soda and carbonate of soda.

MISCELLANEOUS.

11th May, 1891.

8052. Grayston, A. J. ..... Instrument for ascertaining levels, perpendiculars, and gradients.
8082. Barbat, A. ..... Lubricators.
8083. Mond, L. ..... Manufacturing nickel alloys.
8084. Lockwood, H. ..... Purification of sewage.
8087. Cullen, W. H. ..... Covering for boilers, steam pipes, and other surfaces.
8090. Gehring, G. ..... Enamel for metals.

12th May, 1891.

8115. Draper, J. ..... Preventing incrustation in steam boilers.
8124. Shawcross, E. H. ..... Locking devices for bolts and nuts.

13th May, 1891.

8180. Brown, A. O. ..... Regenerative gas lamps.
8205. Killick, G. E. ..... Pipe joints.
8234. Davis & Baldwin ..... Joint for coupling pipes.

14th May, 1891.

8319. Rigg, J. ..... Packings.

15th May, 1891.

8330. Saville & Hulme ..... Placing tubes on spindles used for spinning.
8358. Gelder & Crosland..... Shuttle pegs for shuttles.
8381. Watson, J. R. ..... Making moulds for casting.

16th May, 1891.

8426. Birch, W. ..... Cleansing sewage.
8474. Radford & Hallam ..... Nut-locking devices.
8496. Price, J. ..... Treatment of sewage.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

7247. Baudouin & Escarpit.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

WIRE ROLLING.—*H. A. Williams, Taunton, Mass., U.S.A.*—It is claimed that by the method of cold-rolling practised according to this specification, wire may be produced, of any desired section and gauge, which will not require annealing after the operation of rolling, for the process described is said to have an actual annealing effect, so that rods originally quite hard, and with but little malleability, come out after the successive reductions annealed and with their tensile strength increased. The main idea in the present instance is to avoid the mode of handling the wire adapted in ordinary rolling processes, wherein the wire is considerably altered in some parts at one stage of the operation and but little affected in other parts, whereby severe internal strains are set up in the metal by this irregular deformation, which ultimately disrupt it. The inventor arranges the successive rolls so that the wire is compressed, not along separate diagonals in succession, but along several radii simultaneously; this result is obtained by using a train of rolls, the grooves of which have their surfaces substantially parallel throughout the train, the bottoms of the grooves in each pair terminating in a flattened or truncated portion, whereby the width of the space included between the pair of rolls is less, measured between the bottoms of the grooves, than the width at the tops of the grooves, the width between the bottoms of the grooves of a given pair being equal to the width at the top of the grooves in the next following pair. Claims: The arrangements substantially as described, for the purpose of displacing practically equal amounts of metal at all points acted upon by the rolls.—No. 2898. February 17th, 1891. 8*d*.

FLEXIBLE COUPLINGS.—*G. F. Redfern & Co., London.* (*F. Wolseley, Sydney, N.S.W.*)—The flexible couplings described in this specification are those employed in connection with toothed wheel gearing, which are sometimes termed "universal gearing joints," and which are arranged so as to allow of the angle between spindles of the gear wheels being varied whilst the gearing is at work. The particular improvements under this patent consist in the combination and arrangement with the sleeves of the spindles (which sleeves have flanges or heads to protect the toothed wheels) of a male and female lug on opposite ends of an extension of each of the sleeve flanges. These pairs of lugs are so arranged that when the two portions of the coupling are placed together, with the protector flanges face to face and the two spindles in line, the opposing lugs will "take" one within the other, and keeps or wards thereon will be in juxtaposition, so that when next the coupling is opened out the two halves will be locked together. The gear wheels employed are crown wheels, and are put on to their spindles and firmly secured thereto after the coupling is opened out as aforesaid. The presence of the two gear wheels prevents the two halves of the couplings from being brought into the position in which uncoupling may take place, and therefore, before such operation can take place, the wheels must be removed from their spindles. Claims: An arrangement of universal gearing joint as described, in which the unlocking of the joint is prevented by the presence of the gear wheels, and in which the joint is formed by male and female lugs interlocking with and turning upon one another.—No. 4210. March 9th, 1891. 6*d*.

CENTRIFUGAL MACHINES.—*J. Sellars, Derby.*—This invention describes improvements in what are known as continuous centrifugal machines, employed for drying sugar and other granular substances, and for separating solid from liquid substances. The periphery of the basket or drum is, according to this invention, composed of a number of vertical sections or vanes, free to rotate when desired. These vanes are perforated, and permit liquids to pass from the rotating basket into a rotating casing retaining the solids until such time as the vanes are rotated on their own centres, whereupon, through the openings thus provided, the solid residue is flung out through openings in the rotating casing into a receptacle which is separate from that into which the liquids previously issued. Figs. 1 and 2 below illustrate in plan and vertical section respectively one modification of the apparatus, which may be thus described:—To a revolving solid spindle A is secured a casing B, the upper portion C of which may be a casting of suitable material carried by the sleeve D of the spindle

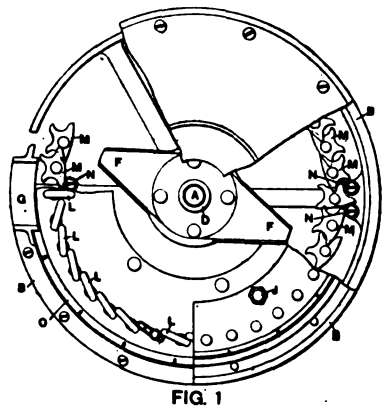

FIG. 1

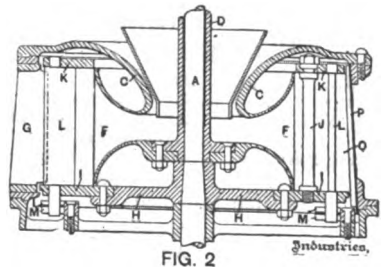

FIG. 2

A, the centre being dished or curved downwards and leading to two shoots or spouts F. The sides of the casing B are made of sheet metal with openings as at G, through which the solids are discharged into a "monitor" casing not shown in the illustrations. The basket or drum is secured to the revolving spindle A, and is composed of a bottom plate H supporting a steel ring I, into which are fixed a number of pillars J supporting at their upper ends another steel ring K, these rings I and K being the supports for a number of vanes L as above described. The casing and also the frame supporting the blades revolve in such a manner that they pass the openings G at a suitable speed, and during the time of passing these openings the blades or vanes partially revolve and allow the dried substances to pass out. As soon as the blades have passed the openings they are again closed, before coming opposite to the spouts or shoots through which the combined substances are admitted to the inside of the basket or drum. The vanes are opened and closed at the proper times by cams M which are carried upon extensions of the vanes so as to come into contact with and be operated by fixed studs or rollers N carried by the outer casing, which, although it revolves, does so at a slower speed than the basket, this diferential motion being obtained by any suitable arrangement of gearing, and being adopted for the purpose, affording the time necessary for drying the material operated upon, by causing the intervals at which the vanes are operated to be longer than would otherwise be the case. The liquid discharged through the perforations of the vanes passes into the annular space O between the vanes and the sides of the outer casing. In the latter are fixed diagonal ribs P to accelerate the discharge of the liquid into the receiving gutter. Other arrangements of discharge vanes are described, opened and closed by cams as above. Claims: The vanes, pockets, and the like forming the periphery of a drying or filtering drum, as described; the mode of operating the vanes by cams; the two casings revolved at different speeds by differential gearing; the diagonal ribs as described in the last paragraph; the apparatus as a whole and its modifications as described.—No. 10461. July 7th, 1890. 8*d*.

STEAM PUMPS.—*J. N. Floyd, Handsworth, Staffs.*—In many pumping engines where the valves are operated by the motive fluid, it has been customary to admit the latter fluid to the cylinders in which the pistons of the valve are situated, through perforations made through the said pistons, and to obtain access to the said perforations the engines have to be stopped and the covers removed. To obviate this the arrangement illustrated below has been designed, and is shown as applied to the steam

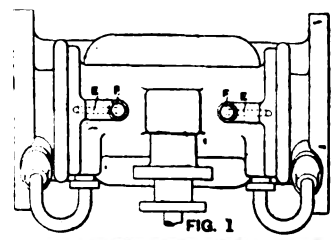

FIG. 1

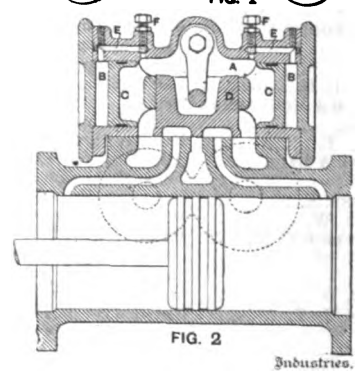

FIG. 2

cylinder of a Tangye's special pump, which, with its accessories, is shown in plan and section, from which its analogous applications will also be understood. Communication between the place A, whence the motive fluid to actuate the valve is obtained, and the cylinders B, in which the pistons C of the valve D are situated, is established by perforations E, made in the casting, and these perforations are each provided with a choking screw F or equivalent device, by which the area of the passages can be adjusted, the heads of these screws projecting outside the cylinder as shown. To prevent the screw or like device from being operated by inexperienced persons to completely close the passages and stop the engine, means are provided by which, when the screw has closed the passage to the fullest extent, there still remains a blow-through hole, by which passes sufficient steam to keep the engine working; or other arrangements than the blow-through passage in the screws may be adopted for a similar purpose. Claims: The passages arranged and regulated as described, for governing the admission of working fluid to the valve cylinders of the motive power cylinder of pumps.—No. 14619. September 16th, 1890. 6*d*.

RING SPINNING FRAMES.—*E. de Pass, London.* (*J. Imbs, Paris.*)—The improvements about to be described refer to means for building up on the slender and bare spindles conical self-acting cops of considerable height, and presenting the greatest differences of large and small diameters, from yarn of slight twist and little resistance; anti-ballooning apparatus stretches

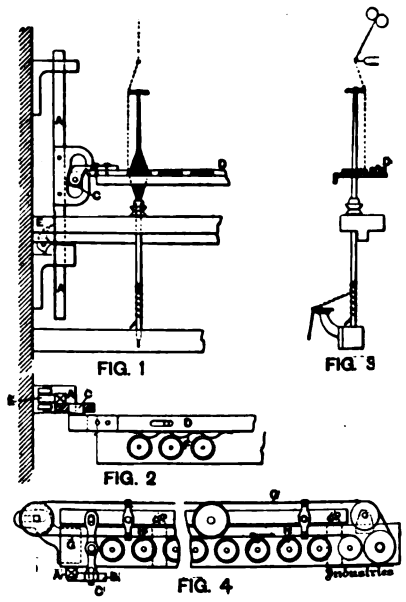

FIG. 1

FIG. 3

FIG. 2

FIG. 4

the yarn whilst it is winding upon large diameters of the cop. Figs. 1, 2, and 3 show in side elevation, plan, and cross-section, respectively, the anti-ballooning apparatus, in which the rod A carrying the cam-plate B operates by means of the roller C a bar D sliding longitudinally upon the copping-rail within limits determined by suitable stops. With the copping-rail in its lowest position, when the commencement of the winding occurs, the rod A will depend from the roller C, and rack teeth at its lower end will be below the stationary detent E, and will not engage therewith until the vertical rise of the rod A exceeds a certain limit; thenceforward the rod is permitted to rise when lifted by the roller C, but is prevented by the detent E from following the falls of the rail; thus, at each fresh rise and fall of

Digitized by Google

the copping-rail the bar D will now receive a to-and-fro movement of an amount dependent upon the form of the slot in the cam-plate B. The side of the bar D facing the rings is provided with very flexible friction-pads F, and the movement of the rail during the formation of large diameters brings these pads against the rings G and impedes the travellers, thereby tightening and stretching the yarn, but during the formation of small diameters the pads F will be moved away from the rings. On the copping-rail, behind the rings, is an arrangement, illustrated in plan in Fig. 4, of continously driven endless band H, which is preferably arranged so as to bear against the travellers and assist them by giving them a portion of a rotation during each revolution and assisting the efforts of the yarn, which at such times is unfavourably situated for pulling. The endless band is brought against the travellers when necessary by a sliding bar similar to the bar D, and operated in like manner; or the bar D may operate both the retarding and the accelerating devices; or the endless band H may be operated as required by a pair of fast and loose pulleys regulated automatically; also, the acceleration may be applied direct to the yarn instead of to the ring or traveller, and the band H may be applied to the rings as a retarder. Claims: The accelerating and retarding devices operating upon the rings or travellers, or upon the yarn; a single or double arrangement of the bar D bringing into alternate operation the accelerating and retarding devices; the arrangement substantially as illustrated and described with reference to Figs. 1, 2, 3, and 4. —No. 2858. February 17th, 1891. 8*d*.

Gas and Petroleum Engines.—*A. G. Melhuish, London.*—The herein-described improvements in gas and petroleum engines comprise a method and means analogous to the compounding of steam engines, and it is stated that the economic effect is relatively greater. Fig. 1 is a sectional elevation, and Fig. 2 an end elevation, partly in section, of an engine constructed according to this invention, Fig. 3 being a sectional plan of the cylinder ends and passages. Two cylinders A and B are arranged either side by side or one above the other as shown in the illustration, and a port or passage C is provided from one to the other in such a manner that it is operated by a valve D which closes the said port at the same time that one of the cylinders is open to the exhaust. Two pistons E and F work in the cylinders A and B respectively, and are connected by suitable rods to two cranks G and H, each attached to separate shafts supported in bearings upon the bed-plate. The principle adopted is that both pistons

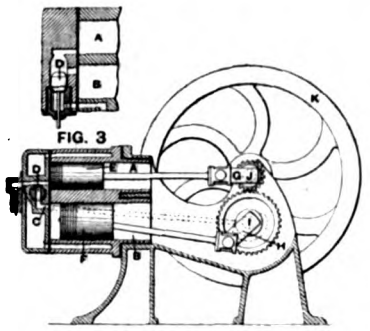

FIG. 3

FIG. 1

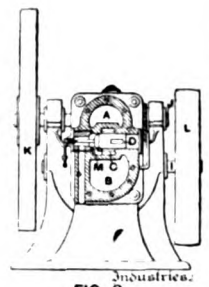

FIG. 2

may perform an equal amount of work upon the driving shaft I, which can be effected by making the piston E of half the area of F, the stroke of each being equal, but the shafts I and J being connected by gearing having the ratio 2 to 1, or the relative proportions of gearing, areas, and strokes may be otherwise arranged to attain the same result. It is preferred to attach the fly-wheel K to the shaft J, and the driving pulley L to the shaft I. The piston E makes two outward strokes and two return strokes to one double-stroke of the piston F, and the cranks G and H are placed so as to be at the position of half-stroke at the same time. The double-ported semi-rotary valve D is worked by a cam or eccentric, or otherwise, and is furnished with a screw thread of long pitch so that a longitudinal motion results from the semi-rotation of the valve and keeps it tight by the fitting of the conical end upon the seating M when the port of communication between the two cylinders is open, the valve opening the exhaust from the lower cylinder when the port of communication is closed, as shown in Fig. 2. It is an essential feature of the invention that one of the two cylinders arranged as described and shown acts as a motive power cylinder and as a pump alternately, while the other acts as a motive power cylinder only. Thus, the mixture in the example quoted is drawn into A by the piston E, and is exploded behind both E and F, the port C between the two cylinders being kept open; the igniting device, of any convenient type, is exposed to the charge by the travel of the pistons only, whereby premature explosion is obviated, and the cranks are so set that at the moment of explosion they are in the best position for receiving the impulse. The series of operations are performed as follows:—The piston E in cylinder A draws in a mixture of gas and air through a suitable automatic valve, the passage of inter-communication being closed, and the piston F being upon its instroke, expelling the products of combustion from the previous explosion through the exhaust port. The piston E on completing its instroke has pushed the mixture previously drawn in into B, the port of communication D having been opened when C reached the middle of its return stroke, during which time the crank H will have made approximately $\frac{1}{10}$th of a revolution from the dead centre. The igniting device is now uncovered by F, and the mixture explodes, giving an impulse to both pistons, and E will have commenced the second outward stroke. The return stroke of E forces the products of combustion from A into B, whence they are expelled through the exhaust port on the return stroke of F. The explosive charge is expanded, after ignition, to the same volume as before ignition in about one-third of the time necessary to procure such expansion in an ordinary gas engine. Claims: In a gas or petroleum motor, the employment of two cylinders with pistons of unequal areas in combination with two cranks of equal stroke upon separate shafts geared as aforesaid, one of the cylinders being used as a pump and both as motive power cylinders; compounding gas engines of the ordinary displacer type, so that the displacer performs the function of a four-cycle motor, and the working piston that of a two-cycle motor, both of equal power; the arrangement of valve shown used in a compound gas or petroleum motor.—No. 5192. April 3rd, 1890. 8*d*.

Water Tube Boilers.—*J. N. Paxman, Colchester.*—Enclosed within a suitable frame lined with firebricks are three or more groups of tubes, connected in series by suitable collectors, which will hereafter be more particularly described. Fig. 1 is a side elevation, and Figs. 2 and 3 are front and rear end elevations of a boiler constructed according to this invention. The lowest group of tubes—immediately over the furnace—are steaming tubes A, and all the groups are arranged to slope upwards as shown in the illustrations herewith; the next group are also steaming tubes, and are lettered B, but the upper group are steam drying tubes C. There may be any number of tubes in each group, arranged in rows, horizontally and vertically, parallel with each other. The

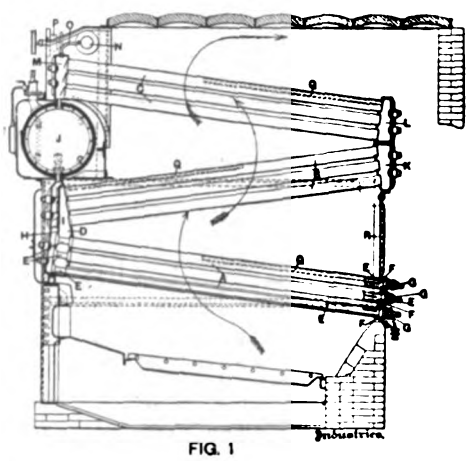

FIG. 1

tubes of the lower group of steaming tubes A are each independent and removable, and have freedom to expand; they are turned conical at both ends, and fit at the forward ends into collectors D D, and at their rear ends into junction boxes; they are kept in position by stay tubes E E, which are also circulating tubes open at both ends, and having at their rear ends longitudinal slots. The steaming tubes A are connected at the back of the boiler in pairs by longitudinal junction boxes F, forming in this example eight elements, and the adjacent tubes of each element are in communication with each other by joint boxes G, which are tightened down by a bridge piece and screw. Certain of the groups are connected by vertical boxes, as shown in Fig. 3, each filled with a suitable blow-off cock and pipe. The collectors D D are each divided into two chambers H and I, the former being in communication with the steam receiver J by nipples having conical joints tightened by nuts, similar to those which are used on the stay tubes. Suitable openings are made in the partition dividing H from I, opposite to each of the tubes B of the middle group, the openings being closed by discs which are secured in place, but which may be readily removed for the purposes of inspection and cleaning the tubes. The tubes B are expanded at both ends into the tube plates of the collectors, as also are the steam drying tubes C. The two groups of collectors K and L are alike, and are connected by suitable joints, easily removable, and the collectors M

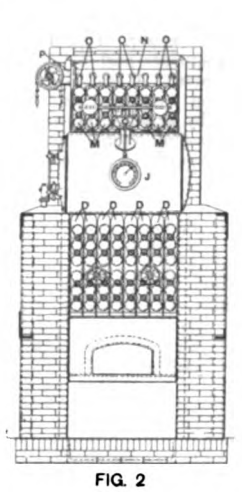

FIG. 2

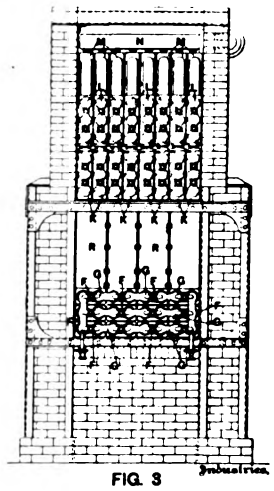

FIG. 3

communicate with the top of the steam receiver J by nipples with conical joints as already described with reference to the collectors K. In some cases these nipples can be fitted at the bottom with small valves adapted to shut automatically if, on account of a sudden and considerable consumption of steam, the water in the receiver should rise, with a tendency to prime. The steam collecting tube N placed above the highest group of tubes receives, by pipes O, the steam formed in each collector; these pipes are of small diameter, and their ends in the collector are reduced to a minimum in order to regulate the flow of steam in each element and get rid of suspended water. One end of N carries the stop valve P. Each of the groups of tubes is partly covered by angle irons Q, which form baffles and compel the products of combustion to follow a predetermined path, as indicated by the arrows in the illustration, and for similar purposes a partition R is provided to close the rear end of the boiler. The receiver J is not exposed to the action of the flames, being protected by lagging. Claims: In tubulous boilers, the arrangement of tubes disposed in three groups inclined in opposite directions as shown and connected, and working as described; the inner and outer tubes as in the lower group; the use of hollow stay tubes, slotted as described; the junction boxes, double collectors, discs opposite the ends of tubes B, and the arrangement of steam reservoir as shown, together with the general construction of tubulous boilers as set forth.—No. 8649. November 13th, 1889. 8*d*.

Spindles of Spinning, &c., Machinery.—*W. Sumner, Ghent, Belgium.*—The specification of this patent relates to improvements connected with the spindles and collars, or bearings therefor, used in machinery employed for the manufacture of cotton and other fibres. The collars, bushes, or linings are made from elastic metal, and afterwards tempered, or left untempered. They are formed as hereafter shown and described, so that a portion or portions of their outward surface act as springs, producing pressure against the inside of the frame collar or bolster, and other portions of the bush are formed to fit the spindle, so that, should the spindle or collar lining wear by use, the elastic portions of the bush will cause the bearing parts of the bush to fit the worn parts of the spindle, and prevent looseness or vibration of the latter. The bottom ends of the outsides of frame collars or bolsters, which have no linings, are reduced in thickness, and collar linings are extended below the collar sufficiently far for their lower ends to enter into oil or grease receptacles attached or fitted to the spindle (below the lifting part or traverse of the frame collars or of the stationary bolster) for the purpose of acting as an automatic lubricator to the spindle, collar lining, collar, or bolster. Figs. 1, 2, and 3 show flexible or elastic bushings for roving or preparing-frame collars; the tube is cut or slit from end to end, for example, helically, as shown at A, the parts which adapt themselves to fit the spindle being marked B; the parts C, which adapt themselves to fit the inside of the frame collar are formed with a suitable number of slits or perforations D in a helical or equivalent direction, thereby producing the spring parts C. Other forms of collar, suited to "Rabbeth" spindles, and flexible bushes for other types of spindle are described, being arranged on similar principles. Fig. 4 shows part of a roving spindle, with an oil or grease receptacle attached to the spindle at E. Fig. 5 shows an oil or grease receptacle for a mule winding or throstle frame spindle. Fig. 6 shows a preparing-frame collar reduced at its lower end F for the purpose of entering an oil receptacle fixed upon a spindle. Such method of lubrication enables a frame to work well by oiling the same, say, once per week, thus allowing

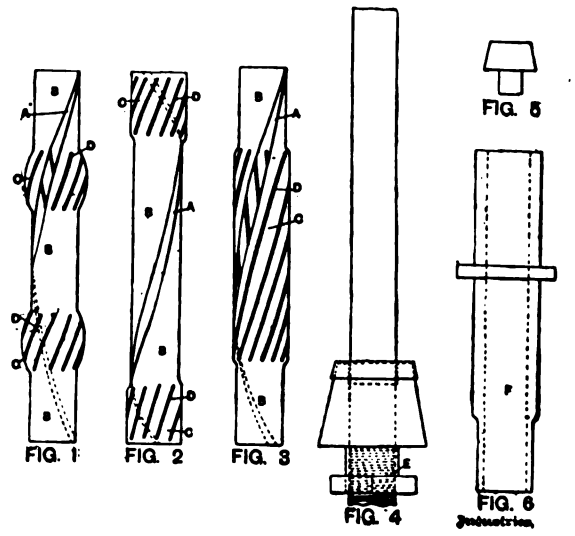

FIG. 1 FIG. 2 FIG. 3 FIG. 4 FIG. 5 FIG. 6

the frame to be more continuously in use, and preventing loss of time such as occurs by stopping the frame daily for oil. For preparing-frame collars an elastic bush may be formed from a spiral or helix of flat wire. Claims: Metallic collar linings or bushes, partially or wholly spring-like, and formed substantially as described; extending the bottom of collar linings, bushes, or hoops to below the bottom of the frame collar, whereby the hoop or lining in its descent enters an oil receptacle and lubricates the spindle bearing in its ascent; reducing in thickness the lower end of spinning frame and like collars, so that they may enter a lubricating chamber, for like purposes.—No. 8066. May 23rd, 1890. 8*d*.

Stock and Die.—*W. Horn, London.* (*J. Kreger & C. Rusbridge, Buffalo, U.S.A.*)—The object of this invention is the production of an efficient device for screw-threading pipes, rods, and similar articles, and especially one which may be used in confined positions, where the ordinary pipe-threading devices are inoperative. To attain these results the stock is formed with an annular body, and having a socket, into which is removably placed the end of a handle, the stock being also provided with a companion fixed handle. Upon the stock is located an upwardly projecting lug, having near its end a transversely arranged screw-threaded aperture to receive a correspondingly threaded spindle, having at one end a milled head and at the opposite end a button. Upon the stock, and upon both sides of the lug, are pivoted pawls, perforated to receive the screw spindle, and provided with springs to force the tail ends of the pawls away from the lug. In the annular portion of the stock there is a central aperture for the reception of the shank of the die-holder, which die-holder has an angular recess to receive a pipe-threading die and a passage for the pipe to be threaded. Below the head of the die-holder are formed a series of ratchet teeth, with which engage the ends of the pawls. Below the central portion of the die stock, and upon a conical shank, is located an annular disc, having cam-shaped recesses grooved to receive the toes of sliding cutter bars, which move in grooves located in a disc fastened to the shank of the die-holder. The cam disc is revolved by hand in accordance with suitable graduations, and its grooves cause the cutter bars to approach or recede from the central aperture. When thus adjusted, the screwed spindle before referred to is operated to bring one or other of the pawls into position to gear with the ratchet teeth on the die-holder, and cause it to rotate with the stock when the latter is used. Claims: The general arrangement and details of a pipe-threading device, substantially as described.—No. 7205. May 8th, 1890. 8*d*.

Digitized by Google

FRICTION CLUTCHES.—*J. Wild, Oldham.*—In this clutch an annular carrier is keyed to one of the two disconnected shafts which are in line with one another, and an internally faced pulley is keyed upon the end of the companion shaft. In the annular carrier any convenient number of shoes are fitted, which may be forced outward by screws or by inclined planes actuated by levers (which in turn are operated by the well-known arrangement of grooved sliding collar) so as to be forced into contact with the internal periphery of the pulley mentioned above. To compensate for the wear that may occur in the shoes and their connections, the operating screws turn in nuts separate from the main body of the annular carrier, and are secured in place therein by set screws or in any convenient manner. By loosing the set screws the nuts may be turned independently so as to force the shoes, together with the screws, further outward from the shaft, as wear takes place. Or the shoes may themselves constitute the nuts, and adjustment be made by removing the levers and giving the screws independent rotation before replacing the levers. Claims: The friction clutch as described, and the method of compensating for wear by methods similar to those above mentioned.—No. 7062. May 7th, 1890. 6*d*.

ELECTRICITY.

ELECTRICAL DISTRIBUTION.—*Siemens Bros. & Co., London. (Siemens & Halske, Berlin.)*—The aim of the inventors has been to design an arrangement for enabling secondary batteries to be employed for storing up electrical energy produced by alternate current machines. It is well known that alternate current machines can be made to act as motors, if there be imparted to them a speed of rotation which will produce an alternating current, the phase of which shall be synchronous with that of the alternate current of the generator, and it is also known that a rotary transformer can be readily produced which shall transform alternate currents into continuous currents by coupling an alternate current machine either directly or indirectly with a continuous current machine. If the alternate current machine be then supplied with alternating currents, it can act as motor driving the continuous current machine, which will then produce secondary continuous currents. Such combined machines, which can be mechanically combined to form a single apparatus, can also be employed in an inverted manner, for converting continuous currents into alternating currents. The present invention is

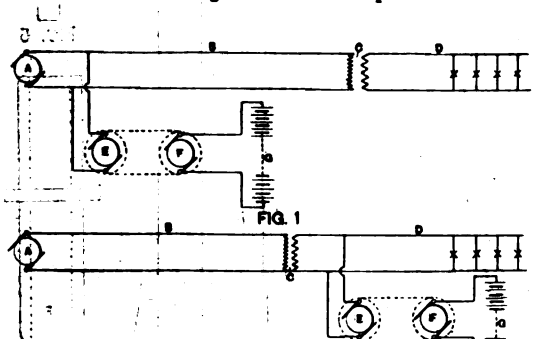

FIG. 1

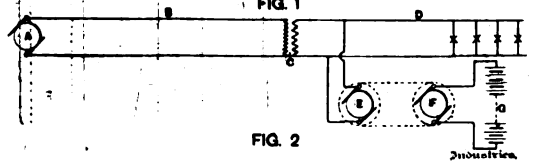

FIG. 2

based upon the above-described action. The continuous current from the secondary battery is not sent into the circuit, but is employed for working rotary transformers producing alternating currents, so that the network is supplied with alternating currents by means of the secondary batteries in the same manner as such currents are supplied from the central station. The accompanying illustration shows such an arrangement. In Fig. 1 the accumulator battery is arranged at the central station. A is the primary alternate current machine of the central station which supplies currents to the primary network D, from which the currents pass through the transformers C into the secondary network D. E is the secondary alternate current machine which is coupled with the continuous current machine F. The continuous current machine F supplies current to the accumulator batteries G if these are to be charged. If, on the other hand, the charged batteries are to supply the network, the continuous current from the batteries drives the machine F as motor. The latter then drives mechanically the alternate current machine E, from which alternating currents pass into the network, together with the currents proceeding from A, A and E being connected in parallel. Fig. 2 shows a similar arrangement, the only difference being that in this case the accumulator batteries, with their rotary transformer E F, are connected directly with the secondary circuit D instead of with the primary circuit B. The above-described mode of employing accumulator batteries on alternating current circuits has the advantage that the construction of the distributing network and its connections with the central station can be varied, because the storing stations are of precisely the same nature as the central station. It is also possible with this arrangement to supply the current partly from the accumulator batteries and simultaneously partly from the central station. With this mode of using rotary transformers it is immaterial whether the alternating current has before been transformed one or more times in ordinary alternate current transformers; the secondary batteries can therefore be arranged either in the central station itself or in proximity thereto or at a distance therefrom. Claims: The methods of distributing electrical energy substantially as described.—No. 9602. June 20th, 1890. 8*d*.

ELECTRIC METERS.—*M. Koechlin, Vevey, Switzerland.*—This is an electric meter based upon the principle of the Wheatstone bridge, shown diagramatically in Fig. 1, with lettering corresponding to that upon the sectional elevation and plan of the meter, Figs. 2 and 3 respectively, for in one loop of the circuit two solenoids A are inserted, which excite a soft iron core B, in whose field two other solenoids G are moveable. It results from this that if the equilibrium of the bridge be broken, the moveable solenoids are repelled or attracted, and by their movement displace a rheostat D, until equilibrium is again established. At the same time that this movement occurs, a roller E, moveable on a circular table F, turning under the action of clockwork, is moved correspondingly to a new position. The roller is mounted on an arbor G, to which it imparts rotation by a feather, and a groove, the arbor driving the wheels of the counter. The variable rheostat D is arranged in such a manner that for equal mechanical displacements it gives equal variations of resistance. To this end it is formed of three discs of vulcanised fibre mounted on a horizontal spindle; the middle disc, which is of a smaller diameter than the

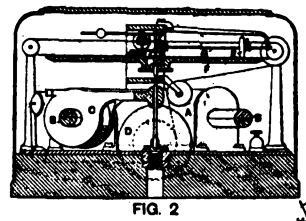

FIG. 2

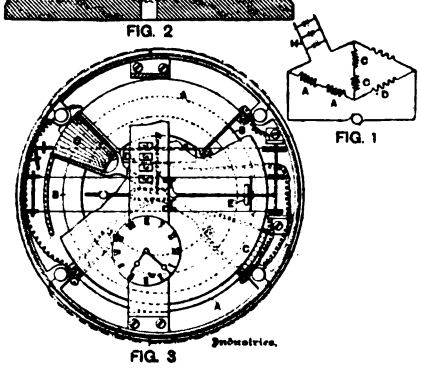

FIG. 1

FIG. 3

others, is formed with regular teeth, and also with a circular series of holes. Between the teeth and through the holes is wound helically a coil of iron wire, one end of which is insulated, whilst the other is in communication with a metallic pulley. The two outer discs of fibre are connected by a metallic ribbon, and a drop of mercury is imprisoned in the remaining annular space. It is obvious that on rotation of the discs, the drop of mercury remaining always at the lowest point, varies the interposed resistance, the rotation of the disc varying the length of wire between the mercury contact and the other terminal which moves with the disc. The movements of the sliding roller before mentioned are proportional to those of the rheostat D, and hence inversely proportional to the resistance of the lamps H. As the roller travels farther from or nearer to the centre of the table F, its speed of rotation increases or decreases in the same ratio. Claims: The automatic Wheatstone bridge arrangement, constituting an electric meter. The variable rheostat as described, and the various forms of integrating apparatus, in this connection, described in the specification.—No. 3740. March 2nd, 1891. 8*d*.

ELECTRICITY METERS.—*R. Kennedy, Glasgow.*—In this meter an ammeter or wattmeter is combined with two pendulums and a differential gear, which actuates an indicating mechanism. The lengths of the pendulums are variable, and are altered by the ammeter or wattmeter and the differential gearing operates the indicating mechanism in accordance with their difference of vibration, the pendulums being adjusted to vibrate synchronously when no electricity is passing into the meter. Fig. 1 is an elevation showing the pendulums, escapements, and meter coils, and Fig. 2 is an end elevation of the same. A and B are the two pendulums, both alike as to size and weight; C and D are the corresponding escapements, driven by separate springs and trains of wheels. E is a flexible strap passing over the pulley F mounted on the spindle G. The opposite ends of this strap are

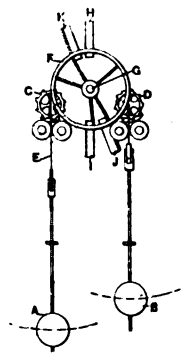

FIG. 1.

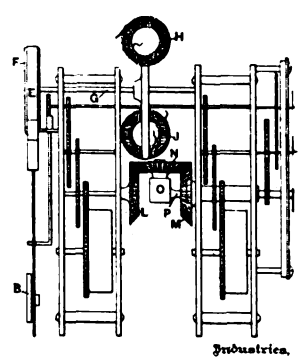

FIG. 2.

extended and carry the pendulums as shown. On the spindle G the meter movement is mounted, the meter being preferably of the class in which coils of wire carrying the current repel each other, and consisting of two fixed coils H I and two moveable coils J K mounted on the cross-arm of the pulley spindle. When current passes through the coils the moveable coils are repelled to a distance proportional to the electricity passing, and one pendulum is pulled up and shortened, the other being proportionately lengthened, the resulting difference in the speeds of the gear governed by the pendulums being recorded by the index worked by the differential gear. The differential gear is of a well-known type, the wheel L being driven by one train and M by the other, the third or floating wheel N being pivoted on O, which is mounted on a spindle P passing through the hollow spindle of M to the index train. The flexible strap E is guided by pulleys as shown. For use with alternating currents the moveable coils J K are replaced by two discs of copper. As an ammeter, a long solenoid may be used to act upon a core of iron wires which is pulled into the solenoid against the resistance of a spring, operating the pulley F accordingly. Claims: Measuring electricity by the difference between the rates of vibration of two pendulums, the difference being caused by the lengthening and shortening of the pendulums under the action of an ammeter or a wattmeter; the combination of the mechanism referred to in the foregoing parapraph, with differential and indicating gears.—No. 8867. March 4th, 1891. 6*d*.

CHEMISTRY.

MANUFACTURE OF GUNPOWDER.—*H. Kolf, Bonn, Germany.*—This invention relates to the manufacture of a nearly smokeless gunpowder which is especially free from danger by reason of the non-employment of picric acid, picrates, and chlorates, the use of which has hitherto rendered the manufacture and the manipulation of so-called smokeless gunpowder dangerous. This objection is removed by the use of carbon-hydrates, or products which possess the qualities of carbon-hydrates, in a nitrogenous condition. The materials containing carbon-hydrates are grain, malt, malt-flour, and waste from the mash, the roots, stems, and leaves of plants of the genus *althæa*, and waste of all kinds resulting from the manufacture of starch, and from breweries and distilleries. These materials are nitrated in the usual manner by treating them with nitric and sulphuric acids preferably at a temperature of between 20° to 30° C. in vessels or vats under a pressure of from 2 to 5 atmospheres. The nitrated mass, after having been drained and thoroughly washed in cold water to completely free it from acid, is dried in a temperature of about 40° to 50° C. and then crushed or ground; or the crushing or grinding can be effected while the material is in a semi-dry condition. For the purpose of ensuring regular combustion of the powder and to regulate the point of combustion, sulphur is introduced into the powdered nitrated mass. The sulphurising materials are caused to act on the nitrated powdered mass under a pressure of, say, about 5 atmospheres. In about two hours' time the nitrated and sulphurised mass is freed from the sulphurising substances by carefully washing it, and it is then treated with a suitable oxygen-yielding medium (after first drying it in a temperature of from 60° to 80° C.) by submitting it to the action of a solution containing about 5 to 20 per cent. of nitrate of potassium, sodium, or ammonium at an ordinary temperature for about 12 hours under a pressure of about 4 to 5 atmospheres, produced, preferably, by compressed air or hydraulic power. To separate any superabundant nitrate which has not been intimately absorbed by the mass, and would, therefore, act prejudicially to the consistency of the product, the latter is quickly rinsed or dipped in cold water and then dried in a temperature of about 80°. To bring the product into compact granular or prismatic form it is damped or soaked in a solution containing 2 per cent. of a binitro-combination of one of the before-named materials containing carbon-hydrates, or of cellulose, and is then formed by pressure into grains, cakes, or prisms as may be desired. It will be obvious that the solution used for the above-stated purpose may also be employed in a more or less concentrated form, and can be produced in the product obtained as before described, and which already contains nitrocarbon hydrates, by simply damping it with one of the known solvents for dissolving the nitrocarbon hydrate instead of a prepared solution. Claims: The manufacture of smokeless powder characterised by the use of nitrated carbon-hydrates or plants such as those herein-mentioned or their waste products, containing carbon-hydrates, which are sulphurised by treatment with a sulphide of hydrogen, sulpho-hydrates, or poly-sulphides under pressure; impregnated with oxygen-yielding mediums by treatment with a solution of the same under pressure; the product thus obtained is moulded by pressure with a binitro-carbon-hydrate or a binitro-combination, or with their solvents, such as acetic ether, acetone, or oil of camphor, into the desired form.—No. 8811. June 7th, 1890. 6*d*.

MISCELLANEOUS.

SPANNERS.—*Alfred Ladds, London.*—The spanner or wrench described below is self-adjusting to articles of various shapes and sizes, and is capable of being stowed into a small compass. The main jaw of the wrench is made separate from the power handle or lever, but is connected thereto by a pin (on which it is capable of turning) passed through one of a series of holes provided in the lever and provided also in the end of the jaw. Linked or hinged to the free end of the main jaw is a pressure jaw, and on the back of this latter the lever is caused to bear when the wrench is gripping an article; therefore the greater the power applied to the lever, the greater will be the pressure of the end of that lever upon the pressure jaw, and the more firmly will any article placed between the jaws be held. The faces of the jaws may be plain, but it is preferred that they should be serrated. To enable the wrench to operate in confined spaces which would not admit of the insertion of the jaws to engage the whole depth of the article, a recess or recesses is or are formed in the lower face of the jaw, tapering towards the outer edge for the reception of the nut. To render open spanners of the ordinary construction more durable, the outer ends of their jaws may be connected by a bridge piece forged in one with the jaws in the process of manufacture, or afterwards applied as may be convenient. This bridge piece is notched to allow of the passage of the screw on to which a nut may be screwed by the spanner in question. Claims: A wrench or spanner having two jaws which are hinged together and to the lever or handle of the spanner, which has its bearing or fulcrum on one of the jaws and exerts pressure upon the other; the modifications of this type of spanner shown; the improvement of ordinary spanners by the bridge piece as described.—No. 19745. December 4th, 1890. 6*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

AN IMPROVED TUBE BENDING MACHINE.

The accompanying illustrations, Figs. 1, 2, and 3, represent a general view, a plan, and a part elevation respectively of a useful machine recently patented by Mr. John Laidlaw, and which is being introduced by the firm of Messrs. Watson, Laidlaw, & Co., engineers, Glasgow, for bending tubes without the necessity of filling them with some yielding material to preserve an accurate section. As we recently referred to this machine as a novel patent under our "Abstracts of British Patent Specifications" (see *Industries*, Vol. X., page 456), a brief description is all that will be required. To begin, then, we may explain that the peripheries of the semi-circularly grooved rollers A A are kept in contact—attention being given to the fact that the bending of a tube tends to distort its cross-section to an oval, the widest portion being at right angles to the plane in which the tube is bent—by making the grooves in the rollers A, D, and E to exactly fit the cross-section of the originally straight circular tube, and thus prevent "ovalling." There is consequently a pressure set up against the tube by the rollers, and the rotation of the latter draws the tube along, all the rollers being driven at a uniform speed by suitable gearing. B is the machine frame, carrying a slide C, on which are mounted, in fixed centres, the two rollers A A. The other pair of rollers D and E rotate upon centres secured to the frame, and are driven by any convenient means, such as the gearing shown. The roller E is geared to one of the rollers A by spur wheels K L M, which are maintained constantly in gear by a linked frame shown in the plan, and a screw N operated by the hand-wheel O serves to adjust the frame carrying the rollers A relatively to the rollers D and E, for varying the curvature of the tube.

AMERICAN IRON AND STEEL PRODUCTION IN 1890.

Sir James Kitson's recent address before the Iron and Steel Institute, to which we referred in our issue of the 15th ult., directed attention to the great increase in production of iron and steel in the United States during the past few years. The Report of the American Iron and Steel Association for last year has recently been published, and a few additional facts and figures may be noted. The Report states that for the first time in the history of America the production of iron has exceeded that of Great Britain, and that it not only surpassed British production for the year 1890 by about 1,200,000 tons, but exceeded by 600,000 tons the greatest production ever realised in Great Britain in any year. During the year 1890 the most striking fact in the history of the trade was that, notwithstanding an enormous increase in consumption of iron, the market prices, both of pig iron and of the more important products of iron and steel, steadily declined during the entire year, a fact which, the Report remarks, is quite contrary to the usual experience of ironmasters, who are apt to find that when there is a largely expanding consumption, so that a marked increase in production becomes possible, there is usually an advance in prices, or prices are maintained at something above the ordinary level. But in the year 1890 expansion in several directions took place at once. There was enormous enlargement of consumption, the total amount of pig iron used being 8,959,679 tons, which is more than twice the consumption in 1885, only five years earlier. The following figures, comparing the consumption of pig iron for the years 1875, 1880, 1885, and 1890, record a progress such as no other country has witnessed in the consumption of any of the great products of industry:—

	Consumption.		Production.
1875	2,000,000 tons.	...	2,023,733 tons.
1880	3,990,415 „	...	3,835,191 „
1885	4,348,844 „	...	4,044,526 „
1890	8,959,679 „	...	9,202,703 „

The extraordinary increase in consumption, amounting to about 1,200,000 gross tons for the year, was surpassed in 1890 by the increase in production of pig iron, which was 1,599,061 tons larger than that of 1889, an increase of 21 per cent. for that year, as the production of 1889 had been greater than that of 1888. But the cheapening of production was even more remarkable than the increase, and it is found that the new establishments put into operation appear to be able to produce pig iron at a lower average cost than establishments in any other part of the country. In this connection a few figures may be quoted from another report which the Hon. Carroll D. Wright, National Commissioner of Labour, recently transmitted to Congress through the President,

AN IMPROVED TUBE BENDING MACHINE.

and which is the result of several years of careful investigation in the United States and Europe, based upon an examination of the books of leading manufacturers and expert special agents of the National Department of Labour. The entire report is most exhaustive, making a volume of 1,200 pages, and one of its most striking features is the great advantage possessed by the Southern States as regards the cost of materials.

The following table shows the comparative cost, in dollars, of making pig iron in different establishments in the United States and Europe, the latter meaning Germany and Belgium. Each line represents the work of a separate establishment, and, of the 118 given in the report, the following fairly represent the highest, lowest, and average cost of materials, labour, and total cost per unit in each locality:—

THE COST OF MANUFACTURING PIG IRON.

Locality.	Cost of Material.	Labour.	Total Cost.
Northern	$17·728	$3·589	$23·165
Northern	13·223	1·194	15·202
Southern	7·757	1·461	10·279
Northern	11·991	·975	13·584
Northern	11·663	1·364	13·433
Europe	9·559	·418	10·394
Europe	12·228	·912	13·434
Great Britain.....	9·230	·601	10·290

Europe	7·182	·950	8·132

The statistics of the Iron and Steel Association show that the increase in Southern production was not quite so great as it had been from 1888 to 1889, and being produced at a cheaper rate, it had the effect of steadily depressing the price during the year. The Report directs attention to the great increase in the consumption of Bessemer steel in other forms than in rails. Although the use of rails in the year 1890 was considerably larger than in the previous year, and the production 23 per cent. greater than in 1889, nevertheless the most striking feature in the year's history was the enormous demand for steel in structural and other forms. It was a year of almost unprecedented building, and it is probable that the demand for steel in other uses than in connection with railroads was greater than it will be again for some time to come.

THE BALANCING OF CENTRIFUGAL PUMPS.*

(*Concluded from page* 508.)

I NOW come to the main subject of "Balancing Centrifugal Pumps." Among the phenomena that arise in working these pumps is unbalanced pressure. We generally find, after making an unbalanced pump, that it "burns out" its bearings. This is sure to be the case if it is not supplied with the necessary balancing arrangement; the shaft and bearings are soon destroyed, because the pressure exceeds the limit allowed for bearing areas.

I am referring now to a disc like the one in Fig. 5. But before I speak of this pump, I will mention in connection with Fig. 4 that this encased runner or wheel, an invention of Mr. Andrews, was one of the things that James Stuart Gwynne took to England and introduced in his first pumps, and continued to manufacture for several years, but subsequently abandoned. Neither he nor his brothers John and Henry Gwynne have made encased runners for twenty years past, using only open wheels. Fig. 4 is a vertical section through a pit pump, as it is called in California, from designs of mine made four years ago. The water enters by double inlets G at the top of the pump, and then through the nozzle H to the interior of the wheel I, and is discharged by the periphery J into the casing L, against a pressure due to the head. The heads are from 50ft. to 90ft., and if, in this case, we assume 60ft., then the pressure at J, J, and also in the spaces D and E, above and below the wheel, is 60 × ·43 = 25·8lb. per inch static, or about 30lb. working pressure per inch of area. Suppose the wheel I to be 30in. diameter, then the area 706·8 times 30 (lbs. pressure) gives 21,204lb., or more than 10 tons of pressure on each side. Following this matter of internal pressure further, suppose the casing J to be 40in. diameter, then the pressure on the top and bottom plates will be about 18 tons. This seems enormous, and it is also in a sense anomalous, because if the wheel I is changed to the form shown in Fig. 6, there is no lateral thrust on it at all, and the pressure on the casing J is nothing, or negative at the centre, and the whole less than one-half that before estimated.

Now, as to balancing, we will return to the wheel I, Fig. 4. It has been explained how this wheel sustains on its sides a pressure of 21,204lb., working under a head of 60ft. and a speed of 10 $\sqrt{60}$ = 77·4ft. per second, but the whole area of the sides is not exposed. The inlet F must be deducted from the top side. The diameter of the inlet nozzle H is commonly made one-third that of the wheel, and in this case 10in., so that this area, 78·5 square inches, must be deducted from the top side, and represents an upthrust of about 1 ton on the wheel. This is enough to sustain the wheel, and a shaft 2¼in. diameter, 60ft. long, with its couplings, pulleys, &c., and now we come to that point which suggested the discourse of this evening—the control of this thrust

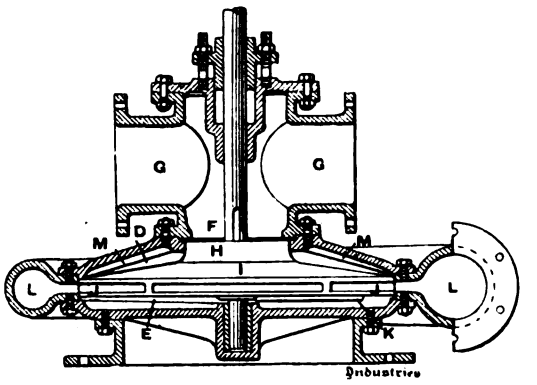

FIG. 4.

so as to balance such pumps at different heads when they have the same area of inlet at F. It must be remembered that in the quantities given I have assumed that no rotation of the water and no centrifugal effect takes place in the spaces E and D. This is the case when the runner or wheel is turned true and smooth as it should be, and fixed baffling vanes M are employed on the outer casing. It is evident that if rotation is set up in the spaces E and D, then whatever centrifugal force results is that much toward balancing the pressure in J; hence the amount of upthrust due to the inlet at F can be regulated by the amount of water rotation under the wheel at E; and this is the method I have adopted in these pumps, applying shallow vanes K on the bottom of the wheel of varied length and depth to suit the heads under which the pumps are to operate.

This is a very sensitive kind of balance. In one case, in the Santa Clara Valley, 1in. cut from the tips of the vanes K, which were only ⅛in. square, made a difference of more than 300lb. in the thrust upon the shaft. If the space E is much widened by the raising of the wheel, then the effect of the vanes K is less, and the upthrust is cumulative, increasing as the wheel rises. This feature has been discovered during six months past in practice, and was not foreseen in my original plans.

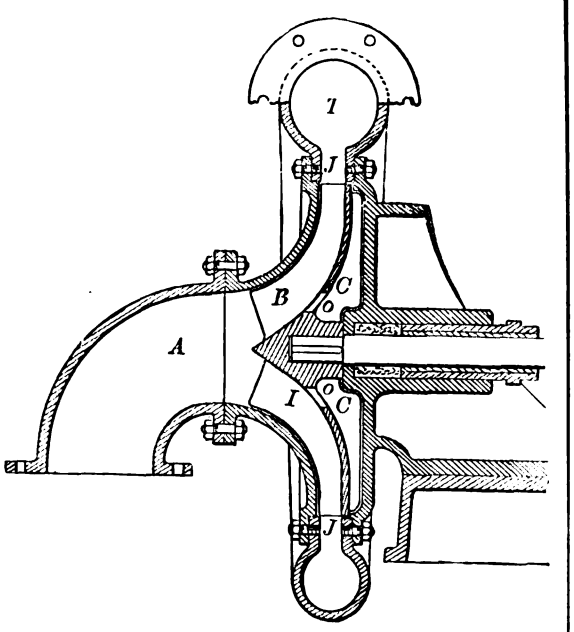

FIG. 5.

One other feature I must point out here. In all pumps with encased wheels, there must or should be maintained a water-tight joint around the nipple H. Any water forced back around this nipple will re-enter at the inlet F, and merely circulate in the pump. This is an objection to encased wheels, one hard to obviate, and should prevent them being used for pumping water containing grit or sand. Referring next to Fig. 5, the pump shown is the result of six years' fairly constant experience, as well as observation in this and other countries, and I think it will be a pardonable claim if I assume it to be one of the nearest approximations to the theoretical practice that has been made up to this time. The inlet A is at the side, so as to be accessible and easy to remove. The main casing T is volute in form, and so constructed as to be set in any position on the frame. The course of the water from A, through B to J, is by easy curves, and the area of sections is kept as nearly uniform as possible. The packing around the spindle is placed inside the main bearing, and there is, by reason of the concave form, but little overhang of the wheel.

Now as to balancing. The wheel, as may be seen, is a disc with vanes B and I on its front side. This disc, if 30in. diameter, made solid, and without vanes C on its back, would, under a head of 40ft., be subject to a lateral thrust as follows:—Area of wheel, 706·8in.; speed in feet per second, 10 $\sqrt{H}$; pressure per inch 19lb. = 13,429lb.

This is impracticable, hence the wheel is balanced in the following manner:—On its front are deep vanes I and B, and on the back are shallow vanes C. Now it is evident that centrifugal action is the same, or nearly the same, on each side of the wheel, but all the water passes on the front of the wheel. The rear or balancing vanes C are not quite as long as the main ones I. There is a difference of ⅜in. to ½in. at the tips, as seen in the illustration. This slight difference causes the centrifugal force on the front to overbalance that on the rear of the disc, causing a slow circulation of water over the periphery and through the holes O from the back to the front, just the reverse of what one would suppose. Now I maintain that a pump thus balanced is as nearly in equilibrium as one with a forked or double inlet, and is more likely to remain balanced, because there is less danger of obstruction, and, as can be seen, the waterways are more direct and easy. Thus it will be seen the working conditions of a pump are wholly changed by the kind of wheel employed. If the wheel is encased the whole interior of the pump sustains the discharge pressure. With an open wheel there is no pressure at the centre, and only one-half as much on the sides of the casing.

The friction is the same in both cases. With the enclosed wheels the friction is between the wheel and the water. With an open wheel, the friction is between the water and the main casing at the sides. Except in cases like Fig. 4, where thrust is desirable, I am inclined to think that open wheels, or wheels with vanes on each side of the central disc, are preferable. Fig. 6 shows an open wheel for a dredging pump, such as I have employed in a pump recently designed for the San Francisco Bridge Company of this city, and, also with a slight modification, for a pump to be used in the harbour at Boston, Mass. These wheels are made of steel and with five vanes, so as to admit stones or lumps of clay between them. There is no chance of obstruction, and in dredging there is no disintegration of the material beyond

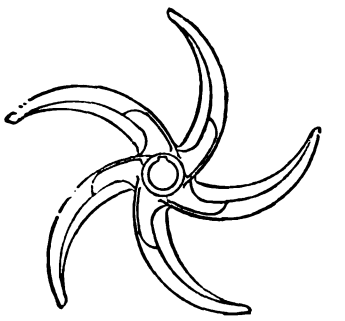

FIG. 6.

reducing it to the size of the discharge pipes. I have recently seen one of these pumps carrying more than 50 per cent. of solid matter.

Dredging pumps are commonly made with encased wheels to prevent the vanes from breaking, but this class of pumps—more than any other—requires open wheels. In 1885 I constructed in this city an open-wheel, single-suction pump that ran for months without choking or accident. Dredging pumps are also made with a double or forked suction, under the impression that this is required for balancing the wheel. This, as I have shown, is not necessary, and it need hardly be said that the tortuous passages and reduced section of the pipes is extremely objectionable, causing frequent stoppages and accidents to pumps of this kind. The wheel shown in Fig. 6 is strong enough to withstand blows from stones or pieces of iron that may enter the pump, and, moreover, is more efficient and requires less power than an encased wheel. The lateral thrust on a wheel of this kind is equal to the area of its shaft multiplied into the suction pressure, or about 80lb., just enough to keep the wheel in alignment if its bearings should wear.

In conclusion, I will say that centrifugal pumps have recently received a good deal of attention, and I think we are on the eve of having measurably fixed proportions for them. The size of the wheels for centrifugal pumps can probably never be made to correspond with the demands of theory, because the practical limit of speed for wheels is what the shafts and bearings will endure. I have read all the literature I could find on the subject of proportions for the centrifugal pump, but I find no intelligent answer to the problem of the size of wheels except that of Mr. Wagoner—namely, that they should be so proportioned that the motor will make one complete revolution only. So far is this from practice, however, that there are pumps being made that move the water through 1,500° before its discharge. The limit of speed in these pumps is, as before said, to be found in their bearings. The size of the apertures are determined by the obstructions that may have to pass through with the water; the thickness of the casing, and various other features, may be determined theoretically, based on the strains in most cases. What we will have in the end, probably, will be a compromise between the theoretical, commercial, and operating conditions, and we shall then settle down to something like uniform practice.

On the Pacific coast I think we have done more to develop centrifugal pumps than all the rest of the United States put together; in fact, it has largely been done here during eight years past. The pumps that are being made in the East are constructed in many respects on lines taken from practice on this coast.

* Abstract of a paper read by Mr. J. Richards, of San Francisco, before the Technical Society of the Pacific Coast.

THE "DEMON" WATER MOTOR.

The accompanying illustrations, Figs. 1, 2, and 3, represent a general view, a sectional elevation, and an end view, partly in section, of the above motor, made by Mr. P. Pitman, of Aubrey Road, Withington, Manchester. This motor should be found very useful for housekeepers and shopkeepers' purposes, and various other requirements where the introduction of steam or gas would not

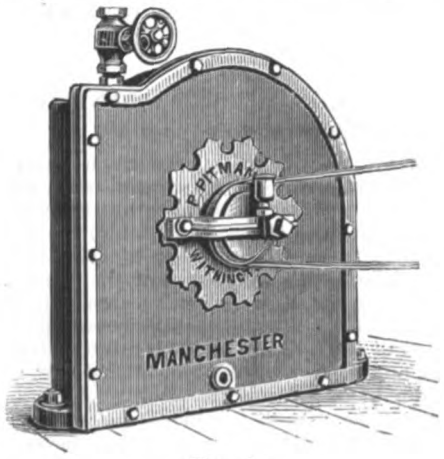

Fig. 1.

be desirable. The construction of the motor is exceedingly simple. Mounted on a horizontal shaft B which runs in adjustable bearings (shown in large size, Fig. 5) is a disc A. On the faces of this disc and near its periphery are mounted alternately small cups or buckets C, against which water under pressure and from any suitable source is discharged through twin jets or nozzles D (also shown in large size in Fig. 4), thereby causing the said disc to rotate. The water thus taken up by each

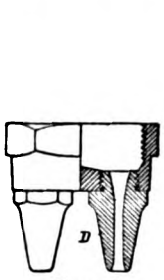

Fig. 4.

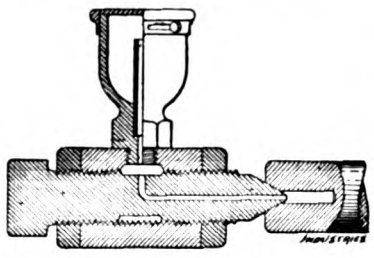

Fig. 5.

cup is carried down to the lowest position of the latter, and is then deposited and allowed to escape through the exhaust port E. The machine, it will thus be seen, can be driven at at a uniform velocity, there are no pistons or complicated parts to get out of order, and as there is no dead centre it can start in any position. The shaft and all wearing surfaces are made of the best material, and a removable cover is provided for allowing easy access to the interior. The motor is made in various sizes from ¼ up to 2 man-power.

ON TESTS FOR STEEL USED IN THE MANUFACTURE OF ARTILLERY.*

The physical and mechanical properties of steel depend upon so many conditions, that the greatest difficulty exists in devising tests which shall give the user of steel reasonable certainty as to the intrinsic qualities of his material, as well as some idea of its condition with reference to internal stresses. At first sight it would appear that chemical analysis ought to provide the most certain indication of the nature of a specimen. The purchase and manufacture of very many substances are guided by chemical tests alone, and the results are eminently satisfactory. Why should not chemistry, in its present advanced state, render equally certain indications as to the qualities of steel? The answer, I think, lies in the circumstance that the mechanical properties of steel, and of alloys generally, are affected in a remarkable manner by extremely minute quantities of substances associated with the dominant metal, by the relative proportions of these substances, by the changes in some, or in all, of them, produced by more or less rapid changes of temperature, which influence dissociation and reveal their effects by the singular phenomenon known as recalescence, which also indicates, though to a less degree, allotropic changes in some or all of the components. Chemical analysis sufficiently minute to detect even traces of every substance associated with iron, would be so tedious and costly as to be impracticable, and I fear that many years must pass away before chemical and physical science together will succeed in determining the laws which govern the mechanical properties of alloys. Some advance has already been made by Professor Roberts-Austen, who has shown that there

* Paper read before the Iron and Steel Institute on the 6th ult., by Dr. W. Anderson, M.Inst.C.E.

THE "DEMON" WATER MOTOR.

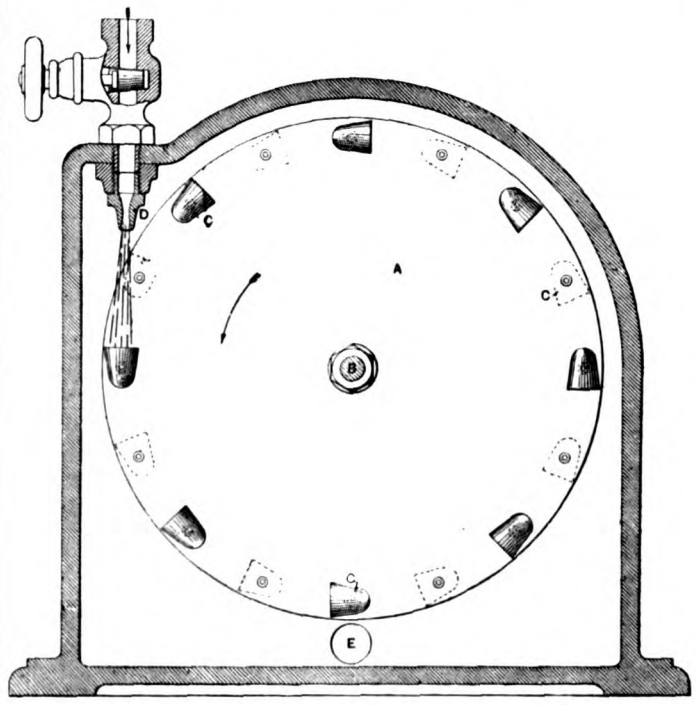

Fig. 2

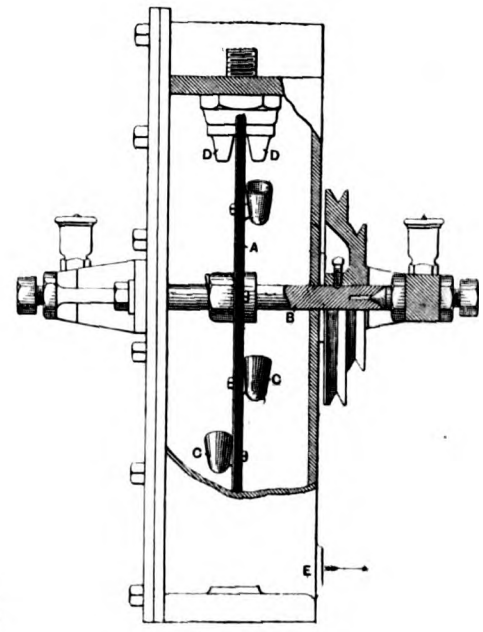

Fig. 3.

exists a relation between the mechanical properties of some alloys and of the atomic volumes of the substances of which they are composed, and I do not doubt but that farther investigations in this direction will enable metallurgists to predict with some certainty the effects of ingredients upon the mechanical properties of the substances to which they are added, but it is only those who have attempted such systematic work as Professor Roberts-Austen is now doing for the Alloys Research Committee of the Institution of Mechanical Engineers who can have any idea of the difficulties which surround the inquiry, chiefly arising from the practical impossibility of obtaining pure materials in sufficient quantity, owing to the liability to oxidation of the metals which are most used in the arts, to the disturbance caused by the occlusion of gases, and to other causes. The time which must necessarily elapse before a sufficient number of facts can be established to enable unassailable laws to be laid down, and the corresponding expense, are sufficient to deter the most enthusiastic investigator. But assuming, even, that the laws are discovered, and that the effect of each constituent of steel can be foretold, there will still remain the necessity of determining by analysis the exact constituents of the sample, which will involve expense and loss of time that cannot be conceded.

For these reasons, and acting under the advice of the President, the specifications of gun-steel used in Her Majesty's service exclude all definitions of chemical composition, in so far, at any rate, as the proportions of the ordinary ingredients of steel, such as carbon, manganese, silicon, phosphorus, and sulphur, are concerned. The introduction of new materials, such as chromium, aluminium, or nickel, is, indeed, not forbidden, but special care is taken to ascertain their effects upon the mechanical properties of the metal before their use is sanctioned. With respect to steel for lighter work, such as small arms, and especially for use in the production of swords and bayonets, some restrictions in chemical composition are imposed. In the former case, however, the percentage of carbon is defined with a view to the hardening which some portions of the components of a rifle have to undergo, and with reference to the durability of the barrels in regard to erosion by powder gases and abrasion by the bullets. In the case of swords, the difficulties of framing a satisfactory specification are so great, that the subject was specially referred to Sir Frederick Bramwell and to Sir Benjamin Baker, and by them the nature of the steel to be used was, indeed, defined by its chemical composition, but with the sole view to secure uniformity in supply, the sword maker being permitted to vary the components of the steel he proposed to use within certain limits. Once, however, the quality supplied is found suitable by the mechanical tests imposed, the chemical composition so selected is not to be departed from beyond reasonable limits of toleration, and I think that I may venture to affirm that the chemical tests for sword-steel were adopted only because it was found impossible to define the qualities required by physical tests alone, seeing that sword-blades have to be hardened and tempered, and are therefore subject to internal stresses, the nature and intensity of which certainly depend upon the chemical constituents of the steel, as well as upon the form of the blade and the mode of treatment.

It is not, I think, sufficiently realised that metals, and, indeed, most substances, are incapable of appreciable cubical compression, that is, change of volume under any stress that can in practice be brought to bear on them, under whatever conditions they may be, whether fluid, in the pasty state, at forging temperature, or cold. Like ice and water, steel and cast iron have a greater volume in the solid than in the liquid state, and therefore red-hot solid cast iron or steel floats on the surface of the molten mass, and hence, to some extent, is due the sharpness with which the metal takes the form of the mould in casting. The molecular motion in the metal, which results from the continued application of heat, culminating in producing a change from the solid to the fluid state, although it must constantly increase in energy, does not necessarily imply a greater mean distance between the molecules; in fact, the distance often becomes less, since the liquid is often more dense than the solid. Hence it is probable that the motion of the atoms in the molecule are affected, which view certain other changes due to thermal influence seem to support.

In the process of solidification the outer surface sets first and becomes rigid, but as the cooling proceeds, in spite of the slight swelling of the mass due to solidification, the loss of volume arising from cooling asserts itself, and since the outside cannot be drawn in altogether, on account of its being set and conparatively cold, the inside of the mass is broken up into porous places or into hollows, so familiar in large castings of unequal thickness; and even if solution of continuity does not occur, the casting is in a condition of internal stress, which a trifle may develop into rupture. As the cooling proceeds, the inside contracts, and the outside, which had set in a stretched state, becomes violently compressed, while the inside remains in a state of tension; and if the material yields, the sudden release of the outside surface causes the parts to spring asunder with such violence that the stress, which was originally compressive, is suddenly turned into tension high enough to cause rupture with such energy as to be generally accompanied by a report.

In the case of wrought steel cooling suddenly from forging heat, similar action takes place. When annealed from below the temperature *b* of Chernoff—that is to say, below the temperature from which, in cooling gradually, crystallisation can take place, the fall of temperature on the outside and in the inside proceeds at nearly the same rate, and the contraction is consequently uniform throughout, and no internal stresses arise; but if heated to the same point and quickly immersed in oil or water, the surface is rendered rigid in every direction, and contracts upon the heated core, and this being incompressible, the surface has no alternative but to stretch. If it does this without fracture, the mass of metal is apparently uninjured, but should the tenacity be unequal to the stress, rupture takes place at once. Should the metal survive the violence it has been subjected to, the subsequent cooling will gradually relieve the tensile stress on the surface, and substitute a compressive one in all directions, while the core will be in a state of tension also in all directions, and in some cases these stresses become so severe that a slight disturbance of temperature, or the application of mechanical force, will determine rupture with more or less noise. This has been frequently observed in hardened armour-piercing shot, in steel coining and stamping dies, and even in oil-treated gun hoops and tubes, though made of mild and tough steel; and in these the late General Kalakoutsky succeeded in accurately measuring the strains in a great number of instances, and in calculating the intensity and direction of the stresses which produced them. In consequence of the conjugate nature of the stresses, the fractures are generally of a serrated, branching, and diagonal character. As there is no such thing as an absolute elastic limit time, to some extent, obliterates the internal stresses; the metal slowly yields under them till a sort of armed neutrality is produced, so that after a few months' repose spontaneous fracture need hardly be dreaded; and for this reason dies and armour-piercing shot are kept in store for some time before being issued for service. The proper way, however, to restore neutrality, when hardness need not be retained, is to heat the steel to about the temperature *a* of Chernoff's scale (about 900° Fahr.), and suffer it to cool slowly. This is found to obliterate the internal stresses, while retaining, in a great measure, the so-called high elastic limit and ultimate strength which oil-hardening undoubtedly communicates. If, however, the process of hardening has set up fissures or cracks, however minute, in the interior of the mass, and these are just as likely to be longitudinal as transverse, no subsequent annealing can repair the mischief done, and in this lies the great danger of oil-hardening. I attribute to it most of the failures which have occurred in artillery; and although all nations are in accord in practising the oil treatment of gun-steel, it is a remarkable fact that civil engineers do not feel justified in taking advantage of the undoubted increase of elastic and ultimate resistance communicated to steel by the process, on account, I presume, of the risks attending it.

THE NICARAGUA CANAL.

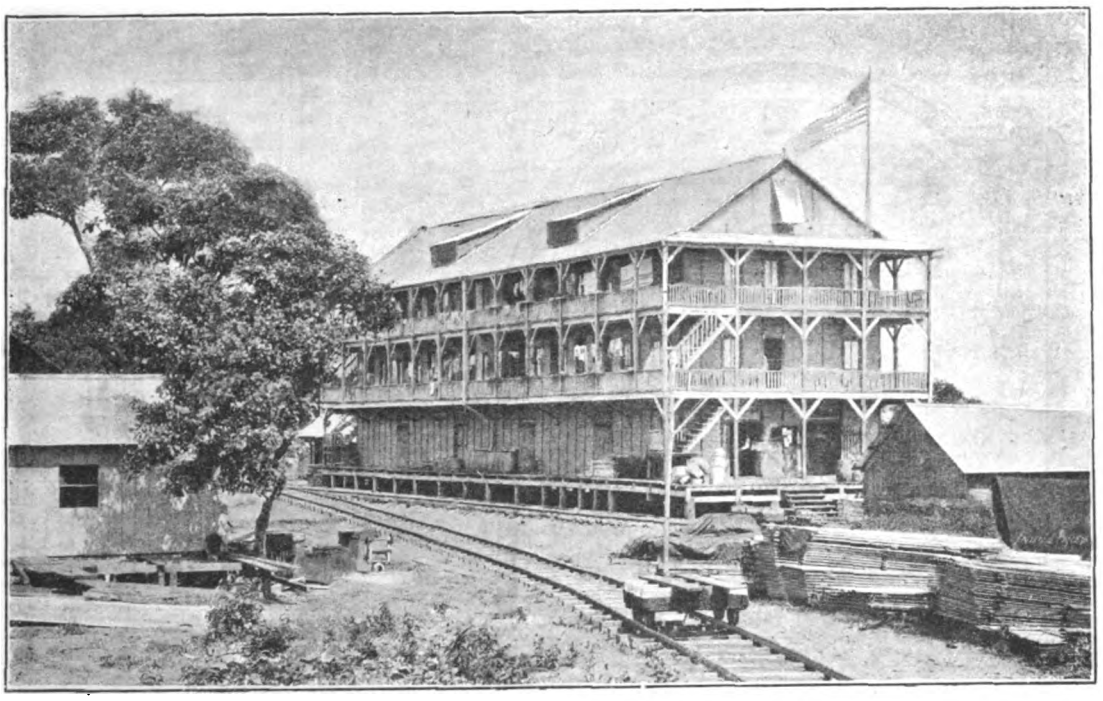

Fig. 9.—Storehouse and Staff Quarters at La Fé.

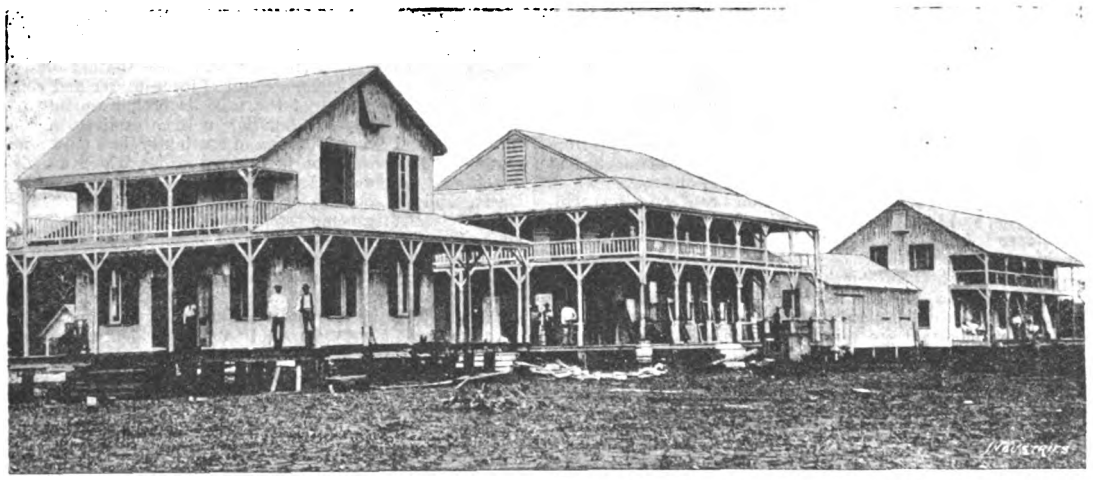

Fig. 10.—Hospital Buildings Looking West.

THE TIN DEPOSITS OF SOUTH DAKOTA.

A recent Consular report states thav the greatest interest is taken in the tin deposits in South Dakota, U.S.A., with regard to which many conflicting reports have been circulated, and a definite opinion as to the commercial value of the tin found can scarcely be formed from the work that has been done. Professor Carpenter has made a second survey of the district. Professor Vincent and many American and English experts have visited the mines and written most favourable accounts of the richness of the deposits, which are said to be inexhaustible, and Mr. Samuel Scott, mining engineer, recently furnished an able report from personal observation. The Glendale Mill, owned by the Tin Mining Company of Chicago, is the first which has placed American tin on the market: it is the only mill which has yet cast any tin ore pigs, and is said to be working steadily on a small scale, capable of working only 30 tons a day, but a larger plant is being erected, and the statements of Mr. Richards with regard to the richness of the ore are said to be confirmed. The expense of mining and treating one short ton of ore is as follows:—Mining, 4s. 2d.; concentrating, 2s. 1d.; smelting, 1s. 7d.; and incidental expenses, 1s. 1½d.; total, 8s. 11½d., which compares favourably with the cost in Cornwall, while the mines are considered a great deal richer. The work is done at present in a simple manner, by crushing and re-crushing the ore, and passing it successively through sieves till the required fineness is attained, a fine vanner being used to separate the ore and concentration effected by gravity methods. The smelting is done in a reverboratory or cupola furnace, and the molten metal is then cast into pigs.

Though tin deposits were discovered in the Black Hills some eight years ago, the excitement at once created by the discovery in a measure abated till the McKinley Act renewed the interest taken in the subject. At first no one in South Dakota knew much about tin, and some of the first capitalists who bought up claims appear, possibly for their own interests, to have discouraged the idea that mining could be successfully carried on, as it would be found impossible to dress the ore. Samples, however, of acknowledged richness were sent to New York, and mining on a small scale was commenced; but the first mills were soon stopped, and reports circulated that they could not be worked so as to be of commercial value. The Etta Mine at that time bought up a great many claims, and after about three years this enterprise was consolidated into the Harvey Peak Tin Mining, Smelting, and Manufacturing Company, of New York and London, a great part of the capital being invested by English capitalists. This is the largest enterprise in the district, and owns over 400 claims, which are being carefully prospected. There are between 300 and 400 men now employed, and about 500,000 tons of ore are in sight, with, it is stated, an assay of 14 per cent., while selected specimens, it is affirmed, have shown as much as from 30 to 40 per cent. A large concentrating plant and smelting furnaces are being erected by this company, which will probably be ready for working during this summer. There are also in the district nine other companies, variouly distributed, engaged in similar operations.

The chief deposits of tin are found in Custer and Tennington Counties, where there are about 7,000 locations. The veins vary in width from 1ft. to more than 300ft., the length from a few yards to five miles, and the outcrop ranges from a few feet to more than 150ft. above the surface. It is said that at least 4 per cent. of tin can generally be depended on. Numerous other minerals are found with the tin, but at present attention is almost exclusively drawn to the tin ore. The necessary fuel for working the mines is found in abundance in the immediate vicinity; inexhaustible resources of bituminous coal exist on the outskirts of the Black Hills, and the vast petroleum fields of Wyoming are at no great distance.

THE NICARAGUA CANAL.

V.

ESTIMATED COST AND QUANTITIES.

(*Continued from page* 482.)

Considering the wide divergence which bitter experience has generally proved to exist between the estimated and actual cost of large engineering enterprises, the company undertaking the construction of the Nicaragua Canal have very wisely refrained from tying themselves down to a definite sum as the cost of the work. According to Mr. Menocal, it is, however, calculated that the total cost will not exceed $90,000,000—say, £18,000,000—exclusive of banking commissions, interest during construction, and other expenses not included in the engineer's estimate. It is, unfortunately, just these "other expenses," as the case of the Panama Canal has shown, that run up the little bill to an extent never contemplated by the confiding shareholder. It must be admitted, however, that the surveys and preliminary studies appear to have been very detailed and thorough in their character, and in so far preclude any probability of a gross error in the purely engineering estimates. Of the material to be removed, 7,000,230 cubic yards of rock will have to be excavated from the Eastern Divide, and the cost of this work is estimated at 22 per cent. of that of the whole canal. From the Western Divide the removal of 5,696,507 cubic yards of rock will be necessary. The conditions under which this task will be carried out are favourable, as has already been pointed out with respect to the Eastern Divide, while for the cutting through the Western Divide it is stated that ample facilities exist for the deposit of the waste material not used in the construction of breakwaters, locks, dams, &c. More than twelve miles of the 26·789 miles of canal in excavation will be formed by dredging at the sea level. The healthiness of the climate in the territory to be traversed by the canal is an advantage that can hardly be overrated. In the only portion, that between Ochoa and Greytown, in which trouble from climatic causes might have been expected, the health of the employés of the company, during more than two years of hardship and exposure, has been excellent. West of Lake Nicaragua the climate is as healthy as any in Central America.

It is interesting and instructive to compare the estimated cost of the Nicaragua Canal with what has actually been spent on the Panama Canal enterprise. When the suspension of payments took place in 1888, according to the report of M. Monchicourt, the official liquidator, 783 millions of francs, or, say, £31,320,000, had been spent on the actual construction, and no less than 390 million francs, or £15,600,000, in Paris, this latter sum being required for what may be broadly termed "financing" the undertaking, and including an item of 20,432,554fr., or, say, £817,302, by way of "douceur" to the French Press. In the report of M. Lucien Bonaparte-Wyse, to which we drew attention in a recent number of our journal (see *Industries*, Vol. X., page 422), the capital necessary to complete the Panama Canal is set down at £24,000,000. If we add this to the sum already spent on construction—leaving other items out of account—we reach the grand total of £55,320,000.

In the Report of the United States Interoceanic Canal Commission, issued in 1876, the Panama route was also considered among others, and its cost estimated as being nearly 50 per cent. greater than that of the Nicaragua route. The actual words of the report were as follows:—"At the request of the Commission, for reasons previously stated, the Hon. Secretary of the Navy caused a careful instrumental survey of this route to be made in the vicinity of the line of the Panama Railroad. The proposed route is 41·7 miles long; has a summit level of 123·7ft. (surface of canal above the ocean); requires a dam and feeder 10·5 miles long; a retained dam at Obispo Station; an aqueduct across the Chagres River; a deep cut at the summit level 4·81 miles long, with a mean depth of 102ft. and greatest depth of 197ft.; the construction of the lift-locks necessary to overcome the summit level, and—what is common to all of the routes—the construction of harbours on each coast. The deep cut would probably be subject to land slides, from which the Panama Railroad has suffered seriously, and the canal would be exposed to serious injury from floods. The excavation of the deep cut, involving the handling and transport of millions of cubic yards of materials, is,

Digitized by Google

THE NICARAGUA CANAL.

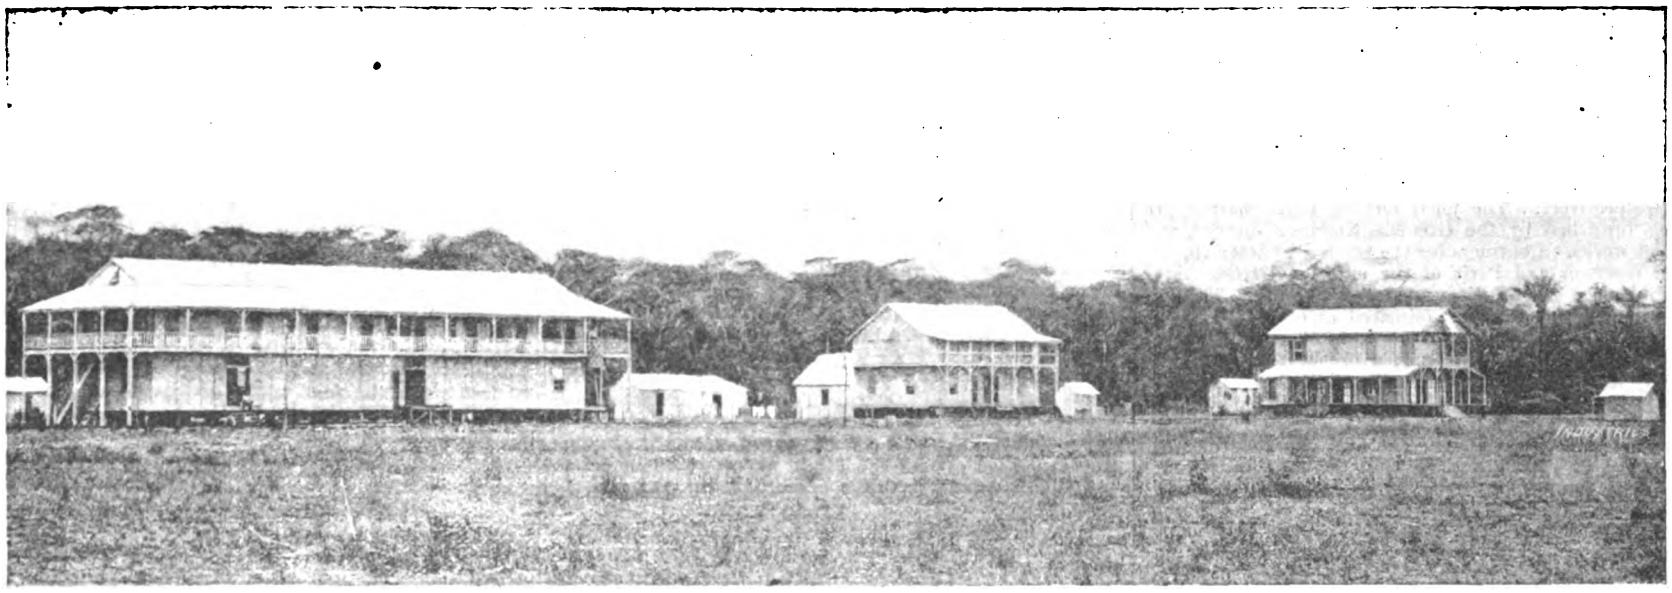

Fig. 11.—Headquarters of the Company's Staff Looking Westward.

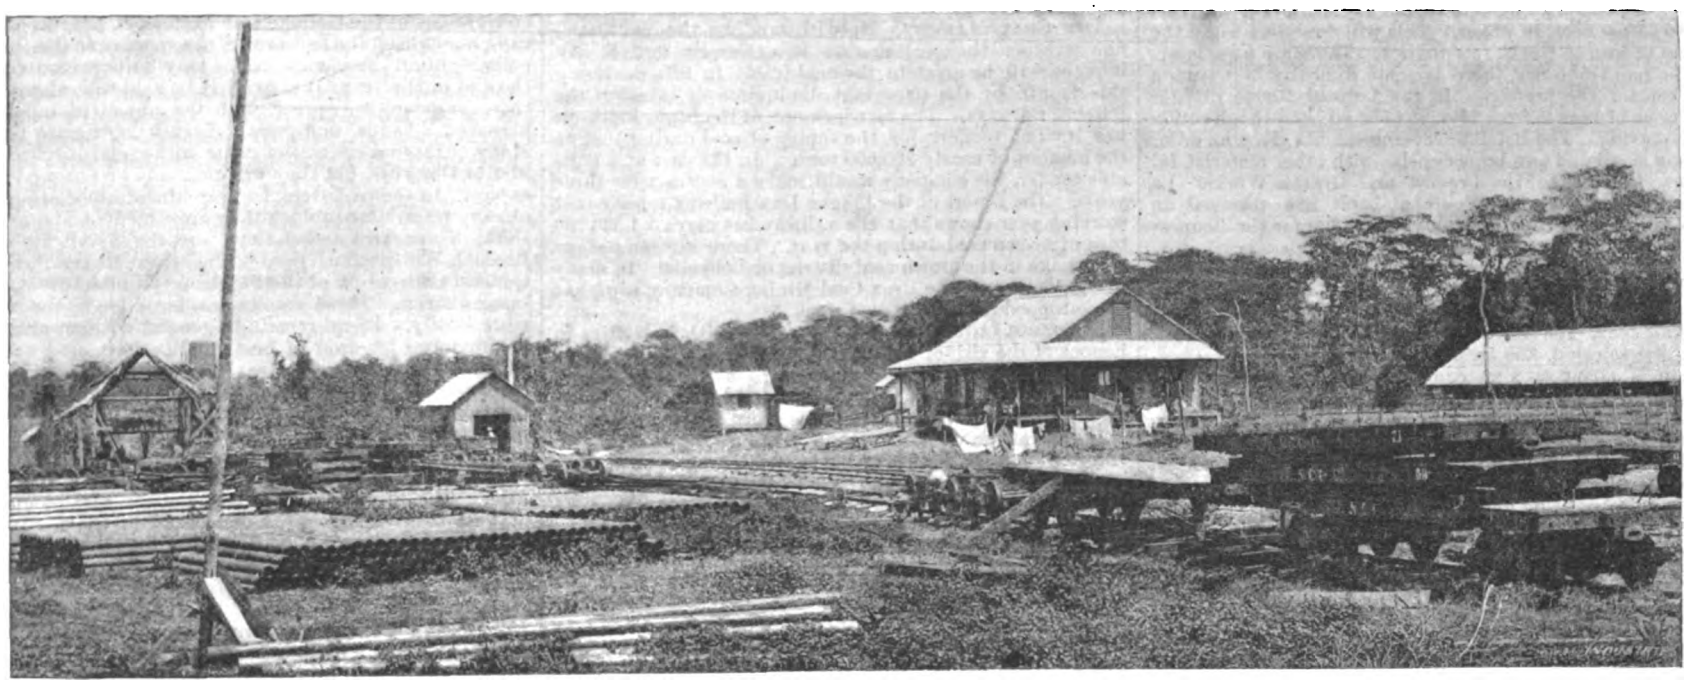

Fig. 12.—Railway Camp.

of itself, a very great undertaking, especially in such a climate as that of the isthmus. The cost of the whole work, including that necessary in the harbour of Panama and at Aspinwall, is estimated to exceed by nearly 50 per cent. that of the Nicaragua route."

It will be conceded that the authors of this report very shrewdly anticipated the nature of the difficulties which experience has shown to be connected with the construction of the Panama Canal. With respect to the route then proposed for the Nicaragua Canal, the same report says:—"No doubt exists as to the entire practicability of constructing an interoceanic ship canal *viâ* Lake Nicaragua. If the work were conducted with ability and honesty, it could be completed within a moderate period of time, and at a cost that would prove commercially profitable by the payment of tolls, moderate when compared with the loss of time, wear and tear, deterioration of cargo, insurance, &c., that belong to voyages *viâ* Cape Horn or the Straits of Magellan. The cost of construction of the canals and harbours with all their necessary adjuncts—locks 400ft. in length and 26ft. depth of water—may be set down as at least one hundred million dollars." As before stated, Mr. Menocal's latest estimate fixes the cost of construction at ninety million dollars, but this refers to a route improved in several important particulars as compared with that in contemplation at the time the report from which we have quoted was written.

The probable time occupied by steamers in passing through the canal is calculated to be about twenty-eight hours, made up as follows:—

			H.	M.
26·030 miles of canal, at	5 miles an hour...		5	12
21·619 ,, in the basins at	7 ,, ...		3	5
64·510 ,, in River San Juan, at	8 ,, ...		8	4
56·500 ,, in Lake Nicaragua, at	10 ,, ..		5	39
6 lockages, at 45 minutes each			4	30
Allowance for detentions in narrow cuts.....			1	30
Total time of transit.....			28	0

The illustrations which we give on page 532 and above, show some of the buildings which have been erected in connection with the canal works. Fig. 9 shows the storehouse and staff quarters situated at La Fé; Fig. 10 shows the hospital buildings which have been erected, looking westward; Fig. 11 shows the headquarters of the Nicaragua Canal Company at the works; and Fig. 12 shows the railway camp, which was rendered necessary on account of the railways to be constructed for the transportation of men and plant.

(To be continued.)

PETROLEUM AS FUEL IN LOCOMOTIVES.

Holden's method of using oil as fuel in locomotives has been introduced with great success on the State Railways in India. It has also been adopted by the Government of the Argentine Republic, where copious oil deposits are being developed. Recently a number of engines have been despatched to that country. There is not much apparent difference in the construction of these locomotives from those in ordinary use, as each has a tender, with the usual supply of coal, so that either coal or oil may be used as fuel as may be found most convenient, as Holden's injector does not interfere with coal burning. On the grate there is always a fire, partly of coal, but generally of a large part of limestone in small lumps or of broken firebrick. The oil passes through the nozzle of the injector at a great pressure, but very little of it falls on the limestone or firebrick fire, as the temperature is so high that it is burnt up quickly, and none of it passes to the ashpit below. The materials on the grate seldom require replenishing, as the oil is sufficient for the purpose. From some experiments which were recently made with a train of twelve carriages, on a run of 1,200 miles, it was found that the consumption of petroleum, coal, and wood was at the rate of 22lb. per mile, while a similar engine using coal alone, doing exactly the same work, needed 50 per cent. more fuel. This will be of especial importance in a country like Argentina, where petroleum can be got cheaply, and where coal costs about £4 per ton.

SHIPBUILDING IN GREECE.

During the year 1890 61 wooden sailing ships were built at Syra, in Greece, of a total tonnage of 8,673 tons, and valued at £73,640. This shows an increase of 34 vessels on the year 1889, the number constructed in that year being 27, of a total of 4,480 tons, and valued at £37,000.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 2nd June, 1891.

The Iron Market.—There was a slight decrease in the demand on the Paris market during last week, which may in part be accounted for by the bad weather having more or less interrupted building operations. The prices quoted are the same as in the previous week—namely, 140s. 6d. per ton for bars, and 148s. 6d per ton for joists. The market for the latter is strong, but both the above types of iron, if the order is of importance, can be obtained at 134s. and 142s. respectively. The joists on the Paris market are chiefly furnished by the Grenelle, Northern district, and Creusot works. Contracts for the section between the St. Cloud reservoir and Paris of the additional fresh water supply for the metropolis were awarded on the 30th ult. The value of this work is estimated at over £120,000, of which at least £40,000 is for iron work. The supplying of cast iron pipes for the maintenance of the water works in this city has been secured by the Pont-à-Mousson Works at 130s. per ton. The situation in the North remains unchanged; orders continue to be fairly plentiful, especially from the Paris market. An order for 500 tons of steel plates has been passed by the Société des Ateliers de Saint-Denis to a Maubeuge rolling mill. In the Meurthe-et-Moselle district prices continue firm, both as regards cast and wrought iron; a fifth blast furnace is being constructed at the Jœuf works; the Société de Montataire, which has two furnaces, has just blown out one, the stock of metal on hand amounting to 6,000 tons. In the Haute-Marne bars are quoted at 128s. 6d., and the general state of trade is satisfactory. The strikes in the Ardennes mentioned last week have nearly all come to an end, the masters in almost every case having agreed to an augmentation of from 20 to 35 per cent. in wages. This will doubtless cause the prices of iron to rise in this district. There are complaints in the nail trade that there is some difficulty in getting a market for the produce. In the Loire-et-Rhône district the price of bars is from 140s. to 144s. 6d., and the situation is improving. The Belgian Government has given an order for six small and two large cupolas with other material, for a new fortress, to the Creusot and Grüson Works. La Société de Commentry-Fourchamboult has received an order for iron work of the value of £22,800 for the Bourges and Cosne Railway.

Copper, Tin, Lead, and Zinc.—There has been little activity on the copper market during the past week, but quotations are slightly higher than they were—viz., best Chilian bars, £56 15s.; ordinary Chilian bars, £54 15s.; and best selected, £59 5s. per ton. The Minister of Commerce is about to sign contracts for the delivery of 90 tons of copper wire for telegraphic purposes. Tin has again fallen off in price as regards the Billiton, Banca, and Detroits marks, the first now being quoted at £98 18s., and the two latter at £100 8s. and £97 8s. respectively. There is very little doing in lead, and zinc has decreased in value, Silesian being quoted at £24 5s. per ton.

Proposed Increase of the Customs Duties.—The general discussion on the new Bill came to a close on the 22nd ult. The fees, as proposed in the first instance, have nearly all been raised, especially in the cases of machinery, tools, and manufactured goods. Raw materials, which are necessary for the existence of several branches of French industry, are naturally less heavily taxed. It now remains to be seen what further modifications may be made before the Bill becomes law, the present Government inclining to a more moderate scale of tariffs.

BERLIN, 1st June, 1891.

The Iron Market.—The following statistics have been published as to the production of pig iron by the blast furnaces in Germany, including Luxembourg, during the first quarter of 1891:—Puddled iron and spiegel iron, 419,735 tons; Bessemer iron, 94,718 tons; Thomas iron, 388,250 tons; foundry pig iron, 147,380 tons; making a total of 1,050,033 tons, as compared with 1,152,840 tons in the first quarter of 1890. In Upper Silesia there was an output of 115,700 tons, as against 128,032 tons. The total production of pig iron in Germany shows a diminution of 102,807 tons or 8·9 per cent. as compared with the corresponding period of the previous year, a diminution of 47,001 tons or 4·3 per cent. as compared with the preceding quarter, and a diminution of 7·9 per cent. as compared with the average. These results show the critical condition of the German iron market. The falling off in the sale of iron and steel which commenced in the middle of the previous year, and increased continuously up to the end of the year, became more accentuated, and it was not till last March that the blast furnaces were again in active operation. It may be concluded from these statistics that the manufacture of spathic iron is more remunerative than that of bar iron. The production of puddled iron and spiegel pig iron during this year amounted to 39·97 per cent. of the total quantity as against 44·5 per cent. in the previous year, the production of Thomas iron rose from 34·1 to 36·98, and the production of foundry pig rose from 11·8 to 14·03 per cent. At a recent general meeting of the Upper Silesian Rolling Mills Union, it was decided that two blast furnaces should be blown out in Upper Silesia. The total production of pig iron in Germany, including Luxembourg, during April, was 354,350 tons, of which puddled iron and spiegel iron amounted to 141,321 tons, Bessemer pig iron, 33,815 tons, Thomas pig iron, 134,226 tons, and foundry pig, 44,988 tons. The production in April, 1890, was 398,457 tons, and in March, 1891, was 370,018 tons.

New Sugar Refinery.—A new sugar refinery is about to be established by a syndicate at Hamburg, under the management of Messrs. Michaelles Brothers. The works, which are expected to have a yearly output of 25,000 tons, are being erected at Schulau, and will be completed in the beginning of 1892.

The Frankfort Electrical Exhibition.—During the first week this Exhibition was opened 29,773 persons visited it. Having in view the unfavourable weather, this is considered satisfactory.

VIENNA, 1st June, 1891.

The Iron and Metal Market.—There is no alteration in the state of the market since the previous week. The demand for materials for constructive purposes continues satisfactory, and the railways, which have lately shown very favourable balance sheets, are beginning to supply their wants for the present working year. The price of sheets is therefore advancing. The price of zinc sheets rose last week by 19s. 6d. per ton, so that the price now is £33 8s. 6d. at the works. With regard to the production of lead, the balance of the largest mining company of the lead mining union is very favourable. In the past year the company produced 4,113 tons of lead, an increase of 361 tons on the previous year; 6,010 tons of lead schlich and ore, a decrease of 317 tons; 1,349 tons of zinc ore, an increase of 611 tons. During the same period the works of the company made 529 tons of pig lead, 617 tons of lead shot, and 912 tons of lead oxide. Notwithstanding the generally increased production, the profit was less than in the previous year. It amounted to £15,608, which allows a dividend of 5 per cent.

The Coal Market.—Notwithstanding the continued fine weather the coal market is extremely active. An impetus will be given to the coal traffic in Silesia during this month by the important diminution of rates on the Silesian railways. The management of the State Railways has invited tenders for the supply of coal during 1892 to the amount of nearly 800,000 tons. In the case of a suitable tender, the company would make a contract for three years. The report of the Prague Dux Railway for the past working year shows that the railway has carried 1,330,280 tons of brown coal during the year. There are some signs of a strike in the brown coal district of Bohemia. In many pits belonging to the Brux Coal Mining Company work has been stopped during the past week.

Electric Lighting.—In connection with festivities in honour of the visit of the Emperor to Fiume an installation of more than 1,500 incandescent lamps and numerous arc lamps has been erected. 600 lamps of various colours are used to form a device, showing the arms of the monarchy.

International Exhibition of Photography.—An International Exhibition of Photography was opened here recently. The section devoted to British exhibits forms one of the greatest attractions in the Exhibition. From an artistic point of view the British exhibits are considered by experts here to be the best.

BRUSSELS, 2nd June, 1891.

The Iron Market.—Business shows a tendency to improve. The rise in prices at Glasgow has induced buyers to place their orders in view of a possible rise in this market. Prices, however, remain stationary, joists being quoted at £5 4s., and sheets at £6 4s. to £6 8s. The Franco-Belgian Company has received some important orders for locomotives and waggons for Egypt. The Dyle Baculan Company, the Industrial Company, and Messrs. Schlessin & Couillet have important foreign orders.

The Coal Market.—The coal market continues in an unsettled state. Screened coal is quoted at 9s. 7d. to 10s. 5d.; steam coal, 11s. 2d. to 12s.; household coal, 14s. 5d. to 16s.; coke, 14s. 5d.; small coke, 8s. 9d. to 9s. 7d. German coal, which was imported during the strike, maintains its position, and competition has been thus increased in view of the resumption of work after the strike. At Charleroi the leaders of the strike are trying to prevent the resumption of work. Wages, however, are now fairly high, and have been increased by 40 per cent. during the past two years. The number of workmen has also increased from 10 to 12 per cent.

Electric Lighting in Brussels.—The specifications for the electric lighting of Brussels have at last been published. The total power required for the system is 1,200 kilowatts. 1,000 lamps, of 16 candle-power each, are to be supplied for the Théâtre de la Monnaie by means of accumulators, 80 arc lights of 12 amperes at the Park Theatre, 120 arc lights of 9 amperes on the inner boulevards. Twice a year 700 lamps, of 16 candle-power each, will be required at the Town Hall on *fête* days. If the principal station is to be used for supplying currents of low pressure, it must be situated in the centre of the town at a distance of about 330 yards from the canal. The price of land in this part of the town is about £6 per square metre. If a secondary station should be decided upon in the upper part of the city, it will be situated near the Park Theatre, where the price of land is about £10 per square metre. The motors must be provided with all the latest improvements, so as to avoid accidents and ensure perfect working. The dynamos may be driven directly by the motors. The armature wires and commutators must not be heated by more than 50° C., and there must be no sparking at the brushes, whatever the load may be. The armature wires must also be easily accessible. With regard to accumulators, the output, the mode of construction, and the working must be specified. The connections will be preferably of brass, and the cables must be covered with lead, and supported on insulators. The transformers must be shown in place. The cables must be underground, and the total drop in the conductors must not exceed 1 per cent. The conductor must have a section of not less than 1 square mm. for every 2 amperes of current. Payment for the work will be made in three instalments—70 per cent. on the completion of the work, 15 per cent. a year afterwards, and the remainder on the final taking over of the work, on which date £800 will be paid for the cost of extending the service during the two previous years. Other particulars may be obtained on application to M. Wybauw, chief engineer for the lighting of the city.

Locomotives.—The Chemin de fer Grand Central has just ordered some large goods engines from the Société de Saint Léonard, Liège, for the goods traffic between Antwerp and Germany. The locomotives have eight coupled wheels, of 1·43 metre diameter, while the tenders have six wheels, of 1·15 metre diameter. The locomotives are to be ready by the end of this year.

DÜSSELDORF, 2nd June, 1891.

The Iron and Steel Market.—The demand has largely increased, but the average prices are not much higher than they were in the beginning of the year. An improvement in the prices of raw and finished iron is the more desirable, as the prices of coal are firm and relatively very high. With reference to the Rail Syndicate, the Convention of Westphalian Pig Iron Manufacturers, and other conventions of the German ironmasters, it has been generally announced in the German newspapers that a general collapse of all these conventions may be expected towards the end of the year. It may fairly be said that almost all of these rumours are spread with the object of influencing prices on 'Change, and greatly disturb legitimate dealing. Many of these conventions come to an end on December 31st of this year, but they will certainly be renewed before expiry. In the past week two prominent associations have already resolved to prolong their agreements to January 1st, 1893. These two associations are the Syndicate of the Rhenish-Westphalian Forge Pig Iron Makers and the General Convention of the Pig Iron Manufacturers of the same district. These resolutions have made the market more steady. Prices remain in general without alteration. White forge pig iron of best quality is quoted at about £2 13s., Thomas pig iron at £2 3s. 4d. c.i.f. Luxemburg, corresponding to about £2 10s. c.i.f. Ruhrort Harbour. The bar iron market is unsatisfactory, while the wire and iron plate trade has rather improved. The manufacturers of railway materials are well employed.

The Coal Market.—The coal market continues very firm. The State Railway management at Cologne was obliged to give the prices demanded by the Westphalian collieries for a lot of about one million tons of coals for locomotives. This is a decided victory for the coal producers. The miners' disputes appear to be settled as regards the immediate future. A large number of the men who were engaged in the recent strikes were dismissed from their work, and met with no aid from their fellow workmen or sympathy from public opinion.

The Late Mr. A. von Kaven.—Mr. A. von Kaven, who was closely connected with the foundation and management of the polytechnical school at Aix, died last week in that town.

Electric Lighting Station at Cassel.—On the 24th ult. the new central station at Cassel was put in operation for the first time. The power for the station is obtained by means of a turbine generating plant situated some 7 kilometres from the town. The whole of the installation has been carried out under the direction of Herr Oscar V. Miller. The turbines were supplied by Messrs. Briegleb & Hausen, of Gotha, the dynamos by the Maschinenfabrik Oërlikon, of Oërlikon, and the accumulators by the Hagenerfabrik.

Verein Deutscher Eisenhüttenleute.—The principal meeting of the German ironmasters' union is to be held at Siegen on the 21st and 22nd inst. On the 21st inst. there is to be a general reception, followed by a public dinner and conversazione. On the 22nd inst. visits are to be paid to mines in the district, to the Siegen machine works, and to the blast furnaces of the Cöln-Müsener Bergwerks-Verein at Creuzthal and the machine works of Messrs. Klein at Dahlbruch. Papers are to be read on the progress of the iron industry in the Siegen district; "On Mining," by Mr. Gerlach; "On Blast Furnaces and Rolling Mills," by Mr. Weinlig; and "On Foundry and Similar Work," by Mr. E. Klein.

AMSTERDAM, 1st June, 1891.

Steamship Companies.—As from June 1st the steamers of the Castle Line, starting from Flushing, will call every fortnight at Lisbon on the way out. It appears from the report of the directors of the Royal Steamboat Company that the twenty-three vessels forming the fleet in 1890 performed 262 journeys to various ports in Europe, against 244 journeys the previous year, conveying passengers and

Digitized by Google

303,250 tons of goods (in 1889, 290,860 tons). The total gross profit during last year amounted to £79,550. Deducting various charges and the working expenses, and also writing off £17,380 for depreciation, there remains an available balance of £13,797, out of which the shareholders receive a dividend of 9 per cent. The Company recently lost a steamer near Samos, and she is being replaced by a new vessel of the same capacity, which Messrs. Laing, of Sunderland, are now building and will deliver to the Company by September 1st next. Freights were good in 1890, but have since gone down again considerably.

CENTRAL BOARD OF COMMERCE AND INDUSTRY.—The Dutch Government is preparing to found a Central Board of Commerce and Industry in Holland, which will represent trade and industries in general, and the Chambers of Commerce in particular.

DUTCH CENTRAL RAILWAY.—The annual report of the Dutch Central Railway Company shows that the total receipts in 1890 were £72,069, an increase of £3,063 over the receipts in 1889, and the working expenses £31,598, an increase of £2,617; 447,944 passengers were carried, an increase of 37,069; and 154,115 tons of goods. The net profit was £5,327, after payment of debenture interest and providing for debenture sinking fund. The shareholders receive a dividend of 1¼ per cent.

STOCKHOLM, 30TH MAY, 1891.

THE HUSQVARNA MANUFACTURING COMPANY.—Few industrial concerns in Sweden seem to be better managed than the large Husqvarna Works, where large extensions are again being made. In its large amount of water-power Husqvarna possesses a great advantage, which has been further enhanced by recent important alterations. A large dam, of granite and cement, 30ft. high, has been carried across the river above the Husqvarna fall, and the level of the water above the dam is 250ft. above the level of the water in the Vettern lake. The Husqvarna Works are now able to utilise 225ft., which is the greatest height of fall used at any industrial works in Sweden. From the dam just referred to the water is carried through a wooden tube 1,000ft. long, which is nearly horizontal, and then through a tube of Bessemer steel plate, 300ft. long and 3ft. 3in. in diameter. Sufficient water will pass through this tube to represent 600 effective horse-power, and if the speed of the water be increased, the power increases to 1,000 h.p. This power is, as yet, only partly utilised, the two new turbines being of only 300 h.p. and 80 h.p. respectively. A third turbine of 100 h.p. will be used for the electric light installation, which will consist of about 1,000 16 candle-power lamps. Close to the turbine house a new workshop has been built, 212ft. long and 52ft. broad. This building consists of basement and two stories, besides a higher portion, to which the power from the turbines is transmitted through wire ropes.

CHRISTIANIA, 30TH MAY, 1891.

CONDENSED MILK.—Few industries have increased more continuously than the manufacture of condensed milk, and further extensions are contemplated. The following figures illustrate the growth of this industry, and show the export from Norway:—1879, 7,440kgr.; 1881, 440,662kgr.; 1883, 608,987kgr.; 1885, 818,096kgr.; 1887, 1,736,073kgr.; 1889, 2,415,864kgr.; 1890, 2,500,000kgr. The Anglo-Scandinavian Condensed Milk Company owns the Hamar Milk Condensing Manufactory, which last year dealt with about 6,000,000kgr. of milk. The price paid by the works is somewhat higher, on an average, than what the farmers can realise by dealing with the milk themselves. The same company is building another milk condensing manufactory at Sannesund, which will be ready in the autumn of the present year. Several other milk condensing manufactories are, however, in a more or less advanced stage. At the Toten Milk Condensing Manufactory it is intended to condense milk, if practicable, without the addition of sugar, and should this prove satisfactory the works would be able to give a higher price for the milk.

COPENHAGEN, 30TH MAY, 1891.

ELECTRIC LIGHTING.—The works in connection with the Copenhagen Electric Central Station, which is being built for account of the Corporation, are rapidly progressing, and are expected to be ready by November next. Messrs. Siemens & Halske, of Berlin, have taken over the main contract, the firm of Messrs. Burmeister & Wain, Copenhagen, supplying the engines. The boilers are partly of English and partly of German manufacture. The dynamos are in hand, and the cables expected to arrive in Copenhagen in the course of this month. The installation will comprise the lighting of the Houses of Parliament, the Royal Theatre, the Masonic Lodge, the Exchange, the Jewish Synagogue, the Town Hall, and the Art Museum. The applications from private people are very numerous, and the original plan has had to be extended once or twice on account of the great number of applications, so that the cost of the installation will, of course, much exceed the original estimate. It seems probable that the principal squares and thoroughfares will soon be lighted by electricity.

MADRID, 1ST JUNE, 1891.

AMALGAMATION OF RAILWAYS.—The excitement caused by the railway amalgamation schemes has not subsided. Important negotiations are supposed to be going on, but at present they are kept strictly secret. The arrival of M. Léon Say, the French financier, is supposed to be connected with some of the proposed arrangements, as he is connected with the system, which is under the control of the Rothschilds. The proposal to bring forward a law which would introduce a lowering of rates on the railways has not been facilitated by the Minister of Public Works, and this delay gives rise to much comment. The influence of those who control the present railway systems is evidently the chief factor in preventing the introduction of such a Bill. A question was asked in the Cortes on this subject, and the Minister replied that he was at present considering the matter, but it is stated that no efforts have yet been made to obtain the necessary information.

DISCOVERY OF COAL AT ALBANCHEZ.—It is reported that coal has been found at Albanchez, in the province of Almeria, in such a position as to admit of easy working. The discoverer has, however, taken up only a few acres of land, which would make it probable that the discovery is not of great importance. Coal is very dear in the province of Almeria, and the production of even inferior coal would be very advantageous in developing the mining and metallurgical industries of that district.

TREATMENT OF LEAD ORES.—It is intended to establish a plant on the system of M. Castelnau in one of the lead districts in order to treat what is now considered as valueless with the present means of concentration. This process is being energetically promoted, and if the machine accomplishes what is expected there will be a large increase in the production of lead within the next few years.

THE CACERES PHOSPHATE MINES.—Though these mines were offered for sale at the very low price of £20,000, they have not yet found a purchaser. The stock of phosphate of from 35 to 40 per cent. is 31,800 tons. In addition to the mining plant there is a factory with sulphuric acid chambers for the manufacture of superphosphates.

SHIPMENTS OF BILBAO ORE.—There is an improved demand for Bilbao iron ores. The shipments of ores during the first fortnight of May were nearly equal to those of last year, so that the decrease has not continued at the same rate as at the beginning of the year.

ELECTRIC LIGHTING.—Installations of electric lighting have been made during the month of May at Jaen and at Aranjuez. These places had not been lighted by gas. At Jaen steam power is used, and at Aranjuez the water power of the Tagus is utilised. The corporation of Avila, the capital of a small and poor province, now invites tenders for a ten years' contract for public and private electric lighting. This town has not been lighted with gas, and electric lighting will therefore meet with no competition. In most cases the electric light can be supplied at a cheaper rate than gas in those places where new gas works would have to be make, and where there is no demand for coke.

ROME, 1ST JUNE, 1891.

THE MERIDIONALI RAILWAY COMPANY.—At the general meeting of this company, held in Florence on the 15th ult., a dividend of £1 9s. per share was declared, of which £1 had already been paid, and 9s. is now payable. The shareholders present represented 88,797 shares. The report of the general manager, Mr. Borgnini, states that the economical crisis which prevented the natural progress of the railway traffic in 1889, was also felt in 1890, during which year the traffic receipts of the principal line were only increased by £33,080, and those of the secondary line by £1,320. The receipts of the first three months of this year, however, show considerable improvement. The amalgamated length of the two lines is about 3,242 miles. The total income of the two lines, after deduction of the working expenses, is as follows:—

Principal line	£3,986,606
Secondary line	270,076
Total	£4,256,682

The total capital of the company up to December 31st, 1890, amounted to £31,813,480. Deducting from this the outlay on the construction of the lines and on the rolling stock, amounting to £30,754,992, it appears that the total capital undisposed of on that date was £1,058,488. The estimates for 1891 show an income of £3,338,160, with an expenditure of £2,612,000, thus leaving a balance of £726,160. The net profits for the past year amounted to £156,008.

ANOTHER SHIP CANAL.—A ship canal, to connect Venice with the Gulf of Spezia, is now under consideration. Its length, according to present estimates, would be 273 kilometres (about 170 miles), and its average breadth 75 metres (about 246ft.) There will be in all 73 locks, and the cost of construction is estimated at about £52,000,000.

NEW YORK, 23RD MAY, 1891.

AMERICAN COMPOUND LOCOMOTIVES FOR BRAZIL.—The Baldwin Locomotive Works have received an order for twenty compound locomotives for export to Brazil. The order comprises six different classes of lomotives, half being for broad gauge lines and half for narrow gauge lines. There are four 65-ton Consolidation freight locomotives, three 50-ton express passenger locomotives, and three 50-ton Mogul locomotives for the standard gauge lines, and the same number of engines and the same types for the narrow gauge lines. The Baldwin Works have built or have under order at this time forty compound locomotives, and they have assumed a regular place in their output. The firm is providing by special machinery for the rapid and economical finishing of the cylinders.

A NEW LATHE.—Messrs. W. F. & John Barnes & Co., Rockford, Ill., have completed and are using, in their own shops, a very ingenious and convenient lathe. The speed is regulated by a disc, varied from very slow to extremely rapid, and the motion can be instantly reversed regardless of speed. The feed gear has also a disc attachment, giving many variations of speed, as also reversing the direction of the feed instantly.

IRON PIPE MANUFACTURE IN THE SOUTH.—The first iron pipes made in the South—twenty-five waggon loads—was despatched from Bessemer, Alabama, to the North on the 11th inst.

PREVENTION OF COLLISIONS ON RAILWAYS.—A simple and ingenious invention by Mr. W. H. Waddell, which has been successfully tried on a section of the Baltimore and Ohio Railroad, has attracted some attention. It is intended to prevent accidents by giving to the engine driver an unmistakeable warning, conveyed as follows:—A secondary track, laid in sections of desired length, is laid inside the regular track on insulated posts, a brush connecting with a battery in the cab. When two trains are in the same section, the circuit is completed, and the alarm given. The cost of the apparatus, including 12lb. rail, would not exceed £140 per mile.

REMOVAL OF STEAM PIPES FROM BROADWAY.—The Broadway Railroad Company, of New York, City, has made a contract with the Steam Heating Company, by which the latter agrees, in consideration of the payment of £20,000, to abandon its distributing pipes on part of Broadway before September 1st. The steam pipes have been continually breaking, and require constant opening of the streets, and the Broadway Company, which is building a cable road, has declared itself willing to pay this sum, to do away with this nuisance, which would seriously interfere with its business.

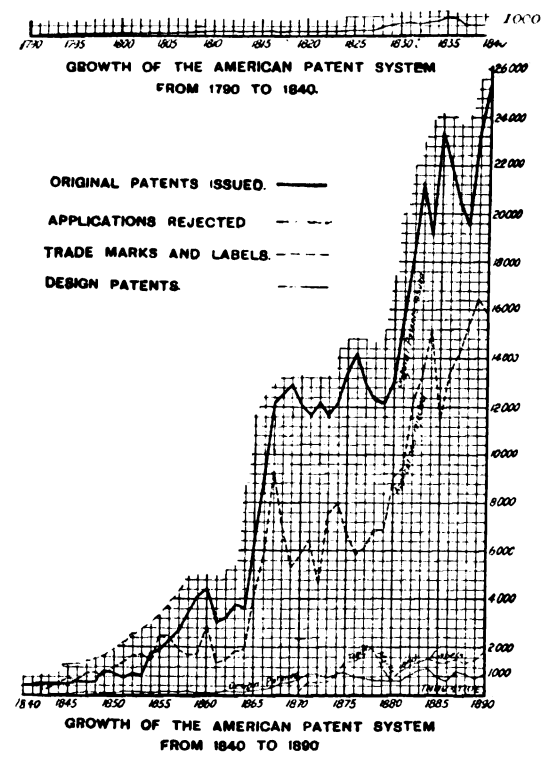
PHILADELPHIA, 22ND MAY, 1891.

THE COKE TRADE.—The Stourville and Eagle plants in the Connelsville regions have resumed work with a fair number of their former workmen. The manufacturers now have 5,000 ovens burning, and more than that number of men at work. But the strikers are still hopeful, and believe they may yet succeed. The Knights of Labour Convention in Scottdale decided to continue the strike six weeks longer. The manufacturers have refused to confer with a committee appointed by the Convention to compromise the differences. A dispute has been caused between the Knights of Labour and the United Mine Workers by the refusal of the former to grant the latter an equal representation in the Convention. As a result, the United Mine Workers' officials have issued an order for the men to return to work. Large numbers of men have returned.

UNSUCCESSFUL TESTS OF THE "VESUVIUS'" GUNS.—The tests of the guns on the dynamite cruiser "Vesuvius," made in Chesapeake Bay on the 20th inst., appear to show that the long brass guns are not satisfactory. The tests have demonstrated that the guns can be fired and shells of various weight sent various distances, which, however, can be only roughly estimated. No dynamite, gun-cotton, or explosive of any kind has been fired, the test being simply for accuracy, and they have shown that the guns in this respect are not a success. Of the six shots fired, only one came near enough to the target to inflict any damage. It is expected that the board of examiners will recommend the removal of the dynamite guns and the fitting of the vessel with torpedo equipment.

RAILROADS.—A mortgage of £6,200,000 has been given by the Chicago, Rock Island, and Pacific Railroad Company to the United States Trust Company, and filed at every country seat through which the road runs. The mortgage is to run for fifty years.—The Philadelphia and Reading Railroad Company has made a thirty-year contract for the anthracite tonnage, amounting to 1,500,000 tons per year, with Messrs. Coxe Bros. & Co., beginning October 1st.—The annual report of the Burlington, Cedar Rapids, and Northern Railroad for 1890 shows gross earnings of £660,796; working expenses and taxes, £457,567; net earnings, together with other income, cash assets in 1889, make total receipts £231,478.

END OF MINERS' STRIKE.—The strike against a reduction in wages, begun thirteen months ago by 3,000 miners of the Pennsylvania and Westmoreland Gas-Coal Company at Irwin, Pa., has been declared at an end, and the men will return at owners' terms. During the past five months the mines have been worked to nearly their full capacity by non-union men.



LOCK-OUT CAUSED BY SIX MEN.—Six men, known as the drag-outs, hook-ups, and carters, have struck at the Brooke Iron Company, at Birdsboro', Pa., for an increase of from 6¾c. to 8c. a ton. Owing to the action of these men, whose positions cannot be filled, 400 workmen have been thrown out of employment during the past week.

PENCOYD IRON WORKS.—The situation at the Pencoyd Iron Works is gradually improving. The departments recently shut down have resumed, and are in full operation on single or day turn.

Digitized by Google

THE AMERICAN PATENT SYSTEM.

As the recent anniversary of the establishment of the American patent system has aroused a considerable amount of public interest, the accompanying diagram, which has been taken from our American contemporary, the *Engineering News*, showing the growth of the system from 1790 to 1890 inclusive, will no doubt be found of considerable interest to our readers. The diagram requires little description, but we may mention a few of its most important features. From the date of the first American patent, July 31st, 1790, to 1836, a period of

forty-six years, the total number of patents granted was 9,957, or an average of 216 per annum; from July 28th, 1836, to the end of 1881, a period of forty-five years, 251,685 patents were granted, giving an average of 5,593 per annum. During the seven years 1882–88 the number of patents issued has been at a uniform rate of 20,000 per annum; and at the present time the average rate of issue is about 25,000 per annum. Of the 450,000 patents issued since the establishment of the system over one half of these have been brought out during the past eleven years.

THE ROYAL NAVAL EXHIBITION.

QUADRUPLE AIR COMPRESSORS FOR H.M.S. "ROYAL ARTHUR."

Amongst the multifarious arrangements provided in the equipment of the modern war vessel, not the least interesting and important are the air-compressing machinery and adjuncts for charging torpedoes. Two manufacturers of the requisite special plant—viz., Messrs. Maudslay, Sons, & Field, Limited, Lambeth, London, and the General Engine and Boiler Company, Hatcham Iron Works, New Cross, London—exhibit specimens of their manufacture. The former company has on view one of the three air-compressors they are supplying to the first-class protected cruiser "Royal Arthur," one of the nine vessels of this type now building for Her Majesty's Navy. On page 540 we give an illustration showing a front elevation of this air-compressor, in which all the latest improvements are adopted to ensure durability, minimum wear and tear, without undue weight of material. The principal castings and forgings are of steel, the three main columns supporting the air-compressor being independent, of ample size, and of forged steel fitted into sockets cast in the bed-plate, and also in main part of the compressor proper. The steam cylinders, 9½in. diameter, 4in. stroke, are three in number, each receiving high-pressure steam, and above each is worked direct three compressing rams, respectively 7⅛in., 6½in., and 2¾in. diameter, each of which gives four compressions for one revolution of the engine. The air is drawn into the pumps on the down stroke of the engine, and on the return stroke the air is compressed into an annular space between the bush which cases the pump piston and the wall of the compressor cylinder. On the next stroke the air is further compressed into another annular space of still smaller compass, and from thence, after further compression, it passes into the reservoir. The four operations in compression, thus described progressively, when once the machine is at work are carried on simultaneously with each pump at one revolution of the engine.

In case of partial or serious breakdown of two of the sets of air pumps and two of the steam cylinders, still, whichever were the pumps or engines disabled, the remaining engine could continue to drive the undamaged pump. The air-pump cylinders are completely surrounded by a jacket, through which water is constantly kept flowing, and the compressed-air discharge pipe also passes through water on its way to the reservoir.

The three sets of pumps in the triple-compressor we illustrate are together capable of supplying 30 cubic feet of air compressed to a pressure of 1,700lb. per square inch in seventy minutes, the steam cylinders working with a maximum pressure of 90lb. per square inch. The total weight of one set of pumps and engines is about 25 cwt. After being compressed, the air is stored in reservoirs each consisting of a series of steel tubes, fifty in number, 3in. in diameter and 6ft. in length, and from thence is conveyed through thick copper pipes to the torpedoes requiring to be charged.

Messrs. Maudslay, Sons, & Field have also a number of high-class working models of marine engines, besides other objects of interest amongst their exhibits, to which we hope, later on, to refer.

FEDERATED INSTITUTION OF MINING ENGINEERS.

A general meeting of the members of the Federated Institution of Mining Engineers was held in London on the 28th and 29th ult., at the Institution of Civil Engineers. The proceedings opened with an inaugural address, delivered by the octogenarian President, Mr. T. W. Embleton, who gave an interesting account of the progress that had been made in mining and other industries since 1826. Sir George Elliot proposed a vote of thanks to the President for his address, and dwelt upon the difficulties with mechanical appliances which had to be contended with sixty years ago.

Mr. W. Foggin, of Durham, then proceeded to read the first paper, which was on "Locked Coil Wire Ropes." In this the author described the invention of Messrs. Latch and Bachelor to protect the inside coils by interlocking the outside ones. Many of these ropes were being used, some of them being over seventeen tons in weight, and comparisons were made with ropes of the ordinary construction. It is to be regretted, however, that the author gave no statements of comparative cost, and that he did not institute a comparison with some of the ropes of special construction now largely used. In the discussion that followed the reading of the paper no special information resulted.

The second paper read was on "The Coalfields of New South Wales," by Mr. G. B. Walker, of Barnsley. The mineral resources of Australia, he pointed out, were as yet but partially explored; but so far as coal was concerned the principal deposits lay within the colony of New South Wales. The geology of the coalfield was briefly described, and a large amount of statistical information brought forward. Notwithstanding the decrease in the price of coal, the improvement in the coal trade of the colony was regarded as eminently satisfactory.

This paper was followed by one on "The Coalfields of Australasia," by Mr. S. H. Cox. This paper passed over much of the same ground as Mr. Walker's. Mr. Cox, however, left the commercial aspects of the coalfields, and gave an instructive account of the geological structure of the colonies. The conclusions to be drawn from the facts summarised by the author are, that both Australia and New Zealand are fortunate in the possession of extensive coalfields, which are being developed in accordance with the requirements of the trade. Experience shows that it is not only those mines in which the coal is of the best quality that pay for working, or, indeed, that return the best interest for the money expended upon them. There can be little doubt that in the future the principal development of the coal-mining industry will be between the Newcastle and Lake Macquarrie fields to the north, and the Illawarra field to the south. The opening of mines below Sydney, an event which is only a question of time, will convert the whole district into one of the largest and probably best-paying coalfields in the world.

Mr. Binns, Inspector of Mines for New Zealand, having just arrived from the colony, was able to correct a few of Mr. Cox's statements.

The fifth paper read was by Mr. J. McLaren, of Leeds, on "The Economical Use of Steam in Colliery Engines." In this he gave the results of a series of trials carried out at his works in Leeds with a set of triple-expansion engines. The results show that, where sufficient care in construction is exercised, the same economy can be obtained with engines and valve gear of the old stereotyped pattern as had hitherto been considered obtainable only with complicated and expensive valves and valve mechanism.

The last paper read on the 28th ult. was by Professor F. Clowes, of Nottingham, and Mr. J. Ashworth, of Derby, on "The Detection of Firedamp." In this paper the authors showed that, by means of a benzene flame in Ashworth's Hepplewhite-Grey safety lamp, the detection of small quantities of firedamp is possible. With 0·25 per cent. of firedamp in the air, the cap on the flame is quite appreciable. With an ordinary safety lamp, however, quantities of gas less than 2 per cent. cannot be detected. As it is now generally admitted that coal dust is explosive when 0·5 per cent. of gas is present, the importance of this invention will at once be admitted. With the new benzene lamp the following observations have been made:—

Percentage of Gas.	Length of Cap. Millimetres.
0·5	7
1·0	10
2·0	15
3·0	20
4·0	25
5·0	30

Owing to the absence of luminosity in the benzene flame, the indications obtained with this lamp exceed in delicacy those obtained with any other lamp except the Pieler alcohol lamp. For low percentages of gas, the authors find that it is advantageous to colour the outer surfaces of the lower portion of the glass of the lamp, as the eye is thus assisted in defining the gas cap. In the tests described vermilion was the colour used.

In the discussion, Mr. Walton Brown stated that he had found that the Pieler safety lamp gave superior results, as the cap on the flame was greater for 0·25 per cent. of gas than it was for 2 per cent. with the Grey lamp.

Mr. H. W. Hughes, of Dudley, pointed out that inasmuch as the Pieler lamp was not safe in currents of ordinary velocity, it could not be regarded as a safety lamp, but should be classed with delicate firedamp detectors. He had made practical tests with every kind of safety lamp, and found that the Hepplewhite-Grey showed the presence of gas where no other lamp would.

The proceedings on the 29th ult. commenced with the reading of a paper by Mr. J. Yates, on "An Electrical Safety Apparatus for Cages." This ingenious invention was described by the aid of a model and diagrams. A copper wire in the centre of the winding rope conveys an electric current to electromagnets which hold back grips, pulling against the tension of a spring. When the current is broken by a fracture of the rope, the springs come into action, and the grips fasten against the guides. The author claims that this invention is preferable to the ordinary safety catches which are kept out of action by the tension of the winding rope, in that it is not liable to come into action by slacking of the rope.

The next paper read was a valuable report on "The Fumes produced by the Explosion of Roburite, Tonite, and Gunpowder," by Dr. P. P. Bedson, of Newcastle, with a medical report by Dr. D. Drummond and Dr. G. H. Hume. Dr. Bedson finds, after careful experiment, that the fumes produced by roburite and tonite are less deleterious than those produced by gunpowder. Indeed, if three minutes are allowed to elapse after the explosion, none of these explosives render the air of a mine so impure as that in the gallery of a theatre. The medical experts who reported on the matter find that in every case of alleged injury from the fumes of these explosives, the symptoms were entirely due to pre-existing natural causes.

In the discussion which followed the reading of this paper, special reference was made to the indebtedness of the Institution to the Coal Masters' Association of Northumberland and Durham, who caused the experiments to be made, and also allowed the Institution to publish the report.

The last paper on the programme was "Notes on Coal Dust," by Mr. H. Hall, H.M. Inspector of Mines. In this he gave an account of his experiences made for the Home Secretary, and of some experiments made to determine whether the so-called flameless explosives gave a flame. These experiments show that if insufficiently tamped all these explosives give flame. With several inches of tamping, roburite and carbonite gave no flame.

In the discussion, Mr. W. M. Atkinson, Mr. A. L. Steavenson, and Mr. W. Cochrane agreed in considering that coal dust was capable of producing explosions in the absence of inflammable gas. Mr. Walton Brown, however, agreed with Mallard and Le Chatelier in believing that firedamp was required in order to propa-

Digitized by Google

gate the explosion. Throughout the discussion no reference was made to the experiments made by Mr. W. Galloway, the originator of the coal dust theory, who, some years ago, in his papers read before the Royal Society, brought the matter into prominence in face of great opposition.

During the meeting several works were open to the inspection of the members, and excursions were arranged to the Millbank Street Station of the London Hydraulic Power Company, to the City and South London Railway, and to the Deptford Station of the London Electric Supply Corporation. An excursion was also arranged to visit a shaft being sunk by the freezing process at Pont-à-Vendin, near Lille. In view of the shortness of the notice given, only five members were able to avail themselves of the invitation, and it was decided to postpone the visit for a month.

THE SKILLED LABOUR MARKET.

ACCORDING to reports furnished to the Board of Trade by twenty-one trade societies, with a total membership of 242,831, 6,548 were unemployed during the month of April as compared with 7,000 during the previous month. The reduction in the proportion of unemployed from 2·85 to 2·69 per cent. was caused by increased activity in the building trades. Employment in the boot and shoe and other branches of the clothing trades is reported as satisfactory, but there is some decrease of activity in the shipbuilding, engineering, and other branches of the iron trades. The number of strikes has increased from fifty-three in the month of March to seventy-seven in the month of April. Of these strikes, sixteen were connected with the building trades, in which an increased demand for labour has led to an increase in the number of strikes. There were ten strikes among iron, steel, and brass workers, and nine strikes in the cotton trade. There was an important stoppage of work in the Manchester district for the purpose of obtaining a reduction of one hour per week, in which fifteen firms were involved. On the whole, there has been an improvement in the condition of industries, though some of them show a falling off during the month of April.

SHIPBUILDING NOTES.

ON the 23rd ult. Messrs. Wm. Hamilton & Co., Port Glasgow, launched the steel screw steamer "Alice Taylor." The vessel has been built to the order of Mr. Robert Taylor, shipowner, Dundee, and is intended for coal traffic between Sunderland and Dundee. The engines have been constructed by Messrs. George Clark, Ld., Sunderland. The dead-weight carrying capacity is 700 tons. The engines are 1,400 i.h.p.

ON the 23rd ult. the s.s. "Maria," which has been built by Messrs. J. Priestman & Co., of Sunderland, for Mr. A. Embiricos, Braila, made her trial trip. The principal dimensions of the vessel are:—Length, 302ft.; breadth, 40ft.; depth, moulded, 19ft. 6in. The engines, of the triple-expansion type, with cylinder diameters 23in., 37in., and 59in., by 42in. stroke, were made by Messrs. Westgarth, English, & Co., Middlesbrough. The vessel was fully loaded, and a speed of 10¼ knots was obtained at the measured mile, and, the trial trip being in every way satisfactory, the vessel left for the Mediterranean.

MESSRS. GOURLAY BROS. & Co. have recently launched a steel screw steamer for the Pacific Steam Navigation Company, Liverpool, to be used for towing purposes at Valparaiso. The vessel is of the following dimensions:—Length, 105ft.; breadth, 22ft. 6in.; depth of hold, 12ft. The vessel has compound engines of 300 i.h.p.

ON the 2nd inst. the new war cruiser "Melampus," built and engined by the Naval Construction and Armaments Company, Ld., Barrow, sailed from that port for Portsmouth. Before leaving Barrow a preliminary trial of the engines was made, with most satisfactory results. The "Melampus" is a sister ship to the "Latona," which was also constructed at Barrow. The Barrow shipbuilders have been by far the most expeditious in their execution of the orders for seventeen of these cruisers, which were placed with private builders at the close of 1889. They secured an order for three vessels, and they have now handed over their second vessel before the Clyde, Thames, or Tyne builders have been able to deliver their first. The "Melampus" was launched on August 2nd last year. Her dimensions are:—Length, 300ft.; beam, 43ft.; and depth, moulded, 22ft. 6in., having a displacement of 3,400 tons on a mean draught of 16ft. 6in. After the preliminary trial she was handed over by Mr. A. Adamson, managing director of the Barrow yard.

THE twin-screw steamer "Scot," which has been constructed by Messrs. William Denny & Bros., Dumbarton, for the Union Steamship Company, of Southampton and London, for their South African mail service, completed her trials on the Firth of Clyde last week with most satisfactory results. On a preliminary trial over the measured mile at Skelmorlie a mean speed of 19·62 knots was realised, at a draught of water of 19ft. 9in. The draught was subsequently increased to 23ft. 2in., when the recorded mean speed of six runs over the measured distance was 19·176 knots. On the 30th ult. the "Scot" left the Clyde for Southampton, calling at Plymouth *en route*. The passage from the Clyde to Holyhead was performed at a speed of 18 knots and from the latter place to the Longships Light at the high average of 18·6 knots. The dimensions of the "Scot" are as follows:—Length, over all, 500ft.; breadth, 54ft. 6in.; and depth, 27ft. 6in.

Notices of Meetings.

THIS WEEK.

ROYAL INSTITUTION.—Friday, June 5th, at 9 p.m. Lecture on "The Implications of Science," by Mr. St. G. J. Mivart, F.R.S. Saturday, June 6th, at 3 p.m. Lecture on "The Scientific Study of Decorative Colour," by Professor A. H. Church, F.R.S.

GEOLOGISTS' ASSOCIATION.—Friday, June 5th, at 8 p.m. Papers to be read: "On Some Hill Gravels North of the Thames," and "On the Geology of Nettlebed Hill, near Henley," by Mr. H. W. Monckton and Mr. R. S. Herries; "The Geology of Devizes, with Remarks on the Grouping of Cretaceous Deposits," by Mr. A. J. Jukes-Browne.

NEXT WEEK.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, June 8th, at 8 p.m. Sessional meeting.

PRICES CURRENT, 3RD JUNE, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.		Best. £ s. d.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: Since our report of the 27th ult. Chili bars have still further advanced in value, owing to increased speculative inquiry. Some heavy purchases of raw copper have been made recently, and stocks generally have decreased. During the last few weeks the market has therefore improved. Quotations to-day are £52 to £52 7s. 6d. cash, with steady market. Manufactured firm, at £66 to £67, "strong."

TIN has also improved, foreign having advanced about 30s. to 35s. during the week.

LEAD: Unchanged, with small inquiry.

SPELTER is dearer, and likely to advance, as supplies are small and stocks very low everywhere.

IRON ORE.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: There is no change in values of the articles controlled by the Alkali Union. The inquiry for bleaching powder and caustic soda is perhaps scarcely so brisk, but prices are well maintained. Sulphate of copper is dearer, and the market is strong for prompt delivery. Benzoles are easier, and carbolic acids continue very depressed. Sulphate of ammonia has a rather better tone.

WE have received a copy of the first number of a new monthly journal, entitled *The London Phonographer*, which is to be devoted to all matters of interest in connection with shorthand and typewriting. One of the useful features of the journal, although probably somewhat out of its strict scope, is a list of "commercial terms in four languages." The journal is well printed, and should, we think, meet with success.

HOME INDUSTRIES.

LONDON, 4th June, 1891.

The Money Market.—The feature of the money market is still the endeavour to maintain rates at a point sufficient to attract gold here from other centres, while at the same moment money is abundant enough to seem to justify comparative ease. With the Continent still anxious for gold, the Bank of England cannot afford to let the value of money here fall below the rates current in other centres, or an outward flow would at once begin, and the advantage gained with such difficulty would be frittered away. Of course there is no desire to keep money unnecessarily dear, but simply to maintain effectively a minimum rate which may secure the preservation and augmentation of our gold reserve. The tone of the stock markets has improved distinctly during the week. Home railway stocks still excite little interest and are generally dull. Americans, on the other hand, begin to show unequivocal signs of returning strength, and the Canadians follow suit. The foreign department is still uncertain and nervous, though the Paris settlement has proceeded more easily than was anticipated. Portuguese, Spanish, and Italians are undecided, with a weak tendency. Argentines are virtually unsaleable since trouble broke out afresh in the Buenos Ayres Bolsa, and a good deal of anxiety is felt as to the future of these securities. The market has been again indulging in rumours as to the position of leading firms, but without any justification. The miscellaneous and mining markets are still without feature.

The Institution of Civil Engineers.—The annual general meeting of Corporate Members "to receive and deliberate upon the Report of the Council on the state of the Institution, with the Annual Statement of the Accounts, and to elect the Council and Officers for the ensuing year," took place on the 26th ult., Sir John Coode, K.C.M.G., the President, being in the chair. The effective increase in the roll of the Institution during the past year was 247. There had been elected 2 honorary members, 51 members, 291 associate members, and 7 associates, and 3 associate members had been restored to the Register. Only 107 names had disappeared from the list. The number of members of all classes, students excepted, on the 31st of March last, was 5,150, as against 4,903 on the same day last year, representing an increase at the rate of 5 per cent. The student class had somewhat diminished in numbers, the total being 914 on the 31st of March last, as against 969 on the 31st of March, 1890. This was not due to any diminution in the numbers admitted, but to the fact that more students had been elected Associate Members during the year, and that a greater number had become ineligible to remain in the class by reason of having passed the limit of age—namely, twenty-six years. Adding the students to the number on the Register, the gross total on the books was 6,064. From the balance-sheet appended to the Report, it appeared that the receipts during the financial year amounted to £24,274 8s. 11d., and the payments to £23,351 1s. 9d. The Council congratulated the members that, as the result of protracted litigation with the Inland Revenue Department, the House of Lords had upheld the judgment of the Court of Appeal, that the whole of the property of the Institution was exempt from Corporation Duty under the Customs and Inland Revenue Act of 1885, on the ground that it was legally appropriated and applied for the promotion of education and science. At the first meeting of the newly elected Council of the Institution of Civil Engineers, the following officers were re-appointed:—Mr. H. L. Antrobus, as treasurer; Dr. Wm. Pole, F.R.S., honorary secretary; and Mr. James Forrest, the secretary.

Institution of Mechanical Engineers.—At the summer meeting of this Institution, which is to be held in Liverpool, Mr. Joseph Tomlinson, the President, and the Council and members of the Institution will be received by the Mayor of Liverpool, Mr. J. B. Morgan, the vice-chairman, Mr. T. B. Royden, M.P., and other members of the local committee, on July 28th, in St. George's Hall. During the meeting of the Institution visits have been arranged to the Cunard R.M.S. "Aurania," the White Star R.M.S. "Majestic," to the Inman and International R.M.S. "City of Paris," to the Walker engineering laboratories, the works of the Mersey Docks and Harbour Board, the Liverpool Overhead Railway; Messrs. Laird Brothers' Shipbuilding and Engineering Works, Birkenhead; the Mersey Tunnel Railway and Works; the locomotive works of the Lancashire and Yorkshire Railway Company, Horwich; the Manchester Ship Canal; and the Liverpool Corporation New Water Works, Vyrnwy. The Institution dinner will be held on Wednesday, July 29th.

Society of Engineers.—At a meeting of this Society, held on the 1st inst., Mr. W. N. Colam, President, being in the chair, a paper was read by Mr. John Kerr on "Portable and Pioneer Railways." The author disclaimed any intention of entering into the debateable ground of Narrow *versus* Broad Gauge Railways, but dealt with railways suitable to meet the requirements of factory, mine, plantation, or for an absolutely new and undeveloped country. The author strongly recommended, for the development of the newly acquired territories in Africa, the adoption of pioneer railways, and described the class of railway recommended, and gave particulars of the cost and construction and carrying powers. Reference was made by the author to pioneer lines having paved the way for a main line railway. Pioneer lines could afterwards be removed further a-field, or be used as feeders for the main line. The author said that it would be foolish to put down a pioneer railway where the traffic would warrant the construction of a heavy line.

Shallow-draught Steamers for East Africa.—The Portuguese Government are at the present time putting together some shallow-draught gunboats for service on the Pungwe River, in East Africa, which district is now in a disturbed state. Messrs. Yarrow & Co., Isle of Dogs, Poplar, London, E., who constructed them, have only lately despatched some additional machinery to fit them for the service.

Royal Alfred Aged Merchant Seamen's Institution.—In connection with the present Naval Exhibition, the claims of this Institution, which was founded in 1867 to give to aged merchant seamen, when destitute and friendless, either a home or a pension, seem to deserve recognition. There are now 100 inmates at the Home, Belvedere, Kent, and there are 229 out-pensioners receiving £12 a year. A dinner in support of the claims of the Institution is to be held on the 10th inst. at 7 p.m., at the Hôtel Métropole, under the presidency of Captain Sir James Anderson.

MANCHESTER, 4th June, 1891.

Decoration by Machinery.—A notable exhibit is on view at the Arts and Crafts Exhibition, of a number of articles decorated by machinery. Glass, metal, or wood can be decorated by the system, which is similar to calico printing in so far as the use of copper rollers engraved with a pattern is concerned. The article to be treated can be passed through the rollers at a quick speed, and a door is shown which, after being fully constructed, was printed with a grain pattern on both sides simultaneously. The exhibit is an interesting one, and is shown by the Rossendale Glass and Wood Decorating Company, of this city.

Reduction of Working Hours.—By arrangement with the employers, the working hours of workmen in the printing trades have been reduced by 2½ hours. A few firms have not granted the reduction, but it applies to most firms in the trade, and has come into operation this week.

Fire Brigade Stables.—An improved arrangement has been invented by the Chief of the Manchester Fire Brigade, Mr. Tozer, which consists of a novel form of shutter working in a slide and having a chain attached to it, the other end of which has a weight fastened to it. The door is held in position by a pin, by withdrawing which the door is drawn up by the weight. A buffer is fixed to take the shock of the ascending door. The horses stand facing the door, so as to be readily harnessed, and the harness, which is specially constructed, can be placed in position by two movements. The time necessary for turning out is much shortened by this appliance.

Sewage Disposal.—An important step is proposed by the Conservancy Committee of the Salford Corporation. In view of the pollution of the Irwell by liquid refuse emitted from the works in the borough, they propose that settling tanks, if provided by the manufacturers, should be periodically emptied of sludge at a fixed charge per ton. This step, if approved by the council, will mark an important departure in municipal practice.

The Iron Trade.—The speculative movements in pig iron have quite unsettled business in this district, and although prices for actual deliveries have not varied to the same extent, the prevalent disbelief in any continuance of high rates prevents new business being effected. There are signs that the market is generally easier than it was, although users are still absorbing a large weight weekly. There is, however, a slackening in some quarters which is significant. Builders' ironwork is in good demand, and pig iron for this class of work is being consumed largely. Bar iron remains at about £5 17s. 6d. per ton, but neither in common or marked brands is there a satisfactory business. Steel plates for boilers are in steady demand, and prices are well maintained. In copper the advance in prices has, as yet, produced no effect upon business, the movement in Chili bar prices being looked upon as purely speculative.

The Linen and Jute Trades.—There has been a better feeling this week, both in the jute and linen branches, and sales have increased somewhat. The advances in bleached goods have alarmed some buyers, who are much more inclined to operate now that they perceive the tendency of the market. Yarns have been in better demand, both in home and Continental spins. Buyers now find that their requirements can be promptly met at Lille for large quantities, and the result of this has been that many English and Irish firms now despatch representatives regularly to the French centre. There has been a substantial advance in all classes of yarns, both tows and lines, of late, and heavy purchases have been made. Linens for the home trade meet with a steady sale. Damasks are rather quiet, but coarser makes have for some time been in brisk request. Kirkcaldy has been able to keep up sales in this district, and heavy makes of Forfar goods generally have been well inquired for. There has not been so much demand from retailers, but a better inquiry is anticipated before long, and merchants are disposed to place orders with greater freedom. For shipment there is not much business with South America, but orders for the United States are satisfactory, and the tone is one of greater confidence as to the future. The Australian section of the trade is also in a satisfactory condition, but for Central America and the West Indies there might be more business. The Continental trade is fairly well maintained, considering the keenness of the competition in the German, French, Austrian, and Belgian markets. There is a steady French trade, and it is evident that Lille has not made much progress of late.

GLASGOW, 4th June, 1891.

Electric Light in Glasgow.—The supply of electricity by meter was commenced in Glasgow about two years ago by a limited company (Messrs. Muir, Mavor, & Coulson), and generating plant for supplying current at low tension as well as at high tension was put down gradually. The plant at present is of a capacity of over 500 i.h.p. From this plant the Municipal Buildings, the General Post Office, the Exchange, and other buildings, public and private, are lighted. The firm applied to the Board of Trade for a provisional order upwards of twelve months ago, but, the Corporation opposing, this was not granted, and, instead, the application of the municipal authorities for a provisional order was granted. The time allowed for the commencement of operations under this provisional order is now drawing to a close, and the Corporation are engaged in considering the expediency of carrying out the work on account of and at the risk of the city, or of contracting with some company to relieve them of their obligations under their provisional order. The company already carrying on the work have offered to sell their plant to the Corporation and to lease it from them for seven years, undertaking to pay interest for the capital sums expended by the Corporation upon the undertaking, and to pay to the Corporation any profits earned by the company beyond a specific amount.

Minerals.—It is difficult to say decisively whether a reaction in the pig-iron market has set in. Last week the price advanced 5s. per ton, while the beginning of this week found the market in a state of collapse, and the price falling rapidly. On the 2nd inst. the fall from the price of the previous day was 6s. per ton. Although this is undoubtedly an indication of the state of the market, the quantity which has changed hands so far is insignificant. It has now transpired that the chief share in the recent manipulations, by which, for a time, the price was forced upwards, was a well-known local operator. Small lots of pig iron for forward delivery are being sold at much less than current rates. One lot, of 500 tons, has been sold for delivery in December at 45s. 6d.—The increase in coal shipments was not so considerable last week as formerly, but the aggregate increase this year amounts to 119,475 tons.

Large Bridge for India.—The Indian Government has contracted with Messrs. P. & W. McLellan to supply a bridge, 1,800ft. long, for the Kistnali River. The steel for the bridge, which amounts to 3,500 tons, has been ordered from the Steel Company of Scotland.

Scottish Railways.—The Railway Bills promoted by the North British Railway, and postponed owing to the death of Mr. John Walker, are again before the Committee.

Shipbuilding.—The proposed reduction of wages in the Clyde shipyards has been postponed until the decision of the adjourned meeting of the Employers' Society is known. It is understood that the employers are not unanimous in the matter, and that considerable difficulty has been experienced in arriving at a decision.

(From our own Correspondents.)

LIVERPOOL, 3rd June, 1891.

The Vyrnwy Water Supply.—The temporary pipe line across the bed of the Mersey near Fidler's Ferry was very successfully laid on the 31st ult., and reflects great credit upon Mr. Deacon for the skilful manner in which such a difficult operation was planned and carried out. The pipe line is 800ft. in length, and consists of 50 lengths of steel pipes 12in. in diameter, jointed with flexible joints, so that the pipe may adapt itself to the undulations of the bed of the river. They were first laid in a trench on the Lancashire side of the river, each pipe resting on a wooden block at the joint, the block resting upon longitudinal launch ways. Wire cables were fixed to the pipes, and these were coupled to the steam winches and horses on the other side of the river; at a given signal, the pipes were drawn across the river, being guided in their course by a number of boats kept under control by wire cables. The pipes were laid slightly zigzag on the shore so as to give the necessary "slack" to be taken up by the curve of the bed of the river. The Norton Tower was successfully filled a few weeks ago, and the pipes charged to the Cheshire bank of the Mersey. The permanent works under the Mersey are now progressing satisfactorily, 50 rings of the segmental plates having been fixed, and it is expected that the tunnel will now proceed at the rate of 6ft. per day.

SHEFFIELD, 3rd June, 1891.

The Iron Trade.—The recent slight advance in pig iron has given more confidence to the trade generally, and all tenders for contracts are based upon the higher value of raw material. In railway work there continues to be a fair business. Tyres and axles maintain their price of £10 to £12 per ton. Waggon builders are fairly supplied with work, mainly on account of English railways. The Tubular Waggon Company are trying to introduce their long bogie cars. The chilled wheels are very well constructed, but in

Digitized by Google

other respects the car may require some alterations to make it suitable for English traffic. Messrs. Kitson, of Leeds, are turning out some fine locomotives for the Midland Railway Company, and, amongst other improvements, the inside cylinders are cast in one piece. The heavy forging hammers and presses are rather slack, as there is very little marine work in course of construction. Armour plate mills are well supplied with work. Messrs. Vickers are progressing well with their guns, and the smaller sizes are rapidly being completed.

COAL.—Fuel continues in brisk demand. The large quantity of coal shipped to the Continent helps to maintain the price.

REDUCTION IN WORKING HOURS.—Messrs. Hadfield's Steel Foundry Company have voluntarily reduced the hours of their employés to fifty-one per week. No change is to be made in the rate of payment.

ELECTRIC LIGHTING.—The price of gas at Barnsley being 3s. 4d. per 1,000ft., the Corporation decided to try electric lighting, and had practically accepted a tender for lighting some portions of the borough at £25,000. The Board of Trade, however, now insist upon underground wires, after twice giving their sanction for overhead wires. As this would nearly double the cost, the scheme remains in abeyance. Sheffield is to have a brick culvert under the main streets, in which all pipes and wires are to be placed. Inconvenience to traffic, and damage to road surface generally, will thus be avoided.

BIRMINGHAM, 3RD JUNE, 1891.

GENERAL TRADE.—Business in this district is not brisk, and the iron trade is inactive. The price of coal has fallen a little, and the price of pig iron has been reduced. Cinder pig is being quoted at about 37s. 6d. per ton, though such a price is regarded as unremunerative. Bar iron has scarcely changed, £6 per ton being quoted for common, and £6 5s. and £6 15s. for "Cable" and "Best Cable" qualities respectively. Cable makers are fairly supplied with orders for the present. Rivet and bolt makers are very busy. Some large inquiries for anchors for abroad have been circulated amongst the Cradley and Old Hill makers, and a Tipton firm recently secured an important contract for anchor stocks for the Admiralty. It is reported that the anchors for the same order are to be made of steel by Scotch makers. Many of the Staffordshire makers are now sending out large numbers of stockless anchors with heads of cast steel. The public chain and anchor proving houses are very well employed. The Earl of Dudley's Round Oak Works, Ld., is now in working order, and the preparations for extensions are being pushed forward. The New British Iron Company also contemplate the erection of large mills for the production of blooms, billets, and heavy sections of iron and steel at their Congreaves Works.

LEICESTER, 3RD JUNE, 1891.

WOOL SPINNING AND YARN TRADES.—The local wool market shows little change, but it is in a somewhat unsettled state. Sales are slow and for small amounts, as buyers are holding off as much as possible until the new clip is on the market. Opinions differ as to the prices which it will fetch. Prices, as a rule, remain firm, and stocks are not very heavy. Short fleeces of choice quality sell fairly well, and so do skin wools. Spinners are all fairly well employed, and are making rather larger deliveries. Buyers are very cautious in placing orders, and spinners press for an advance in prices which it is still very difficult to get. Lambswool yarns are selling steadily, but cashmeres and cottons sell very slowly.

HOSIERY TRADE.—Business shows signs of improvement, but the trade doing is very unevenly distributed, some firms being very busy whilst others are very quiet. The weather has considerably affected this industry, and repeat orders for light goods are few and small.

SWANSEA, 3RD JUNE, 1891.

NEW LINE.—Rapid progress is being made with the Rhymney Railway Company's extension in the Aber Valley. The new line, a single one, will join the main line at Aber Box and run along the left side of the valley for about 3½ miles. There will be two stations, one at Aber village and another at Park Newydd, which will be the terminus. It is anticipated that this extension will cost about £50,000. The sinking of three collieries is already contemplated as soon as the line is sufficiently advanced to allow of the transport of machinery.

THE SWANSEA HEMATITE IRON COMPANY.—These works were started again on the the 27th ult., the majority of the men having accepted the 10 per cent. reduction in wages.

NEW TINPLATE WORKS.—Notwithstanding the adverse conditions that have compelled the masters engaged in the manufacture of tinplates to decide on a whole month's stoppage, there seems to be no lack of confidence in the future of the trade. At a general meeting of the shareholders of the Briton Ferry Steelworks just held, it was unanimously carried that a new tinplate works, to consist of four mills, in connection with the steel works be erected forthwith. The location of the new works will be between the Villiers Tinplate Works and the Briton Ferry Blast Furnaces.

THE TAFF VALE RAILWAY.—The report of Messrs. Swarbrick & Tomlinson, advisers to the investigation committee, gives some interesting figures as to the cost of working various railways in Great Britain. The cost of locomotive power per train mile for the past three years has been 17·26d. on the Taff, compared with 8·22d. on the Midland, 8·15d. on the Great Northern, 7·17d. on the Caledonian, and 6·68d. on the Rhymney. Carriage and waggon repairs have cost also, for the past three years, 7·57d. per train mile on the Taff, as against 2·51d. on the Midland, 2·79d. on the Great Northern, 2·29d. on the Caledonian, and 4·21d. on the Rhymney. The committee estimate that by the appointment of a competent and experienced traffic manager from £40,000 to £50,000 per annum may be saved.

CARDIFF, 3RD JUNE, 1891.

IRON AND STEEL.—The condition of the steel trade is anything but cheerful, and as Bessemer bars will not be required in the whole district during July, owing to the stoppage of nearly all the tinplate works during July, makers are turning their attention to rails. Orders are, however, very scarce, as buyers anticipate a further reduction, which, on the other hand, it is impossible for manufacturers to concede, in view of the high prices of iron ore and fuel. Steel rails, heavy sections, are quoted at £4 10s. to £4 15s. Notwithstanding the advance in the value of Scotch and hematite warrants, consumers can still obtain their requirements in pig iron at prices which ruled during the spring. Rubio, first quality, is quoted at 13s. 3d. c.i.f. Cardiff and Newport, for 50 per cent. iron; second quality, 12s. 6d. to 12s. 9d.

COAL AND COKE.—Steam coal is quoted at:—No. 1 quality, 15s. 3d. to 15s. 9d.; No. 2 quality, 14s. 6d. to 15s.; No. 3 quality, 13s. 6d. to 14s. 3d.; No. 4 quality, 13s. to 13s. 3d.; small steam 7s. to 7s. 3d. The demand for coke is limited, and at Rhymney some of the coke ovens will be put out on account of the blowing out of another blast furnace. Prices for foundry are 21s. 6d. to 22s. 6d.; special foundry, 24s. to 25s.; and furnace, 19s. to 19s. 6d.

THE BRITISH ASSOCIATION.—The British Association will hold its sixty-first meeting in this town from August 19th to the 26th. A local committee has been formed, and every facility will be given for the various meetings, as well as for visits to mines and docks which have contributed so largely to the rapid growth of Cardiff.

BARROW-IN-FURNESS, 3RD JUNE, 1891.

HEMATITE.—Business in hematite pig iron has been done only on a small scale this week, and the transactions in hematite warrants, as well as in makers' iron, show a small trade. Warrants have been further cleared, although prices have kept up to 53s. 3d. per ton net cash, while makers have been asking 53s. 6d. net f.o.b. for parcels of mixed numbers of Bessemer iron. The Moss Bay Iron and Steel Company have put in blast two of the four furnaces which have been standing idle for so long a time, and Messrs. Cammell & Co. have commenced the erection of another furnace, which is to be engaged mainly on speigeleisen. There are now 41 furnaces in blast, compared with 46 in the corresponding week of last year. Stocks have this week been reduced 3,439 tons, and now stand at 139,543 tons, of which only 12,127 tons are stocked in Furness.

APPOINTMENT.—Mr. David Evans, general manager of the Barrow Steel Company, has been appointed to a similar post with Messrs. Bolckow, Vaughan, & Co., Middlesbrough. Mr. Evans during his few years' stay in Barrow has achieved a marked success in resuscitating the Barrow Steel Company. He cleared off an outstanding liability of £100,000, paid off back preferences, and declared last year 2½ per cent. on the ordinary stock.

MIDDLESBROUGH, 3RD JUNE, 1891.

PIG IRON.—The iron market was very weak yesterday, caused by the fall in the prices of Scotch warrants of 6s. on the best price quoted on the 1st inst., and business is practically at a standstill. Of course no one expects that there will be as rapid a drop in prices of Cleveland as in Scotch iron, for while it only advanced 5s. 6d. per ton, Scotch went up 18s. Both buyers and sellers are reluctant to operate, the former because they look for a rapid fall in prices, while sellers think that prices will go up again. Much harm is done by this continued speculation, and the conclusion of the present artificial state of affairs is anxiously awaited. Middlesbrough warrants have declined about 1s. since last week, and can now be had at 40s. 10½d. cash, buyers offering 40s. 9d. Makers' No. 3 G.M.B. has fallen 6d. per ton, and is quoted at 40s. 6d. There is no business for forward delivery. No. 4 foundry iron is 39s., and grey forge 38s. per ton. Mixed numbers of local hematite are offered at 51s. 6d. per ton. It is calculated that the stocks in the district have decreased some thousands of tons, though there is increase of 7,000 tons in the public warrant stores.

MANUFACTURED IRON AND STEEL.—The finished iron and steel industries are in a depressed condition. The manufacturers are worse off than ever, for, while they have to pay more for their pig iron, they have to accept lower prices for their productions. Common bars are £5 12s. 6d.; best bars, £6 2s. 6d.; iron ship plates, £5 10s.; steel ship plates, £6 10s.; iron ship angles, £5 5s.; steel ship angles, £5 15s., all less 2½ per cent. and f.o.t. Heavy steel rails are £4 10s. per ton net.

COKE.—Blast furnace coke of average quality can be had at 13s. per ton, delivered at works.

SHIPMENTS.—The shipments of pig iron for May are the best this year, amounting to 82,363 tons, as against 79,783 tons in April, and 80,251 tons in May last year. Of this quantity 30,931 tons have gone to Scotland, 8,540 tons to England and Wales, and 42,892 tons foreign. The comparative shipments for the five months January to May for the past three years are:—1891, 343,078 tons; 1890, 299,781 tons; 1889, 405,884 tons. The shipments of manufactured iron and steel for May amounted to 44,149 tons, of which 8,106 tons went coastwise, and 36,043 tons foreign. The chief customers were:—India, with some 16,000 tons; Cape Colony, 3,082 tons; and Egypt, 3,606 tons.

IRONMASTERS' RETURNS.—The returns of the Cleveland Ironmasters' Association for the month of May were issued to-day, and proved to be fairly satisfactory. There were 89 furnaces in blast, against 91 during the previous month. Of these, 53 were on Cleveland pig and 36 on hematite. The make of Cleveland iron for the month was 123,906 tons, an increase of 3,691 tons on April. Of hematite pig 92,775 tons were produced, a decrease of 9,077 tons. The total make was 216,681 tons, a decrease of 5,386 tons on April. Makers' stocks are 139,037 tons, a decrease of 10,770 tons. In makers' stores there are 1,820 tons, a decrease of 656 tons. In the public stores there are 126,936 tons, an increase of 8,020 tons. The total stocks are 267,793 tons, a decrease of 3,406 tons for the month as compared with April.

NEWCASTLE, 3RD JUNE, 1891.

THE IRON TRADE.—In the local iron trade business is flat, though one or two manufacturers of specialties in finished iron, among whom may be named Messrs. Raine & Co., of Winlaton, are kept busy, and are well supplied with forward orders. It is reported that the blast furnaces at Low Walker, which were blown out a few weeks ago, will again be put in operation before the autumn. Galvanising works are beginning to show a falling off of business, and a lessened trade is also being experienced in the forges. Messrs. John Spencer & Sons' forge at Ouseburn is, however, an exception, and in this instance there still appears to be a large amount of work in progress. Foundries are still generally pretty active, the establishments of Messrs. Hawthorn, Leslie, & Co., Forth Banks; Messrs. Abbot & Co., Gateshead; and Messrs. Chapman & Carverhill, Elswick, being very well supplied with work. The decline of business in some of the larger industries has adversely affected rivet works and chain works.

THE COAL TRADE.—In the steam coal trade business is still active, but for gas and manufacturing coals the demand has decreased, and in respect of household qualities there is decidedly less inquiry. The shipments of coals and coke at Tyne Dock during the week ending the 30th ult. amounted to 120,693 tons, being an increase as compared with the shipments for the corresponding week last year of 23,112 tons.

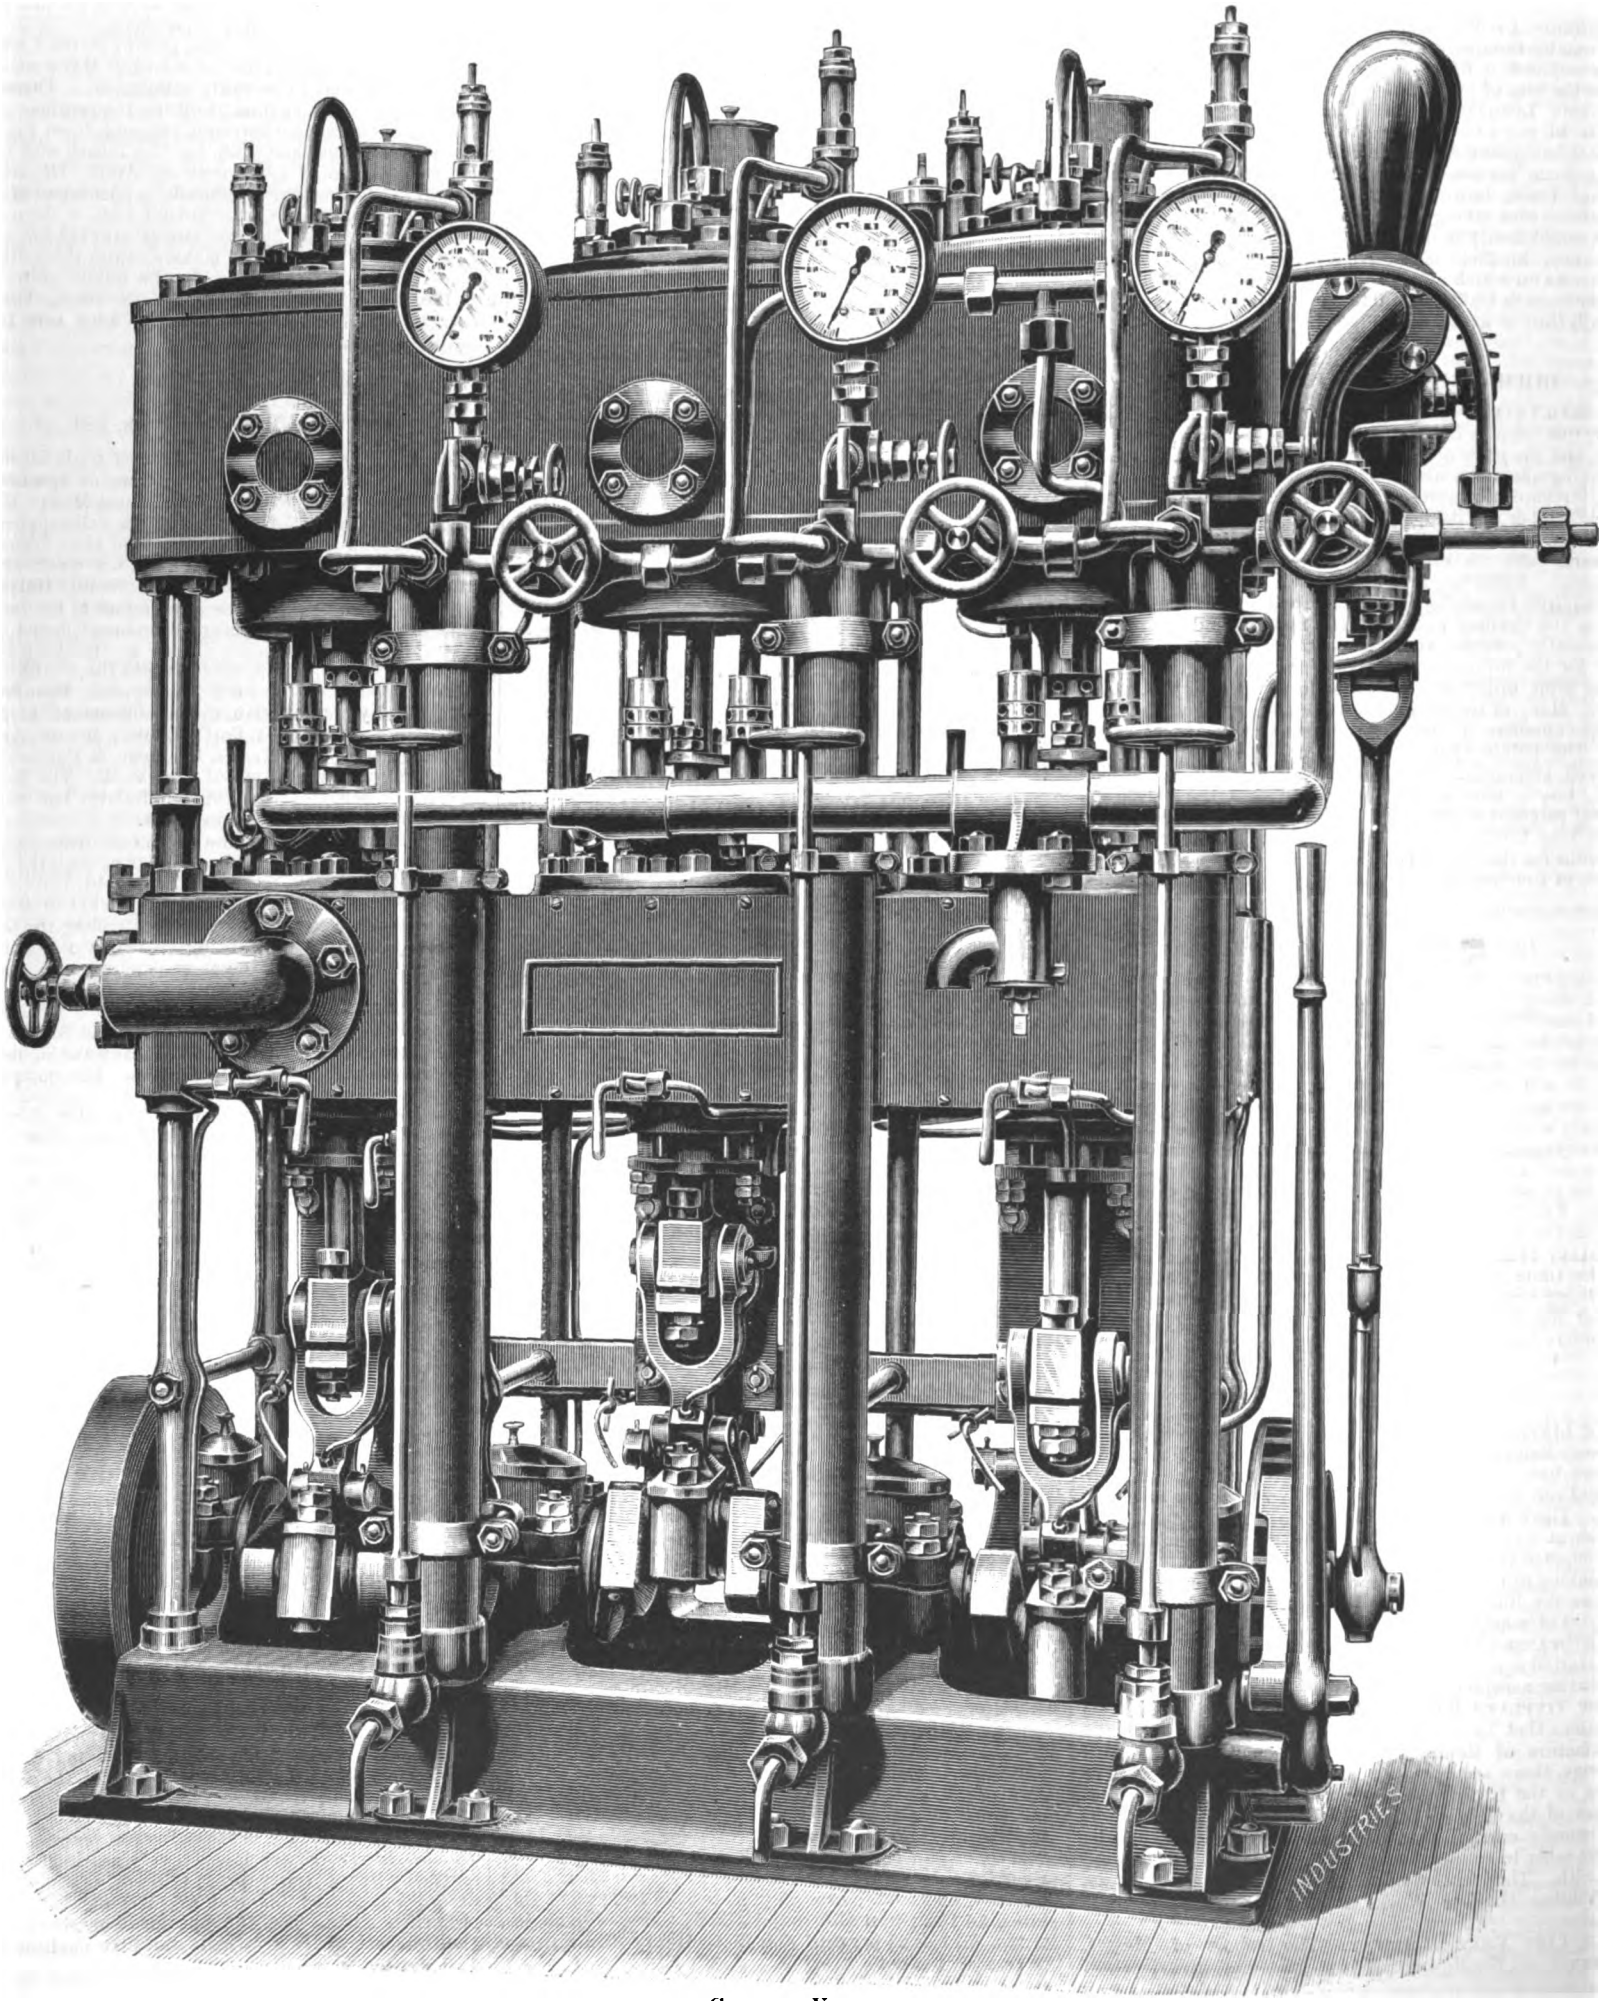
THE IRWELL RUBBER COMPANY.—This firm of Manchester manufacturers have opened a depôt for the sale of their productions at 7, Dean Street, Newcastle, under the superintendence of Mr. Thos. Beynon. The company are extensive producers of rubber goods for engineering purposes, and the opening of a branch in this district can hardly fail to effect a considerable extension of their business.

STEEL WORKS.—Messrs. Ibbotson Bros., the well-known Sheffield firm of steel manufacturers, are actively preparing for an early commencement of productive operations at the Gateshead Steel Works, which came into their possession several months ago. Much difficulty has been found in making the place ready for the special branches of manufacture which the firm intends to carry on there. The final arrangements, however, for commencing steel production are now in progress.

THE "STOCKPORT" GAS ENGINE.—The agency for the sale of the "Stockport" gas engine is shortly to be removed from Cloth Market to more commodious premises in Collingwood Street.

DUNDEE, 3RD JUNE, 1891.

THE JUTE AND FLAX TRADES.—The linen trade is quiet, but steady. Buyers of flax appear to be well supplied, and there is little business. Sellers' stocks being small, however, prices are firm. A moderate business is passing in flax and tow yarns at recent rates. For cloth the demand is fairly good, and foreign buying is rather better. In jute there has been little doing. Advices from Calcutta report a stronger market for baled jute. The prospects of the new crop are reported to be more favourable. There is a slow demand for jute yarns, and while prices are unaltered sellers cannot find buyers without granting concessions. Jute goods are in quieter demand, and the New York market is weaker, burlaps 40in. 10½oz. being quoted at 4 1/16c. per yard, and light weights at 4⅜c.



THE "DUNDEE ADVERTISER."—The proprietors of the *Dundee Advertiser* have issued a very neat little pamphlet, entitled "How a Newspaper is Printed," in which is given a description of the different departments in the *Dundee Advertiser* office. The pamphlet also contains a history of the *Dundee Advertiser*, which was first published on the 16th January, 1801.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 5TH JUNE, 1891.

THE LONDON POLYTECHNICS.

THE study of place names is as curious as it is interesting and instructive, as from it we often obtain a great deal of information regarding the place itself. The study of descriptive names is not less curious, but often confusing and perplexing, for very often the names remain when the things themselves have completely changed their nature. The name "Polytechnic" is one which is used in many senses, but which yet has a very definite original meaning. Possibly it was first applied to an educational institution when Napoleon the First founded the École Polytechnique in Paris. That institution, curiously enough, is not, and never has been, a polytechnic in the proper sense of that term, although it was intended originally to be what its name implied. At present it is a high-class scientific school, but almost entirely concerns itself with the theoretical side of the subjects taught, and is used chiefly for preparing candidates for different departments of the military service. Belonging to the Government, but in a different department, there are the École des Ponts et Chaussées and the École des Mines, to which a few of the best students of the École Polytechnique are drafted, so that, in a sense, the latter institution is only a preparatory one for those in which the technical applications are taught. In Germany, on the other hand, the polytechnics are technical high schools, and, educationally, are on the same plane as the professional faculties of the universities, and, in fact, it has been suggested that they should become so in name, as much as they are practically so at present.

In this country, however, the name polytechnic has never stood in a very high position. It has been very often applied to shops or retail warehouses in which were sold a variety of things, chiefly of an industrial or mechanical nature. In London the well-known Regent Street Institution, in which were shown all the wonders of the day, seems destined to bequeath its name to a very numerous progeny, which, however, do not bear a very striking resemblance to the parent. For some years, through the generosity of Mr. Quinton Hogg, the old Polytechnic has been used as an institution for the benefit of young men and women, and in it there was, no doubt, a useful educational element, but there was also much that was recreative, and, to a very considerable extent, religious and moral. There cannot be the slightest doubt that institutions of this kind are of the greatest possible service in London, but what we wish to point out at the moment is the peculiarly British way of giving them names. The original institution was a show, and during what may be called the transition period this element largely prevailed, though others of a recreative and educational nature were afterwards added. A movement is now in progress for the extension and development of such institutions all over London. No doubt the educational part of the programme will be placed upon a proper basis, but the other parts will not disappear, and rightly so, for we consider them very important in their way. A German, however, coming to London and visiting such institutions, will find much to amaze and possibly amuse him, for, instead of high-class scientific study, he will find combinations of elementary and secondary schools, gymnasiums, and recreation rooms.

The scheme for the erection and extension of the so-called "Polytechnics" is due to an Act of Parliament passed about eight years ago, at the instance of Professor Bryce, to carry out the recommendation of the Commissioners on Technical Education, that "steps be taken to accelerate the application of ancient endowments, under amended schemes, to secondary and technical education." The Act provided for the diversion of a great part of the funds of the City, which had hitherto been, to a large extent, wasted or misapplied, to some purpose which would benefit the poorer inhabitants of London. The work has been done under the superintendence of the Charity Commissioners, and the scheme may now be considered to be fairly inaugurated. The central governing body has been elected, and has held a preliminary meeting, and arrangements have been made for the ultimate establishment of institutes in all parts of London—North, South, East, West, and Centre. Existing institutions are to be utilised and extended, and, of course, endowed. Among those which will benefit in this way are the Regent Street Polytechnic, the People's Palace, the City of London College, and the Birkbeck Institute. The two latter, together with a new institute to be established in Clerkenwell, are to be grouped together under the title of the City Polytechnic, while the needs of the Southern district are to be supplied by institutes at New Cross, Borough Road, and Battersea. Of these the New Cross Institute will be maintained entirely by the Goldsmiths' Company, and therefore it does not fall directly under the scheme of the Charity Commissioners, but it has been taken into account by them in making their arrangements. The Commissioners have wisely endeavoured to encourage local effort by offering an endowment equal to the amount of the local contributions, and in some cases the response has been very remarkable. In Battersea, for instance, over £50,000 has been raised locally. The promoters, therefore, feel justified in going on with the scheme, and have decided on the plans to be adopted. It was at one time proposed to acquire the Albert Palace, but the expense was too great, and moreover the existing buildings were not specially suitable to the requirements. It has been now decided, however, to erect new ones at a cost of £40,000.

The New Cross Institute will be housed in the buildings formerly occupied by the Royal Naval School, while at Borough Road, the British and Foreign Training College and the Morley Memorial College will be utilised. The Institutes for the North and the West have not been decided upon, as the necessary funds have not been raised, although they form part of the general plan. There can be no doubt that these institutes, if properly organised and managed, may exercise a most important educational and social influence in London. It is, therefore, to be hoped that they will be fortunate enough to secure governors who will have their hearts in the work, and who will have sufficient knowledge of the requirements of education to enable them to distinguish real education from mere cramming of information. For some years the institutes should be allowed to grow gradually, and be designed so that they may be extended. Their nature is so different

Digitized by Google

from that of any institutions which have been hitherto carried out that the whole question cannot be considered to be beyond the experimental stage, and it would be a great mistake to make them all of exactly the same type. The science and art classes will no doubt be in connection with South Kensington, and we hope that the proposal which was made some time ago by the Council of the National Association for the Promotion of Technical Education will be adopted. We trust that, instead of individual grants on account of students, the Science and Art Department will be willing to pay an annual sum to the central governing body, the amount of which will depend more on the average attendance and the general nature of the work done than on the results of individual examinations. It has been remarked that the constitution of the first Board is disappointing, and that it seems constituted rather with a view to the management of the estates than to the advancement of education, and that results will be measured in too commercial a spirit. We trust, however, that it will rise to the occasion, and that it will co-ordinate its work with that of the University Extension Society. We should thus have in London an organisation which would be a popular University of London, and which would give opportunities to the most promising of its students to prepare themselves for the work of the real University of London.

SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

According to a programme recently issued of the proceedings at the meeting of the Congress which is to be held in London from August 10th to 17th next, the Congress has previously been held in Brussels, Paris, Turin, Geneva, The Hague, and Vienna. The Permanent International Committe, appointed in Vienna, resolved, on the invitations of the Sanitary Institute and the Society of Medical Officers of Health, that the Seventh Congress of the series should be held in London in 1891. The Seventh Congress will be inaugurated on August 10th by a general meeting in St. James's Hall. H.R.H. the Prince of Wales, the President of the Congress, will preside at the opening meeting, and will take the chair at 3.30 p.m. The Congress is organised in two divisions and ten sections. The meetings of the sections will be held on August 11th, 12th, 13th, 14th, from 10 a.m. to 2 p.m. Division I.—Hygiene. Section I. (Preventive Medicine) will meet in the rooms of the Society of Antiquaries, Burlington House. Section II. (Bacteriology) will meet in the rooms of the Royal Society, Burlington House. Section III. (The Relations of the Diseases of Animals to those of Man) will meet in the rooms of the Geological Society, Burlington House. Section IV. (Infancy, Childhood, and School Life) will meet in the theatre of the University of London, Burlington Gardens. Section V. (Chemistry and Physics in Relation to Hygiene) will meet in the rooms of the Chemical Society, Burlington House. Section VI. (Architecture in Relation to Hygiene) will meet in the West Examination Hall in the University of London, Burlington Gardens. Section VII. (Engineering in Relation to Hygiene) will meet in the East Examination Hall in the University of London, Burlington Gardens. Section VIII. (Naval and Military Hygiene) will meet in the rooms of the Linnæan Society, Burlington House. Section IX. (State Hygiene) will meet in the rooms of the Astronomical Society, Burlington House. Division II. (Demography) will meet in the theatre of the Royal School of Mines, Jermyn Street. Excursions will be made on August 15th, and the closing meeting of the Congress will be held on August 17th at 11 a.m., in the theatre of the University of London. The aim of the Congress is to stimulate public interest in the progress of Hygiene and Demography, by which latter term is understood the study of the life conditions of communities from statistical points of view, and to afford persons interested in these subjects an opportunity of meeting and of elucidating questions connected therewith by conference and debate. The Governments of all countries, municipalities, county councils, and other local administrations, public health authorities, universities, colleges, and all societies which are occupied in the study of the sciences more or less immediately connected with hygiene, are invited to co-operate and appoint delegates to represent them at the Congress. Up to the 1st ult., 508 delegates have been appointed by 149 bodies. All delegates from the bodies above mentioned, and all persons who are interested in the work of the Congress, are eligible to become members thereof. Tickets of admission to the Congress may be obtained through the post by letters addressed to 20, Hanover Square, W., and containing a remittance of £1—apart from any subscription which a member may contribute towards the Congress fund—together with the title and address of the applicant given in full. An Indian Committee has been formed with the object of making known the aims and work of the Congress in her Majesty's Eastern possessions and dependencies. Every endeavour will be made to make the visit of the Congress pleasant and instructive to the members, and to enable them to see to advantage whatever England has to show which is of interest from the point of view of sanitation, science, art, and archæology.

THE COINAGE DURING THE YEAR 1890.

According to the twenty-first annual report recently issued by the Deputy-Master of the Mint, Sir C. W. Fremantle, there was a very large production of coinage during the year 1890, which is the more remarkable as the production in the previous year had been much in excess of the average. The value of the gold coinage issued during the past year was £7,680,156, of the silver coinage £1,694,688, and of the bronze coinage £90,285. The average value of the gold coinage during the preceding ten years was under two millions and a quarter, so that the amount coined during the year 1890 is extraordinarily large. The amount of light gold withdrawn from circulation in consequence of the Coinage Act of 1889 amounted to £2,463,148, at a cost of £51,299. The cost of withdrawing the light gold coins of former reigns was about 5d. per pound sterling. The total gold coinage of the Australian mints during the past year amounted to £5,924,000. About half of the total issues of the Australian branch mints are on the average sent to England. Silver coins of the total nominal value of £1,694,688 were issued during the past year. The total value of the silver coinage of the new design is £5,256,000, of which more than one-half is supposed to be in circulation in this country. Forty-two millions of the smaller pieces, shillings, sixpences, and threepences, were added to the circulation, as compared with 14 millions of the larger. As the average price of silver in 1890 exceeded that of 1889 by $5\frac{7}{8}$d. per ounce, there was a seignorage of $35\frac{1}{2}$ per cent. as compared with 54 per cent. in the previous year. The total amount of bronze money issued was £90,285, which exceeds that of the large issue of 1889 by £24,000. The number of bronze coins issued was nearly 29 millions, the weight of which was 213 tons. The net profit of the Mint has exceeded that of every previous year except that of 1889, when the low value of silver allowed of a large profit on the silver coinage. During the past year there were melted in the melting-house 192 tons of gold, 388 tons of silver, and 74 tons of copper, besides $4\frac{1}{2}$ tons granulated for alloy. Eighty-eight million coins were struck in the coining press-room, and these were of 25 different denominations; 17,500,000 of these coins were rejected for various reasons. Thirty-six thousand and nine assays were made during the year, and investigations were carried out for the purpose of obtaining such alloys as would preserve their homogeneity during the process of cooling.

THE ROYAL COMMISSION ON THE LABOUR QUESTION.

At a meeting of the Royal Commission held on the 28th ult., under the presidency of the Marquis of Hartington, a decision was arrived at as to the method of procedure. The report of the Committee of Procedure is as follows:—

1. That for the purpose of taking evidence and collecting information, the Royal Commission be divided into three Committees.

2. That each of these Committees should institute an inquiry into the facts concerning the condition of certain groups of trades, leaving questions of principle to be treated by the Commission as a whole.

3. That for this purpose the following division of trades should be adopted, the division being provisional and non-exhaustive:—Group (a.) The mining, iron, engineering, hardware, shipbuilding, and cognate trades. Group (b.) Transport and agriculture: the term transport including shipping, canals, docks, railways, and tramways. Group (c.) Textile, clothing, chemical, building, and miscellaneous trades.

4. That it shall be in the power of members of one Committee to attend the meetings, and examine and cross-examine witnesses at meetings of other Committees; and that each Committee should report to the Commission the evidence taken, or a summary of such evidence, if they think fit.

5. That the following syllabus be submitted as a convenient summary of the subjects to be inquired into by the Committees:—

Trade Differences between Employers and Employed.

1. Their causes. 2. Their development, organisation, and conduct. 3. Their cost. 4. Their prevention or settlement.

1. Their Causes.

A. Wages:—1. How fixed. 2. How calculated: a. By piece work. b. By day work. c. By task work. 3. How paid: a. Direct, by employer, or by sub-contractor. b. Weekly, fortnightly, or at other periods. c. Increased by bonus, or reduced by stoppages. d. Truck or payment in kind. e. House, land, or other allowances. 4. Fluctuations of wages: a. How brought about. b. How adjusted. 5. Differences of wages in different establishments and localities. 6. Existence and effect of: a. Pensions. b. Deferred pay. c. Sick insurance. d. Accident insurance. 7. Notice required for the termination of wage contracts.

B. Hours of labour and continuity of employment:—1. Normal hours of work. 2. Overtime, and how remunerated. 3. Night shifts, and how remunerated. 4. Short time, season work, or other irregularity of employment. 5. Sunday and holiday labour, how arranged and paid for. 6. Duration of day's work, and week's work, and how regulated.

C. Subdivision, distribution, and classification of work, as between different trades, individuals, men, women, or children, whether half-timers or not, factories, workshops, or homes.

D. Apprenticeships.

E. Introduction of machinery.

F. Supply and quality of the machinery and materials of production or transport.

G. Safety of employment, provisioning of ships, lighting, sanitation, and inspection of workplaces.

H. Discharge for belonging to a trade union.

I. Refusal to work with non-unionists.

J. Discharge of representative delegates and use of black list.

K. Employment of foreigners.

L. Obnoxious officials.

M. Sympathetic strikes.

N. Other causes of dispute.

2. Their Development, Organisation, and Conduct.

A. Trade associations or combinations of employers or of employed, whether permanent in character or temporary, occasional, or for special dispute purposes, their trade rules, benefits, and policy. B. Strikes and lock-outs, picketing, blacklisting, and other methods of influencing persons concerned or not directly concerned in the dispute. C. Importation of new or foreign labour, whether under contract or otherwise.

3. Their Cost.

A. Economic result of strikes and lock-outs to workers, to employers, and to the community at large.

4. Their Prevention or Settlement.

A. Conciliation by joint committees or otherwise. B. Mediation. C. Arbitration, voluntary or compulsory. D. Sliding scales. E. Profit sharing. F. Industrial partnerships. G. Co-operation.

6. We have instructed the secretaries to prepare a schedule of questions founded upon the syllabus, and we suggest that it should be sent to the different unions of employers and of employed, and other representative bodies or persons.

The subjects which are to be considered by the Commission will be divided into three sets of questions, the first to be sent to the unions of employers, the second to unions of employed, and the third to other representative bodies or persons. The first division will be considered by the Commission; whilst the other two divisions will be referred to Committees. It is expected that the Committee of Procedure will complete their work during this week, and that the Commission will begin to take evidence next week.

THE LATE SIR JOHN HAWKSHAW.

We regret to record the death of Sir John Hawkshaw, F.R.S., who died on the 2nd inst. at his residence, Belgrave Mansions, London, in his 81st year. He was born at Leeds, and at an early age was placed as a pupil with Mr. Charles Fowler, who was engaged in constructing turnpike roads in Yorkshire. He afterwards became an assistant to Mr. Alexander Nimmo, who was employed to design a scheme of railways between Manchester, Leeds, and the Humber. When only 20 years of age, he became manager of the Bolivar Copper Mines in Venezuela, and occupied that post for three years. Whilst he was in South America he acquired an intimate knowledge of the country and of its people, and a few years afterwards wrote an account of the country, entitled "Reminiscences of South America, from Two and a half Years' Residence in Venezuela." On his return to England in 1835 he was appointed engineer to the Manchester and Bolton Canal and Railway. Mr. Hawkshaw was consulted on the subject of the gauges by the directors of the Great Western Railway, and gave a decided opinion that the broad gauge should be discarded, and that the gauge adopted by the Stephensons, which was then in use on the Liverpool and Manchester Railway, should be used in its place. He advocated its adoption in order to prevent the Great Western line from being isolated from the entire railway system of England. At that time the broad gauge had been laid only between Paddington and Maidenhead, and the adoption of his policy would have been very advantageous. Some of the directors, however, maintained

Digitized by Google

that the severance of their line from the network of the kingdom was itself an advantage. In 1840 Mr. Hawkshaw was appointed chief engineer of the Manchester and Leeds Railway, in succession to George Stephenson. This line had been commenced, in 1836, under Stephenson, and the works had been partly carried out before Hawkshaw's appointment. He showed the practicability of steeper gradients than had then been adopted, and which were found to be necessary on some branches of this line. He claimed that they were desirable where a circuitous route might thus be avoided. Stephenson advocated tunnelling through hills, and the securing of a level line. Hawkshaw opposed Stephenson's views, and had the satisfaction of seeing his own received with favour. On the incorporation of the Manchester and Leeds Railway with the Lancashire and Yorkshire Company, Mr. Hawkshaw was appointed engineer of this group of railways, and designed many of the lines and branches on the system. He carried out the very costly extension of the South-Eastern Railway from London Bridge Station to Charing Cross, with a branch to Cannon Street, and constructed the two railway bridges across the Thames, together with the two terminal stations. In Russia he constructed the Riga and Dünaburg and the Dünaburg and Witepsk lines. In Mauritius the Government Railways were completed under his direction.

He also devoted much time to the construction of docks and harbours. The Penarth Harbour and Dock near Cardiff, the Albert and other docks at Hull, the South Dock of the East and West India Dock Company, and the Holyhead Breakwater, of which he was appointed engineer on the death of Mr. J. M. Rendel in 1856, are among his most important works. In 1862, at the request of the Viceroy of Egypt, he reported on M. de Lesseps' Suez Canal scheme, and it was owing to his strong recommendation that the work was not then abandoned. In 1860 he was appointed sole Royal Commissioner to inquire into the water supply of Dublin, and his scheme was carried out. He designed and superintended the construction of the fortification of Spithead forts, and was a member of the Government Commission on Fortifications. In 1862, on the failure of the great sluice at St. Germains, near Lynn, he carried out successfully the difficult work of preventing the tidal waves from flooding the low-lying lands of Norfolk. He erected an ingenious timber dam, and the drainage was effected by means of sixteen large iron syphons laid over the dam, and acting as a substitute for the fallen sluice.

He was President of the Institution of Civil Engineers in 1862–63, and some passages in his presidential address certainly deserve quotation. With regard to discovery and invention, he said that "there is no such thing in the sense which is sometimes attached to the words. Men do not suddenly discover new worlds, or invent new machines, or find new metals. There is nothing really worth having that man has obtained that has not been the result of a combined and gradual process of investigation. A gifted individual comes across some old footmark, stumbles on a chain of previous research and inquiry. He meets, for instance, with a machine, the result of much previous labour; he modifies it, pulls it to pieces, constructs and reconstructs it, and by further trial and experiment, he arrives at the long-sought-for result." In his concluding remarks he said that "no agency could be compared in its effects, or in its tendency towards the amelioration of the condition of mankind, with the establishment of railroads, the electric telegraph, or with the improvement in steam navigation. For in constructing railways, telegraphs, and steam boats, and their adjuncts, docks and harbours, and moulding and fashioning the face of the material universe to the wants of man, in overcoming its barriers, overleaping its valleys, and spanning its seas, engineers annihilate both space and time, bring into juxtaposition nations and people, and accelerate, beyond all human expectation, personal communication and that interchange of ideas which is all-important to the advancement of civilisation and knowledge. Distance and separation have led and will always lead to misapprehension and prejudice—to ignorance and mistrust—to rebellion and war; and engineers may feel, when labouring on the great public works that facilitate the intercourse of nations, that they are not merely conquering physical difficulties, but that they are also aiding in a great moral and social work."

In 1870 Mr. Hawkshaw proposed his scheme for a submarine tunnel between Calais and Dover. In conjunction with Mr. Wythes and Mr. Brassey, he had caused borings to be made to a depth of 500ft. through the chalk at St. Margaret's Bay, near Dover, and at Sangatte, on the French coast. He had also chartered a steamer at his own expense to take soundings in the Channel, and had employed a geologist to map out the outcrop of the strata on the French and English coasts. He finally came to the conclusion that a tunnel between England and France was quite practicable. In 1873 he received the honour of knighthood. He visited Brazil in 1874, and examined the principal ports and harbours of that country. He was engaged as sole Royal Commissioner in inquiring into the means of purifying the Clyde. He was President of the British Association at the Bristol meeting in 1875. His presidential address reviewed the progress of engineering from the earliest times in Egypt and Mesopotamia up to the times of the Lancashire and Yorkshire Railway, and dealt not only with civil engineering, but also with mechanical engineering and architecture. But his connection with the Severn Tunnel will perhaps be considered as his most important engineering work. During thirteen years, while the tunnel was being constructed, the large inflow of water from underground springs made the work extremely difficult, and it was feared at one time that it would be impossible to complete the work. Sir John Hawkshaw's skill and energy surmounted all obstacles, and in 1885 the first train passed under the Severn between England and Wales. In 1888 Sir John Hawkshaw retired from the profession, and his work devolved upon his son, Mr. J. C. Hawkshaw, and Mr. Harrison Hayter. The mere recital of Sir John Hawkshaw's work forms a continuous record of useful labour for the advancement of the civilisation and material progress, not of his own country only, but of the world. While England can claim such men among her sons, her present great position is likely to be maintained.

THE ATLANTIC RACE.

The race across the Atlantic continues to increase in interest, especially as German shipbuilders and engineers have now entered for it. The "Fuerst Bismarck," belonging to the Hamburg-American Line, was built at Stettin by the Vulcan Shipbuilding Company, and is essentially a duplicate of the "Normania," which was constructed by the Fairfield Shipbuilding Company on the Clyde. We understand that the "Normania" has scarcely fulfilled the expectations of her builders and her owners, inasmuch as she has not yet equalled the best run of the "Columbia," a smaller ship, with 3,500 less horse-power. The builders of the "Fuerst Bismarck" took much more time to build their ship than the Fairfield Company, and to a certain extent had the benefit of their experience in some matters connected with the construction both of the ship and the engines. The "Fuerst Bismarck" registers 8,616 tons, is 502½ft. long, 57½ft. broad, and 34½ft. deep. Her engines are of the triple-expansion type, with cylinders of 40in., 67in., and 106in. diameter. She has nine double-ended boilers, her coal bunkers have a capacity of 1,700 tons, and on her trial trip she averaged 20·55 knots.

The "Fuerst Bismarck," in her voyage from Southampton to Sandyhook, particulars of which have just been received, made the distance in 6 days 14 minutes 15 seconds, or, taking the course pursued by the "City of Paris" in her famous run of 5 days 19 hours 18 minutes, and allowing the average speed which she actually made, the "Fuerst Bismarck" would have got over the distance in 5 days 22 hours and 54 minutes. Captain Albers says she was not pushed in any way, and predicts, as she has done so well in her maiden voyage, that after a few more voyages she will beat all records. Another point in her favour is the consumption of coal. The "City of Paris" burned every day about 335 tons of coal, while the "Fuerst Bismarck" is said to have burnt only 280 tons. Such records open up prospects which deserve serious consideration from our shipbuilders and marine engineers.

Letters to the Editor.

THE "STANLEY" BOILER.

To the Editor of "Industries."

Sir,—I thank you for your notice of the test of the above boiler in your valuable paper of last week. It being in the same issue as the test of the boilers and engines of the s.s. "Iona," your readers will have a good chance of comparing a few of the results. That they may do so more closely I send you a copy of Mr. Nichol's report, which I am sorry I had not time to send you during last week, but trust you may find space for it and the following remarks in your next issue.

I see in the "Iona's" trials the grate is very small, and the ratio to heating surface is very high, 75·2, compared with 29·86 in the "Stanley" boiler, but forced draught was used instead of natural. The boilers would also be covered with composition. The temperature of the outside air was 62°, as against 50°, or rather, as the boilers were in the stokehold, about 100°. All these things make a difference of about 20 to 30 per cent. against the "Stanley" boiler in evaporation. I also burnt 25·5lb. of coal per square foot of grate, as against 22·4lb. in the "Iona." The feed-water was 51° as against 106°, and the pressure atmospheric as against 165lb. per square inch. Yet the "Stanley" boiler evaporated 7·84lb. of water per lb. of coal with natural draught, as against 9·15lb. with forced draught; 9·14lb. from and at 212°, as against 10·63lb.; 200lb. per square foot of grate, as against 205lb.; 6·715lb. per square foot of heating surface, as against 2·73lb. As the weight of the "Iona's" boilers is not given, I can only roughly compare this item. The "Stanley" boiler, however, did the very high evaporation of 244lb. of water per ton weight of boiler, smoke-box, funnel, and water included, and taking the weight of the "Iona's" boilers, &c., at 100 tons, they only did 86·16lb. per ton.

If not trespassing too much on your valuable space, I should now like to say something in reply to the queries at the end of your notice. I am certain from the experiments I have had that it will not prime in actual work, but if it should be found to do so, I can easily remedy it in this and all future boilers by keeping the top of tubes lower down. The water line in the sectional view you gave is higher than that at which I propose working it; this I omitted to correct before sending you the drawings.

The steam space is quite sufficient, and can be increased as required by a larger dome in future boilers. Your next query is answered by the remarks above regarding the water line.

In conclusion, I may say that one or two little things have shown themselves to me in the trials, whereby all future boilers of the "Stanley" type will be greatly improved. Mr. Nichol's report includes a statement of results with this boiler burning 15lb. of coal per square foot of grate instead of 25·5lb., and which shows the high evaporative efficiency of 11·07lb. of water per lb. of coal from and at 212°. With the large consumption of 25½lb. of coal per foot of grate, and the most unfavourable conditions of the temperature of air and feed-water, and the exposure of the boiler, under which it was tested, I think none can deny that the tests of this boiler are highly satisfactory. If the test had been of longer duration the results would have been much better, as the water evaporated in the first half-hour was little more than one-half of that during the other two half-hours.

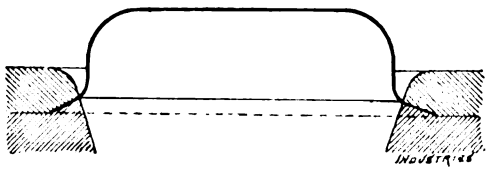
Yours, &c.,
H. B. Buckland.

Hamburg Chambers, Newcastle-on-Tyne, 2nd June, 1891.

THE WENHAM COMPANY v. THE CHAMPION GAS COMPANY.

To the Editor of "Industries."

Sir,—Whilst agreeing in the main with your editorial remarks on this remarkable trial, it would have been more satisfactory if the defendants had had scientific witnesses as well as the plaintiffs; the legal and scientific weight appeared to be all on one side.



Yours, &c.,
Rock Ferry, 1st June, 1891. B.A.M.

ENGINE INDICATORS.

To the Editor of "Industries."

Sir,—I am glad to observe from your last issue that my friend Professor John Perry is turning his attention to the construction of engine indicators. The form illustrated appears very neat indeed, and for permanent immoveable attachment to a cylinder may be found very convenient. The pressure-indicating apparatus, with the exception of the multiplying gear, is the same as that of my indicator patented 24th September, 1886 (No. 12163), and described in a paper read before the S.S. and E.W. Mining Engineers, 5th April, 1888.

Professor Perry uses the angular deflection of the plate, while I used its linear deflection. He also uses a flat plate clamped firmly at the edges. I used a dished plate with rounded edges, spun in the form shown below, in order to allow of free

Section of Smith's Indicator Disc.

angular deflection at the edges, and thereby increase the flexibility for a given size and strength. As multiplying mechanism I used a fine watch chain winding on a drum ⅛in. diameter, and a thin steel tube 2in. long as lever, thus obtaining a ratio of multiplication of 20 as against 4 in the ordinary indicators, the whole weight of my transmitting and multiplying mechanism, including pencil, being $\frac{1}{10}$oz., against ¾oz. in Richards'. The equivalent piston weight in my instrument was ⅛oz., while it is 1½oz. in Richards'. My spring plate is 1¼in. diameter; Professor Perry's seems to be 1¼in., and he has, therefore, probably a still smaller equivalent piston weight.

A mirror and beam of light as multiplying mechanism was used on indicators before the date of my patent. For ordinary use with a portable indicator, I cannot see how the scale of the indicated pressures can be determined with any accuracy and readiness combined. If, however, the indicator, its mirror, lamp, lens, and diagram screen all be permanent fixtures on an engine, the pressure scale of the movement of the spot of light can be determined directly by experiment, and can be marked upon the screen. I see no reason why each end of each cylinder of every steam engine should not have its own permanently fixed indicator.

I do not know how far Professor Perry has yet tested his indicator. I should like to learn whether he does not find the two chief difficulties I found in my similar instrument. Firstly, I soon abandoned steel plates because of the steam rapidly rusting them. I tried steel plates silvered by electro-deposition, but the heating and cooling, combined with the continuous bending, made the silver soon peel off. I then used hard phosphor-bronze plates, against which I can find no similar objections. But I have found that the large surface of the spring plate and its box led to such large condensation of steam that the indications were not trustworthy. For this reason I laid aside the instrument three years ago, and have not since had any time to try to get over this defect. Professor Perry's box and plate are slightly smaller than mine, but there is so little difference that I can hardly think that this defect is absent from his instrument. I shall be most happy to hear that he has succeeded in overcoming this difficulty.

Yours, &c.,
Robert H. Smith.

THE ZONE SYSTEM OF RAILWAY RATES.

To the Editor of "Industries."

Sir,—As you were the first among your contemporaries to direct attention to the Zone System of Railway Rates, I hope you will continue to keep the subject before the public, and urge that inquires be made as to how far it is desirable and practicable in this country, for in this, as in many other things, the intitiative for reform is likely to come from private and not from official sources. The pamphlet mentioned in your last issue, which has been published at the office of the Glasgow *Evening Citizen*, is an example of what I mean. Your first article was founded on the original letters which appeared in that paper, and these were written by a special commissioner who was employed by the proprietors of the *Citizen* to inquire and report on the matter. He indicated some of the applications which might be made of the system in Scotland; but I have no doubt many other instances will occur to some of your readers. The system might at least be incorporated in the circular routes which are now to be found in several large towns or their neighbourhoods. In both Glasgow and Edinburgh, for instance, we have such circular lines, and I am convinced that the traffic would be immensely increased if there were an omnibus service with a uniform charge. I understand that the directors of the subway railway which is now being constructed, and which will describe a smaller circle than the one already existing, have decided to have such a service, and the same has been suggested on another line which is being projected by the Caledonian Railway to take in some of the suburban districts. In London, of course, the system might find many applications, both locally and otherwise. The objection that most English railways are already running too near their full capacity only proves that that capacity must be extended, for this argument would have blocked progress in any department. The means of communication of a country must always be fully equal to the demands made upon them. In addition to the pamphlet mentioned in your last issue, I would commend to the attention of your readers, who are interested in the subject, a paper recently presented to Parliament (Commercial, No. 11, 1891) in which further particulars will be found of the rapid development of traffic on Hungarian railways, where the system of zone tariffs is in operation.

Yours, &c,

Glasgow, 30th May, 1891. C.E.

THE PROFESSIONAL POSITION OF CHEMISTS.

To the Editor of "Industries."

Sir,—The report of the meeting of the Institute of Chemistry which appears in your issue of the 15th inst. raises some rather curious reflections to an outsider, and especially that part of it which gives an abstract of Dr. Odling's address, "On the Relations of the Chemical Society to Professional Chemistry." He stated that the function of the Chemical Society being the advancement of pure science it followed that it had no concern with the furtherance of professional interests. His whole argument rested on the assumption that from a financial point of view it was expedient that the number of Fellows of the Chemical Society should be maintained. That is to say, that the Society is to a large extent a financial or commercial concern, and in order to keep it going a certain number of subscriptions are absolutely necessary, and in return for these the subscribers are to be allowed to write the letters F.C.S. after their names. Now it is wonderful how ignorant the public still is of the meanings of the letters which people like to add to their names, and also how much a few such appendages raise the wearers in their estimation. Those, indeed, who most like to use them stand most in need of raising. I wonder if Dr. Odling has never discovered that the best scientific work of any society is generally done when it is young and struggling, and when it has got within it a band of enthusiastic workers. When it becomes large it too often degenerates into a struggle to making ends meet in the payment of officials, of the rent of large and pretentious premises, and generally in maintaining its respectability.

The report raises the questions, Why is it necessary to maintain a separate existence for the Chemical Society and the Institute of Chemistry? and why should the profession of chemistry be placed on a different basis from any other?—for I may assume that the members of both bodies claim to be chemists. I understand that the Institute was founded as a protest against the abuse of the Society which was made by some unworthy members. The Associateship, I believe, is conferred on those who satisfy the examiners that they have gone through a course of study such as will give them a fair knowledge of the subject. I would suggest another grade, that of member, for those who are qualified to perform the ordinary duties of a professional chemist, either analytical, manufacturing, or consulting, or to act as a teacher of the subject, while the position of Fellow should be reserved for those who had really distinguished themselves in their profession either by their researches or practical work. If that arrangement were carried out, there are no reasons why the Chemical Society and the Institute of Chemistry should not amalgamate and form a strong body, similar to the Institution of Civil Engineers, which includes all grades of the profession. In my opinion it is altogether a mistake to separate theory and practice in any arrangements whatever, and such an amalgamation would lead to the advancement of pure chemistry, and to the raising of the position of professional chemists.

Yours, &c.,

M.A.

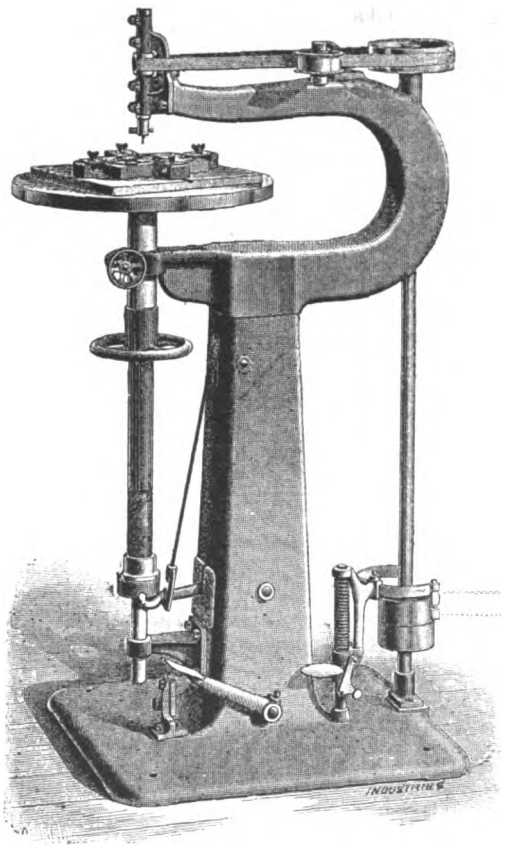
Glasgow, 28th May, 1891.

STEAM ENGINE JACKETS.

To the Editor of "Industries."

Sir,—There is one point connected with the design of the engines of the "Iona" and of the experiments of the Committee of the Institution of Mechanical Engineers to which I would like to direct attention, and on which I would like to have the opinion of some of your readers. Quoting from your description of the engines, you say that "One of the principal features of these engines was the arrangement of the cylinders. The high-pressure cylinder was placed in the middle, and had three metals or walls around it. Counting from the inside, the first metal is the working barrel. Between the first and the second metal a space forms a steam jacket, at full boiler pressure. This is the only jacket about the engines, and is the one referred to throughout the Report. The space between the second and the outer wall is partly the receiver between the first and second cylinders, but mainly it is the receiver between the second and third cylinders. The jacket, therefore, gives off heat inwards to the first cylinder and outwards to the receivers."

This is a very ingenious arrangement, but it is contrary to ordinary practice, in which we seldom find the high-pressure cylinder jacketed. I suppose that that practice is the result of experience, or probably arises from the fear of dry or slightly superheated steam making it difficult for the pistons to work smoothly, a certain amount of condensation being considered necessary for lubrication. But the design of the engines of the "Iona" seems to be justified by theory, which requires that all steam engines should receive their steam at the highest temperature possible. For multiple-expansion engines, we ought therefore to have a superheater for the steam before it enters the high-pressure cylinder, and "hot pots" between the other cylinders, as was done by Mr. Cowper. But these arrangements are very clumsy, and altogether unsuited for marine engines. The design of the engines of the "Iona," however, carries out these theoretical arrangements to a very considerable extent, as the high-pressure cylinder is jacketed, and the jacket, at the same time, acts as a "hot pot" for the other two cylinders. The experiments show a very considerable amount of condensation in the jacket, but they do not show the effect of the jacket itself on the efficiency of the steam. I do not know whether the construction of the cylinders of the "Iona" will allow of the conditions of the use of the jacket being varied, if it does some most interesting experiments might be made. In the meantime, perhaps some of your readers will state their experience in such matters.



Yours, &c.,

Marine Engineer.

Liverpool, 29th May, 1891.

AN IMPROVED ROUTING MACHINE.

The accompanying illustration, for which we are indebted to our contemporary the *American Machinist*, represents a routing machine of simple construction, specially designed for meeting the requirements of publishing houses, electrotypers, and others, where machines are required to cut down large surfaces on engravings, &c. A rigid overhanging arm, above a vertically moveable table, supports a cutting spindle of steel, which can be run at 6,000 to 8,000 revolutions per minute. It is driven by an endless belt, arranged with a "stenting" pulley for governing the tension. The vertical shaft, extending to the base of the machine, affords a convenient mode of driving, which effectually eliminates any tremor that otherwise might be imparted from the driving belt.

The work to be routed is secured to a movable holder or loose iron plate, and passed beneath the cutter over the surface of the table by hand. This plate possesses sufficient inertia to resist the rotative force of the cutter, and enables the operator to move the work readily in the desired direction. Suitable clips, arranged in slots, are provided for fastening either mounted or unmounted plates to the work holder. The table may be moved vertically for entering the cutter, and for withdrawing the same from the work, by means of a conveniently arranged pedal for the right foot. A hand-wheel beneath the table provides an adjustment for controlling a uniform depth of cut. The table is also counterbalanced by a weight suspended within the column of the machine, making the movement of the table very sensitive. The adjustment for depth, combined with the vertical movement of the table, permits the machine to be successfully used for boring nail holes in zinc and electrotype plates, or for boring out mortises if desired.

The work holder is 12in. square, and it will take in plates 9in. in width. The driving pulley is 5in. diameter by 2¾in. wide, and the floor space required is 24in. by 31in.

The makers of this machine are Messrs. John Royle & Sons, Paterson, New Jersey, U.S.A.

Reviews.

Elementary Lessons in Heat, Light, and Sound. By D. E. Jones, B.Sc. Macmillan & Co. 1891.

This little work, though it comes into being at the end of a long line of pre-existing text-books, will nevertheless, we believe, be welcomed by a large class of teachers and students of elementary physics, as supplying a want in educational literature which has been widely felt. The author deals with his subject as essentially an experimental one—each law and theory being, as far as possible, introduced and developed through the avenues of either practical experience or suitably contrived experiment. Very complete instructions for conducting such experiments form a noteworthy feature of the book, which contains many useful hints for the benefit of those who desire to put to practical test the various principles with which they seek to familiarise themselves. Sometimes the expositions and, more fre-

Digitized by Google

quently, the definitions given are, as it appears to us, hardly sufficiently explicit to guarantee perfect clearness in the beginner's ideas; and we do not consider that the author is wise in recommending his readers, on first attacking the subject, to omit all that he has printed in small type, many important points (as, for example, the nature of a coefficient of expansion, p. 16) being hardly rendered intelligible without reference to the less prominent paragraphs. On the whole, however, the style of the book is concise and clear, and its value is considerably enhanced by a large number of excellent illustrations.

MIXED METALS OR METALLIC ALLOYS. By A. H. Hiorns. London: MACMILLAN & Co. 1891.

In this little volume the author gives a useful abstract of the researches of various authorities on alloys. The arrangement adopted is similar to that employed by Guettier in his "Guide Pratique des Alliages," the alloys being arranged in the following order:—Copper alloys, including brass and bronze; nickel alloys, including German silver; tin alloys, including solder, fusible metal, and Britannia metal; lead alloys, including pewter and shot metal; mercury alloys or amalgams; alloys of the precious metals; and iron alloys. The author has largely drawn on the lectures of his teacher, Professor Roberts-Austen, and reproduces several of the illustrations given in the Professor's Cantor lectures before the Society of Arts.

SEWAGE TREATMENT. By H. L. Hinnell. Bolton: TILLOTSON & SON. 1891.

A short descriptive sketch enumerating the different methods of dealing with water-carried sewage has long been wanted, and the author has endeavoured to supply this desideratum in the pamphlet under review. Most of the small handbooks, which have been brought to our notice during the last few years, have been written by men who had "fads" to put forward or patents to exploit, but Mr. Hinnell, although he has evidently had considerable experience in the actual working of many of the processes described, refrains from advocating any special treatment for general adoption on the ground that no one system could be mentioned which would be advisable to adopt in all cases. The author gives short descriptions of about twenty different processes, and although he has only given the barest outlines of some of these, the book will be of value to engineers and members of local boards and sanitary authorities, who are contemplating constructing works for the purification of their sewage, as it forms a valuable guide, which will aid them in selecting that process or processes which are most adapted for their special needs. It is unfortunate that many of the methods which have been brought before the public in recent years, whilst possessing in many cases undoubted merits, have had their virtues extolled in quack phraseology, and described by engineers and others interested in their promotion in language which is wanting in accurate chemical description, and we are afraid that the author himself, who appears to be well trained in the engineering parts of the sewage problem, has not made use of his chemical knowledge to eliminate the absurd chemical statements which have been brought forward by advocates of some of the processes described. Some men are so fond of making rash and sweeping generalisations, such as "it is difficult to find a more efficient, harmless, and economical manner of treating sewage" than that of bringing about "the defecation and deodorisation of the sewage by means of lime, tar, salts of magnesium, or *other chemicals*," which, when italicised (as we have done), are shown to mean nothing, but which, unfortunately, are flaunted about for the edification of the unscientific public as important, accurate, and reliable statements. We strongly object to such expressions as "the *grosser* part of the suspended matter," "the cheapest known form of alumina and iron," "the alumina ferric process," "ferozone," "polarite," ferozene (ferozone ?), "polarised oxygen,"&c., which we find in the accounts of several of the processes which the author attempts to describe. We admit that in most of these cases the author is not so much to blame as the inventors themselves, who describe their patents in such meaningless verbiage, but we think that it would have been far better if Mr. Hinnell had taken some little trouble in putting before his readers these processes in, we will not say scientific language, but in intelligible English, instead of leaving them in the dark as to the meaning of these ambiguous phrases.

The subject of sewage treatment undoubtedly presents many difficulties from a chemical point of view which have, no doubt, wisely deterred chemists from attempting explanations when such explanations would only be incomplete and unsatisfactory in the present state of our knowledge; but the average sanitary engineer rushes in where the chemist hesitates to tread, and gives out to the public what purports to be a full and complete account of the mysteries which have been left unsolved by wiser and more cautious men. Notwithstanding these faults, we commend the book to the consideration of those of our readers who are interested in the sewage problem, as the author's careful classification of districts and remarks on the various circumstances which have to be taken into consideration when determining what system of treatment and disposal is most advantageous for any particular town are worth their very careful perusal.

THE VALUATION OF GAS WORKS FOR ASSESSMENT. By T. Newbigging, M.I.C.E. London: WALTER KING. 1891.

Mr. Newbigging has such a complete mastery of the subject on which he writes, and is so well known as an expert on all matters related to the construction and valuation of gas works, that it is almost unnecessary for us to commend his new essay to those of our readers interested in this problem, either from the assessment committee or appellants' point of view. The author has done good service in pointing out those particulars which usually give rise to the greatest contentions between the parties concerned. We note that Mr. Newbigging contends that a quarter's rent may fairly be deducted from the assessment value of the undertaking, and as this amounts to one-fourth part of the gross estimated rental, a gain on this point is much to be desired by the gas companies. On the whole, we are convinced that Mr. Newbigging has been urged to state the case as impartially as possible, and no doubt the publication of his views on the matter will tend to smooth any difficulties which may arise in future disputes on this important question. Although the subject is primarily applicable only to gas works, many of the points raised can be urged with equal force for water works which are not under the control of the local authorities.

CHARLES' BRUSH HOLDER.

WE illustrate herewith in Figs. 1, 2, and 3 a very simple and effective form of dynamo brush holder designed by Mr. P. J. Charles, electrician to Messrs. Harland & Wolff, Belfast. By rotating the handle the holder is free to move on the pin of the rocking bar. The brush can thus be readily moved along the commutator to any desired position. A quarter turn of the handle fixes the split sleeve to the pin. The adjustment of the pressure of the brushes

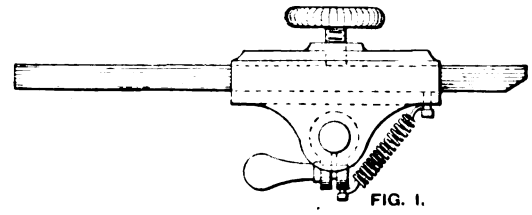

FIG. 1.

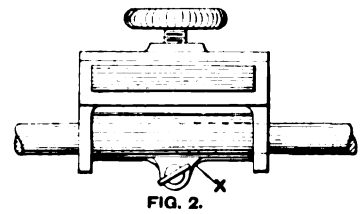

FIG. 2.

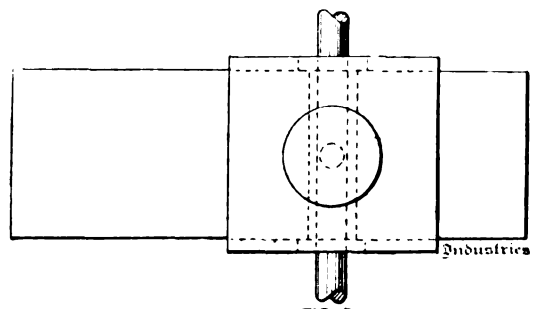

FIG. 3.

is effected by the same handle, and the arrangement has the advantage that the pressure is felt by the hand, so that the attendant knows exactly what pressure he is putting on—an important detail, too often overlooked. To take the brushes off, the handle is turned to slacken the sleeve; the sleeve is turned on the pin and made to grip in a new position. The whole arrangement is beautifully simple and very effective. We have tried this holder and found it admirable, and it is rapidly coming into use.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

AT a meeting of this Institution on the 21st ult., the discussion was continued on a paper entitled "Some Effects of Alternating Current Flow in Circuits having Capacity and Self-induction," by Dr. J. A. Fleming.

Major Cardew remarked that the condenser, on which the experiments mentioned in paragraph 12 of Dr. Fleming's paper were made, had been constructed from imperfect plates, and since then a good condenser, kindly lent by Dr. Muirhead, had been carefully tested for capacity by the alternate current method. The capacity so found was in this case also greater than the capacity given by the makers. The discrepancy, he thought, might be due to the fact that Dr. Muirhead determines his capacities by rapid charges and discharges, which, in consequence of absorption, would give a result too low, whereas in the alternate current method the absorption would have the effect of increasing the apparent capacity. Experiments had also been made by the voltmeter method, described by Professor Ayrton and Dr. Sumpner, and Mr. Swinburne, on the power spent in a one-microfarad condenser when subjected to alternating pressures of 650 volts. The power found was 5 watts, and after a long-continued run the condenser was not much heated.

Dr. Sumpner pointed out that many of the formulæ given by Dr. Fleming could not be used practically without considerable reservation as to the values to be substituted for R and L in the expressions. Since secondary circuits exist in all electrical apparatus in the shape of iron, copper, &c., not infinitely laminated, the changes in the so-called "constants" of the primary coil may be very important. The ordinary formula for the angle of lag between the e.m.f. and current in a coil is $\cos\theta = \frac{\text{Resistance}}{\text{Impedance}} = R\frac{A}{V}$, where A is the current and V the volts. The experiments given in Table I. (section 17) did not show whether any of the rise occurred in the dynamo as well as in the transformer. The same theory accounted for rises in both parts, but, as Mr. Swinburne had pointed out, the primary circuit of a transformer could not act like a coil with self-induction, unless there was some magnetic leakage. In the experiments made at the Central Institution it was found that, under certain conditions, about half the rise was due to the self-induction of the transformer, and the other half to the dynamo. The proportions differed, however, with the ratio of transformation.

Mr. Blakesley mentioned that he published an account of such a rise long before the Deptford station was commenced, and he was not at all surprised when he heard that such a rise occurred there.

Mr. A. Siemens, referring to the change of ratio of transformation, said that more recent experiments, using a different form of transformer, showed that the ratio of transformation was independent of the capacity.

Professor Ayrton inquired what was the difference in the two kinds of transformer used, and Mr. Siemens replied that one was an open-circuit and the other a closed-circuit transformer.

Mr. Swinburne directed attention to the practical points to be attended to in coupling alternators in parallel on mains having capacity. An important point he had recently observed was that, by employing a motor in conjunction with an alternator, the effect of fall of pressure could be neutralised, for weakening the fields of the motor caused it to act like a self-induction. By strengthening the fields of a motor it could be made to act like a capacity. Hence, even in transmitting power over long distances by alternate currents, an attendant at the receiving end could maintain the pressure at that end constant independent of the load by simply varying the strength of the fields of a motor working on the circuit.

Dr. Fleming, in his reply, thanked Dr. Sumpner for calling attention to the parts he had omitted from the paper, and said that some practical method of getting the inductance of a transformer at any load was greatly needed. He, Dr. Fleming, had hitherto failed to get a clear idea as to what Mr. Swinburne's views really were, but he thought that both the orthodox theory and the armature reaction view would be found wanting in some respects. A significant fact, however, was that with large machines of small inductance no rise was observed, whereas when small machines of comparatively large inductance were used the rise was great. Referring to Major Cardew's experiments on condensers, he thought that the observed effects might be due to leakage, for a leak would cause the capacity to appear greater when tested by alternating currents, and less when direct currents were employed. He could not agree with Mr. Evershed about the quantity Lp being of the nature of electromotive force, for, although it was not of the nature of resistance in the sense of being dissipative, yet its dimensions were those of resistance, and only those of

Digitized by Google

e.m.f. when multiplied by current. On the subject of throwing machines in parallel, he pointed out that the procedure depended entirely on the nature of the machines and of the circuit, for the operations necessary to put the large Deptford machines in parallel on the mains were the reverse of those required when the small machines were used. Dr. Sumpner, he said, had greatly over-estimated the magnetising current of the Deptford transformers, for, instead of being 5 amperes, it was, he thought, only 4 amperes.

After this the discussion on "Some Points Connected with Mains for Electric Lighting," by Mr. W. H. Preece, F.R.S., and on "The Most Economical Mode of Feeding a Low-pressure Network," by Mr. R. E. Crompton, was continued.

Mr. Addenbrooke said that the object of Mr. Preece's paper was to point out the economy of the high-pressure principle, whilst that of Mr. Crompton's was to impugn that principle. On examining the question as to the cost of high-pressure mains, he found that to give a 10 per cent. loss in 2,400 yards of feeder supplying 100 kilowatts at 2,000 volts would require a $\frac{7}{14}$ cable, and this, of best Silvertown make, would cost about £165 per mile. This would give the cost of cable about £400 instead of £1,300, as stated in Table I. The cost of the culvert or pipe was taken the same for both the high and low pressure feeder. This, he thought, was unfair to the high-pressure system, and the cost of the transformers and apparatus was also too high. Altogether, the cost of the high-pressure feeder ought to be put at about half that of the low-pressure one under the conditions there stated. These conditions were, however, not practical ones, for no engineer dealing with the alternating transformer system would allow a drop of 10 per cent. in so short a feeder; 2½ per cent. would be much more reasonable. Taking this drop the cost of the cables would come to about £1,300, but the 7½ per cent. saving would mean an increased revenue of about £160 per annum.

Mr. R. C. Jackson described the method of laying underground concentric mains as carried out by the Newcastle-upon-Tyne Electric Supply Company, and exhibited samples of the work. The system, he said, was a draw-in and draw-out one, using cast-iron pipes and concentric cables for 2,000 volts pressure. The joints were made in junction boxes by bolting copper rings cast to thimbles, in which the ends of the cables were "sweated," to the top of porcelain insulators. The same points served also as connections for service lipes. The advantages claimed were:—Simplicity and small cost, a six-mile circuit to feed 12,000 lamps, with a variation of pressure never exceeding 6 per cent., having been laid at about £1,100 per mile.

Mr. Kapp said the case which Mr. Addenbrooke had made out for the A.T. system was not strong enough, for Mr. Crompton's calculations were vitiated by not taking the extra cost of plant into account. With a low-pressure feeder of 90 per cent. average efficiency, about 30 per cent. more boiler, engine, and dynamo power would be required, as well as 30 per cent. more wages, &c., than for a high-pressure system. Mr. Crompton would thus have to lay down 30 per cent. more plant and pay 30 per cent. more wages and interest for the privilege of using a low-pressure feeder.

Major-General Webber said Mr. Crompton wished them to believe that the A.T. people had now found that it would be necessary to use a low-pressure network such as used in direct-current distribution. This, he said, was by no means new, for Mr. Ferranti, as long ago as 1885, described a system like the one now mentioned by Mr. Crompton.

Sir W. Thomson inquired what ratio the energy sold had to that generated in the various systems of distribution. In his opinion, the comparison would be favourable to the low-pressure system wherever it was practicable. In dealing with large conductors, both Mr. Preece and Mr. Crompton seemed to have ignored the fact that the conductivity was less for alternating currents than for direct ones. Conductors of 2cm. diameter offered 8 per cent. more resistance when the frequency was 80, whilst for 3cm. diameter the increase was 31 per cent. On the whole, he thought it injudicious to rush to alternate currents for distribution purposes, and he himself rather inclined to continuous current distribution by feeders, as described by Edison.

Mr. A. Siemens thought the principal object to be aimed at in designing stations was *simplicity*, and the design for a particular district must be guided largely by local circumstances. In his opinion, the discussions on both Mr. Crompton's papers had converged too much on high and low pressure. Speaking of cables, he said that, in addition to the theoretical conditions referred to by Sir W. Thomson, practical and financial points had also to be kept in view. In making concentric cables for the London Electric Supply Corporation, they had found that putting in a jute core increased the diameter of the cable and added considerably to the cost. It was cheaper for them put in extra copper to make up the conductivity.

Mr. Swinburne said the "skin effect" could be minimised, even in large conductors, by making them, say, in six smaller cables stranded round an inactive centre.

Sir W. Thomson agreed that if each wire of such a cable had as much external surface as another wire the full conductance would be obtained, but this condition was not fulfilled in cables as ordinarily constructed, and in conductors 2cm. or 3cm. in diameter the conductivity for alternating currents is seriously diminished.

Mr. A. E. Mavor said that by soaking the separate wires in an insulating medium before stranding, considerable resistance could be got between the strands; a light serving of cotton did not seriously increase the diameter of the cable. In this way he thought Mr. Preece's square inch section could be obtained without much diminution in conductivity for alternating currents. He characterised Mr. Crompton's estimate of £1,300 for 2,400 yards of concentric cable as absurd, and he assured Mr. Preece that great attention was being given to the construction of mains. He was also of opinion that rubber would be superseded by cheaper dielectrics. On the subject of feeding a network he had no doubt but that high-pressure cables would be much cheaper than low-pressure ones.

Mr. Preece, in reply to Sir W. Thomson, said that in one alternate current system with which he was acquainted the coal burnt per unit sold was 17lb., whilst per unit generated it was 8lb. In Rome, however, these numbers were 10lb. and 8½lb. respectively. This satisfactory result he attributed to the system of "banking" the transformers. Sir W. Thomson, he remarked, had said a great deal in favour of low-pressure systems with numerous stations, but in so doing he had apparently overlooked the fact that working expenses were greatly increased by this duplication of stations.

Mr. Crompton, not being present, did not reply.

EXPERIMENTS WITH ALTERNATING CURRENTS OF HIGH FREQUENCY.*

The recent meeting of the American Institute of Electrical Engineers will long be remembered by those present, not only on account of the brilliant experiments shown in connection with a lecture given by Mr. Nikola Tesla, but also for the many possibilities which it suggested in the development of the artificial illumination of the future. For the purpose of his experiments, Mr. Tesla employed an alternating machine with 400 poles, which, when run at full speed, permitted him to obtain 20,000 alternations per second. The currents of this machine in all of Mr. Tesla's experiments were first run through a condenser in order to avoid the possibility of injury to the machine. The machine itself was set up in the electrical workshop of the college, and was driven by an electric motor, the speed of which could be varied by a switch on the lecture platform.

Mr. Tesla introduced his subject by the remark that modern science has been able to make rapid strides by the recognition of ether as the medium of transmission of vibrations of various forms which manifest themselves to our senses. We are therefore able now to see things in a different light than was formerly the case, and being tolerably well able to explain them, the truth cannot be hidden much longer. The answer to the question, "What is Electricity?" we were not yet prepared to give. We were justified in assuming, however, that electric phenomena are ether phenomena, and we may consider the phenomena of static electricity as phenomena of ether under strain, and those of dynamic electricity and electromagnetism as phenomena of ether in motion. The lecturer, while expressing the highest consideration for the work of Dr. Lodge, was not in entire accord with the views advanced by him, which he considered to be more of the nature of ingenious explanations than of a probable theory, the lecturer contending that there can be no two electricities. Alluding further to the electromagnetic theory of light, and to the Hertz experiments and those of Dr. Lodge, and their application to the production of an efficient source of light, the lecturer considered the electromagnetic waves as unavailable for the production of luminous effects, for the reason that long before we could reach the necessary frequency the conductor would become opaque to the passage of the waves. The lecturer thought that electromagnetic waves, unless they have the frequency of true light waves, cannot produce luminous effects. Not so, however, with the electrostatic waves or thrusts. These, no matter what their frequency, can excite luminous radiation. He reasoned that the static effects in the Hertz and Lodge experiments were excessively small, due to the fact that they were produced in a practically closed coil, the spark acting as a bridge, making the coil practically continuous and depressing the potential. To obtain the desired difference of potential we must work with an open circuit generator of high potential of high frequency to enhance the electrostatic effects, and it was the recognition of this fact which led the lecturer to the results he showed.

In carrying out this idea of obtaining enormous differences of potential, the lecturer at once encountered the difficulty of obtaining the requisite insulation for the induction coil employed by him. His experience demonstrated that what we consider the best insulators, such as glass and rubber, are inferior to others, not formerly so considered, such as oil and wax. The lecturer then started a spark coil in action, the primary of which was in connection with his alternator which was speeded to give from 10,000 to 11,000 alternations per second. The coil emitted a clear note, which rose as the number of alternations was increased. As the discharges took place between the terminals of the coil, an exhausted Geissler tube held in proximity to the discharge did not light, but upon blowing out the arc the tube lighted up, which was due to the rise of potential caused by the rupture of the arc. This effect the lecturer considered as purely electrostatic.

Mr. Tesla then showed the influence of insulated bodies having considerable size upon the spark length demonstrating the effect of capacity upon the nature of the discharge. Thus, when we attach an insulated body to the terminal of the coil, the potential may be raised or lowered. He showed this by wrapping an insulated wire of about one foot in length about one terminal of the coil, and touching the other terminal with a brass sphere held in the hand; under these conditions streams of light emanated from all sides of the wire. When the sphere was removed, however, the streams disappeared almost entirely. He then cut off the wire in successive lengths, and the stream discharges became more marked and brilliant. He then attached a fine platinum wire to the terminal, which also showed the streams to a remarkable degree, and kept up a continuous vibration to and fro. He also showed a pin-wheel effect, the wheel being rapidly rotated with streams issuing from the two points. Another experiment consisted in attaching two spheres of about 4in. diameter to the terminals. The spark passes first between the two points nearest to each other on the spheres, then works up toward their tops, is extinguished and is re-established at the first point, this being continuously repeated. The neighbouring exhausted tubes and lamps were illuminated and extinguished in unison with the action of the spark between the spheres. These, the lecturer pointed out, were not electromagnetic vibrations like the Hertz waves. He showed how by the use of the dielectric the spark is induced to jump between the separated spheres due to the increase in the specific inductive capacity of the medium, and he also demonstrated that the streaming discharge passed easily through thick glass plates, rubber plates, and a book. The lecturer then showed these static effects in a non-striking vacuum. A tube of this nature when connected to the machine glowed brightly, and the terminals became incandescent. The lecturer remarked that if, instead of using a filament in a lamp—which necessarily limited us in the degree of incandescence which we could practically employ—we could employ solid blocks of carbon, much higher efficiency could be obtained. Based upon this reasoning, he has constructed a lamp which he showed, containing two blocks of carbon in non-striking vacuum. When connecting these two carbons to the two terminals of the coil or one to one terminal and the other to a body of some size, the blocks can be raised to high incandescence.

(To be continued.)

* Abstract of a recent paper read by Mr. Nikola Tesla before the American Institute of Electrical Engineers. For the above abstract we are indebted to our American contemporary the *Electrical Engineer*.

THE PHYSICAL SOCIETY.

At a meeting of this Society on the 22nd ult., Professor W. E. Ayrton, F.R.S., being in the chair, Mr. C. J. Woodward exhibited Dr. Schobben's form of lantern stereoscope. This instrument consists of a double lantern by which the two pictures of a stereoscopic slide are projected on a screen. The two pictures are coloured complementary tints by placing pieces of red and green glass in front of the lenses, and each observer views the overlapping images through spectacles, the eyeglasses of which are also coloured red and green. The stereoscopic effect is very striking. Mr. Boys stated that he had tried to obtain a similar result with the aid of polarised light, by viewing two polarised images through Nicol's prisms. No effect was obtained, owing to elliptic polarisation produced by the screen, but he thought that if a dead gold screen had been used, instead of an ordinary one, the effect might have been obtained.

Professor Perry, F.R.S., then showed a new form of steam engine indicator, which we described and illustrated in our issue of last week. In reply to Mr. Carus Wilson, Professor Perry stated that the deflection of the disc was proportional to the pressure in the cylinder within the limits any particular disc was intended for.

Mr. Addenbrooke thought the instrument an important improvement on its predecessors, and considered it would prove of great service to electrical engineers. Mr. Swinburne said a peculiar merit of the indicator was that it could be permanently attached to an engine like an ordinary pressure gauge. He suggested the use of a small telescope instead of the ray method. The President thought that the instrument could be modified so as to be useful for analysing the shape of the curves representing alternating currents.

After this a paper was read on "Blakesley's Method of Measuring Power in Transformers," by Professor Perry. This paper referred to the supposed error in Mr. Blakesley's formula due to the fact that transformers show magnetic leakage. The proofs of the formula hitherto given have been obtained by treating the equations in the manner first adopted by Dr. Hopkinson. On this system the reactions of the primary and secondary currents are represented by the equations—

$$V = R_1 C_1 + P \frac{dN}{dt} \qquad O = R_2 C_2 + S \frac{dN}{dt},$$

where P and N are respectively the turns on the primary and secondary coils, and N is the magnetic flux between the coils. Here it is assumed that there is no magnetic leakage, and the author thinks that on this account the method is inferior to the original method of Maxwell, in which the induced electromotive forces are

Digitized by Google

expressed in terms of coefficients of self and mutual induction. On the assumption that there are no eddy currents Maxwell's equations are—

$$V = R_1 C_1 + L_1 \dot{C}_1 + M \dot{C}_2; \; O = R_2 C_2 + M \dot{C}_1 + L_2 \dot{C}_2,$$

in which, although L_1, M, and L_2 may not be constant, it may be assumed that they are respectively proportional to P^2, PS, and S^2 if there is no magnetic leakage, and if the amount of magnetic leakage bears a constant proportion to the whole flux the three quantities may still be assumed proportional to each other, although M^2 is less than $L_1 L_2$. From these equations we obtain

$$VC = R_1 C_1^2 - R_2 \frac{M}{L_2} C_1 C_2 + \frac{L_1 L_2 - M^2}{L_2} C_1 \dot{C}_1.$$

Hopkinson puts down the last term as zero, but owing to the very rapid rate at which C_1 changes, the last term is very important, even though M may be but a small percentage less than $\sqrt{L_1 L_2}$. On integrating this equation, the first two terms on the right-hand side yield Blakesley's formula, and the last term vanishes in the integral, because, however great the magnetic leakage may be,

$$\int C_1 \dot{C}_1 \, dt = 0$$

when taking over a period, because the functions are periodic. Mr. Blakesley's formula thus appears to hold whatever the magnetic leakage. The paper contains several tables of calculations showing the effect of magnetic leakage on the value of the terms in the equation.

Mr. Blakesley said he doubted the correctness of the assumption that the value of M was the same in the two equations, and thought that the result arrived at must be incorrect.

Dr. Sumpner did not doubt that, if the coefficients could be considered constant, the formula was true, whatever the leakage, but he did not consider that the action of transformers justified such an assumption. If the formula were true, it would also hold if there were eddy currents, as these would merely produce the effect of additional secondary coils. He had analysed Blakesley's method by using a modification of the Hopkinson equations, and had shown that the power, as estimated by Blakesley's formula, had to be lessened by the fraction represented by the expression,

$$X = \frac{\int x \dot{A}_p \int A_s dt \, dt}{e + \int A_p A_s dt}.$$

Where A_p and A_s are the instantaneous values of the primary and secondary currents, and x is such that $N_p = N_s(1 + x)$, where N_p and N_s are the fluxes of magnetism through the primary and secondary coils at the same instant, e is a negligibly small quantity compared with the rest of the denominator. In obtaining this factor no assumptions whatever had been made, and it was easy to see that if A_p and A_s could be assumed sine functions and x a constant, the value of the factor X became x simply. In only one case did X reduce to zero, and that was when x was a sine function of the same period as A_p and A_s. He believed that in actual transformers x was approximately constant.

Mr. Swinburne pointed out that the split dynamometer was merely a wattmeter, and stated that he had transformers which, owing to magnetic leakage, would indicate an efficiency of over 100 per cent. if tested by Blakesley's method. If this method gives an efficiency of 96 per cent., and leakage causes a drop of 2 per cent. in e.m.f., the real efficiency is only about 94 per cent. He thought that the assumption that the currents followed a sine law was equivalent to supposing that there was no loss in hysteresis.

The President said that no one would be more glad than himself to find that Mr. Blakesley's method was accurate, but he could not agree with Professor Perry that Dr. Hopkinson was wrong in abandoning the academical method of Maxwell.

Professor Perry replied to the various points raised in the discussion.

A paper on "Current and Potential Difference Analogies in the Methods of Measuring Power," by Professor W. E. Ayrton and Dr. Sumpner, was postponed.

NOTES ON OILS.

III.

The close of the financial year for the Scotch mineral oil companies has not shown that satisfactory increase in profits which might have been expected from the yearly turnover. Only four companies—the Pumpherston, Oakbank, Broxburn, and Young's—have declared any dividend. This general failure to make the past year profitable may be in part due to increased competition from outside, but the rapid rise in wages and cost of fuel, with the disorganisation of trade caused by the several great strikes, are probably chiefly answerable for this result.

During April extensive trials were made at the works of the Metal Reduction Syndicate, Patricroft, Manchester, with an apparatus for the use of petroleum as fuel, under the direction of Mr. W. E. Smith. The plant employed has been extensively used in Russia, but is new in this country. It consists of a tank for the storage of the fuel, placed above the boiler to be heated. The oil descends by gravitation to the burners, to which is connected a steam pipe from the boiler. Each burner consists of a spray injector with perforated shield, and the oil is injected by steam in such a way that it is "sandwiched" between the steam and a current of air passing through the central channel. The flame is thrown out very prominently, in order to save the burners as much as possible. The evaporation from Russian petroleum refuse equals 16lb. of water per 1lb. of fuel consumed, so that the comparison between coal and liquid fuel required is as 2·5 to 1, whilst in well-set boilers the ratio may reach 3 to 1. The new fuel has the advantage of being absolutely smokeless.

In Mr. Redwood's recent paper, on "The Conversion of the Nitrogen of the Acid Sludge of Oil Works into Ammonia," it was pointed out that the Scotch oil works make about 37,000 tons of sludge per annum, and that it would be possible to obtain therefrom 6,100 tons of ammonium sulphate, worth £68,000, as against the relatively small sum at present obtainable for this refuse as fuel. The author's process, which has not yet been fully worked out, consists in heating the neutralised sludge in an iron retort connected with two "contact" chambers filled with broken brick, where the tar which distils over is acted on by superheated steam. The oily bases are decomposed with the liberation of nitrogen in the form of ammonia. The gases evolved are swept into a gasometer to be used subsequently as fuel for the retorts, whilst the ammoniacal liquor is separated from the neutral tar and run off. Mr. Redwood states that average acid sludge contains 3·498 per cent. nitrogen, whilst 62 per cent. nitrogen is obtained as ammonium sulphate, or only 17·8 per cent. of the total nitrogen. Of the remainder, 63·5 per cent. appears in the gases, the difference being found partly in the neutral tar, and partly in the residues from the retorts. The gas obtained will supply half the required fuel.

A recent report of the British Consul at Batoum, on the Russian petroleum industry, shows the existence of a similar state of things to that prevailing in the Scotch trade. Although there has been an increase of 26 per cent. in output, and of 37 per cent. in value, since 1888, yet business is less satisfactory on the score of profits. One of the best established and organised firms has liquidated, whilst a syndicate has been formed to consolidate several other firms against the increased competition. The inadequate means of transport, currency fluctuations, and the extraordinary unhealthiness of the past year at Batoum, are mentioned in the report as causes for the unsatisfactory result of the year's trading. The output has, however, been considerably increased, and there is no falling off in the consumption.

The patent of the Alboline Oil and Varnish Company for the chemical treatment of linseed and other drying oils, so as to increase their drying properties, is favourably mentioned by a foreign contemporary. The oils are floated on a deep layer of oxygenated water at temperatures varying from 32° C. to 99° C. for several days. A saturated solution of chlorate of potash, manganese oxide, or chromic acid, very gently warmed, may be substituted for the above, but the treatment must be prolonged. The oil treated thus is said to dry well without cracking, and to make excellent varnish. It is decolourised by the process, and its tenuity, tenacity, and elasticity are not diminished.

An interesting paper upon "Turkey Red Oil" has been recently read before the Académie des Sciences by M. Scheurer-Kestner.* After mentioning its usual mode of preparation—namely, by the action of monohydrated sulphuric acid upon castor oil—the author touches on the conflicting views as to the nature of some of its constituents. Some chemists believe it to contain glycerine, whilst others deny that this is an integral constituent. All, however, agree in regarding it as composed principally of a sulphonated fatty acid. Although other oils are often substituted for castor oil in the manufacture, his own researches have been made exclusively upon a Turkey red oil obtained from castor oil by the action of $H_2SO_4.H_2O$. The product thus obtained is of a complicated nature, but consists, for the most part, of sulphoricinoleic acid in which, as Benédikt and Ulzer have shown, the sulphonic group has a different position to that which it is represented to have according to Müller Jacob's hypothesis. Besides this, Turkey red oil still contains undecomposed (unsulphonated) fatty acids, as is proved by their undergoing decomposition or transformation into the sulphonated compounds, as some sulphuric acid is left in the prepared oil, its amount varying with the extent and nature of the washing. The presence of these fatty acids has been surmised by chemists engaged in investigating this product, but who have not arrived at its exact nature or mode of formation. M. Guillard has recently recognised that the acids contain bodies polymerised by the sulphuric acid. According to him, Turkey red oil is composed of sulphoricinoleic acid together with various polymers of ricinoleic acid up to penta ricinoleic acid. These conclusions were published after M. Scheurer-Kestner had occupied himself with the problem for a year. Certain of the latter's results agree with M. Guillard's, but he does not find such highly polymerised ricinoleic acids as that chemist. He attributes this to M. Guillard employing common salt to separate the sulphonate from the washing water. This, with the sulphuric acid present, is liable to form free hydrochloric acid, whose polymerising power M. Guillard has recognised. M. Kestner substitutes sodium sulphate with advantage, and employs no heat in the washings, which decomposes the products more or less. He regards Turkey red oil as containing sulphoricinoleic acid with mono- and di-ricinoleic acids. Raoult's method was used for the determination of the molecular weights, with acetic acid as a solvent. The sulphonate is hydrated, and in this state it is stable at the ordinary temperature, but at 120° C. it loses its water, completely forming insoluble fatty acids and mono-hydrated sulphuric acid. He has observed an important fact in connection with the use of the oil in alizarin dyeing—namely, that the sulphonate gives various tints of yellow, whilst the polymers give carmine tints.

A contemporary draws attention to the possibility of the Chinese "wood oil" being imported to the European markets, as, owing to its unique properties, there are many industries in which its use would be found advantageous. This oil is obtained from the seeds of the Tung tree, or *Allurites cordata*, and with modern oil expressing machinery can be cheaply prepared in large quantities. Although its chemical nature has been investigated by Cloez, its constitution is at present unknown. In China and Japan it is used for caulking and painting the native junks, preserving woodwork, and for varnishing, and as it resists the action of water and exposure to a hot sun, as well as being impervious to the attacks of insects, there can be no doubt that it would be of considerable industrial utility.

* *Comptes-Rendus*, "Revue de Chimie Industrielle," II., 14, page 45.

SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

At a meeting of this Section on the 1st inst., the first paper read was entitled "Gum Arabic and its Modern Substitutes," by Dr. S. Rideal, of St. George's Hospital, and Mr. W. E. Youle, and in it the authors, after describing the natural gums which had been introduced into the London market of recent years owing to the closing of the Soudan to commerce, gave an account of their more important physical properties, and the methods by which their relative value to gum arabic may be ascertained. The authors then discussed at some length the various gum substitutes, consisting of dextrin, fish glue, and various patented mixtures which had been introduced as substitutes for the natural gums. One of the most important methods for arriving at an opinion as to the commercial value of a gum or gum substitute is based upon a determination of the viscosity of its solution, and the authors have carried out a series of experiments with a view of ascertaining the most suitable way of making this test, and how far the different commercial bodies differ in their viscosity values. They described a form of apparatus, which is not open to the objections which may be urged against the common method of ascertaining the viscosity, by noting the time of flow out of a burette, and gave a table of results which they had obtained in this way expressed in absolute units. They showed that these results were similar to those obtained by Poiseuille and others for water and other liquids by careful experiments in a physical laboratory. It was important in commercial work to use, if possible, methods which gave results which could be reproduced at any time, and which did not depend upon the instruments employed. The authors also show that the ghatti gums, which have hitherto, owing to their partial insolubility in water, found little favour for many classes of work, have properties which render them available if due attention be paid to the conditions required for their successful use. The authors have studied the proneness of the different gums to undergo fermentation, their relative hygroscopic characters, and their more important chemical differences. The gum substitutes, which for the most part consist of dextrin, starch, sugar, and foreign

Digitized by Google

substances, are often of very low viscosity, and have an unpleasant taste and smell, which render them of much less value for mucilages and adhesive purposes, but considerable improvements have recently been made in their manufacture, so that now the better class of gum substitutes compete favourably with the natural gums.

A short discussion ensued, in which Mr. Blount criticised the authors' method for ascertaining the viscosities, and Mr. Christie drew attention to a German soluble gum made by a secret process from the natural insoluble gums.

Afterwards Mr. Joseph W. Lovibond gave an abstract of a long paper "On the Quantitative Analysis of Light and Colour founded on the Tintometer Colour Scales," in which he described his recent work with the tintometer. We have already (see *Industries*, Vol. VIII., page 44) given a short description of this instrument, and the valuable work, both commercial and scientific, that can be done by its use. The author in the present paper states that many of the difficulties which were first met with in preparing the standard glasses have now been overcome, and he is confident that his method is one which places the determination of the colour of bodies on a true scientific basis. In the paper, which was fully illustrated by diagrams and models, the author showed how the instrument may be used for ascertaining the colour of the blood, chlorophyll, and allied bodies, and states that he has always been able to express a given colour by numerical value which was capable of being reproduced at any future time. The latter part of the paper was devoted to a discussion on the theory of colour, and the light which the work of the tintometer had thrown upon this complex subject.

In the discussion which followed, Mr. Newlands testified to the value of the instrument over other forms of colorimeters for gauging the colour of caramels and sugars, whilst other speakers argued that a basis of colour classification upon spectroscopic work was more likely to be of permanent value than that based upon the arbitrary glass colour standards adopted by the author. Several of the speakers bore testimony to the great utility of the instrument for estimating minute differences of tint, shade, and fading, which made it indispensable for many different classes of manufacturers.

Notes.

TWO NEW FORMS OF SULPHUR.

Two novel modifications of this most Protean element have been recently discovered by Engel. The first, like that proved to exist in Wackenröder's solution, is soluble in water and very unstable. The other is crystalline, soluble in carbon disulphide and chloroform, and polymerises slowly in the cold, and quickly at a temperature of 100° C., but unlike prismatic sulphur, which changes on keeping into the octahedral variety, it becomes converted into the white insoluble form which commonly constitutes so large a percentage of the material known as "flowers of sulphur."

THE JAPANESE NAVY.

The Japanese coast defence vessel "Hashidate" was launched at the Imperial Dockyard at the end of March. The first attempt to construct a large vessel of steel with high speed was in a despatch vessel modelled after the French ship "Milan." On her trial trip last year this vessel, on a three hours' run under forced draught, made a mean speed of 20·75 knots, and attained as a maximum 21·5 knots. In the construction of steel vessels the material used is purchased in Europe, largely in France, with machinery principally from this country. The "Hashidate" and sister ships are of the following dimensions:—Length, 295ft. 2in.; beam, 50ft. 6in.; draught, 21ft. 2in.; aft displacement, 4,300 tons. There are numerous water-tight compartments, &c., and, though called coast defence vessels, there is no protection save the protective deck and coal bunkers.

MISDIRECTED ENERGY IN ELECTRICAL ENGINEERING.

One of the most pertinent remarks in Mr. Preece's recent paper on Mains, was that "It is a pity that some of that redundant mental energy which is endeavouring to raise the efficiency of dynamos and transformers from 94 per cent. to 95 per cent. could not be transferred to the question of mains." There is a curious fascination which leads people to try and make a very good thing still better, and leave a very bad thing alone. This is very noticeable in connection with central station work. If a dynamo gave 1 per cent. lower efficiency than some other, it would be rejected at once, even though mechanically stronger and more likely to be durable; but comparatively little care is devoted to the selection of the boilers and engines. It seems as if very few people could grasp the real significance of a percentage. The differences between the evaporative efficiency of boilers are enormous in comparison with the differences of dynamos. The difference of one pound of water per pound of coal in a station swamps all the differences of full-load efficiencies in the electrical apparatus, yet only one or two engineers go into these matters carefully. It all points to the conclusion that the successful stations will be those designed by engineers, in a broad sense, rather than by electricians, in a narrow sense.

ENGLISH AND AMERICAN MARINE ENGINES.

"Charles W. Wetmore," "E. D. Bartlett," and "A. D. Thompson" are the names, states the *Marine Review*, of Cleveland, that will be given to the three steam barges now on the stocks at the yard of the American Steel Barge Company at Duluth, Minn. Triple-expansion engines, built by the North-Eastern Marine Engineering Company, of Sunderland, and now at the yard at Duluth, will be placed in the "Bartlett," and their efficiency will be compared with that of engines built by Messrs. Hodge, of Detroit, Mich. The cylinders of the Hodge engines are 18in., 30in., and 48in., by 36in. stroke, while the English engines are 17½in., 28in., and 47in., by 33in. stroke. The experiment will, no doubt, attract some attention, but the Detroit builders express no fear regarding the results of the comparison. The cost of the English-built machinery is not definitely known, but it is understood to be slightly under the prices that have ruled on the American lakes.

NEW ALKALI PROCESS.

A process for the manufacture of soda and chlorine presenting some novel features has recently been patented in France by M. Reynaud. Common salt and sulphide of iron are heated together in a stream of air. Sodium sulphate, ferric oxide, and chlorine are produced, the last named being led away and utilised. The solid residue is heated with coal or other form of carbon in a reducing flame, the following reaction occurring:—

$$3Na_2SO_4 + 2Fe_2O_3 + 16C = Fe_4Na_6S_3 + 2CO_2 + 14CO.$$

The product is treated with a mixture of moist air and carbonic acid, giving

$$Fe_4Na_6S_3 + 2CO_2 + O_2 = Fe_4Na_2S_3 + 2Na_2CO_3.$$

The mass is lixiviated, the sodium carbonate removed and recovered by evaporation, while the double sulphide serves to begin the cycle of operations once more, thus

$$Fe_4Na_2S_3 + 4NaCl + 18O = 3Na_2SO_4 + 2Fe_2O_3 + 2Cl_2.$$

FRENCH COMMERCE.

The following figures, taken from the statistics just published by the Customs Administration, give a comparative view of the value of the imports and exports during the first four months of last year and this:—

	1891.	1890.
Imports—		
Alimentary produce	£19,319,880	£18,195,440
Materials used in manufactures	36,987,440	31,241,480
Manufactured articles	8,305,200	7,742,880
Other goods	1,663,360	1,551,920
Totals	£66,275,880	£58,731,720
Exports—		
Alimentary produce	£9,348,120	£10,425,720
Materials used in manufactures	9,329,520	9,317,120
Manufactured articles	24,745,400	25,351,480
Other goods	2,871,400	2,721,200
Totals	£46,294,440	£47,815,520

SIMPLICITY IN ELECTRICAL DISTRIBUTION.

Sir W. Thomson's strong adherence to low-pressure direct supply, even for large towns, is a matter of no small importance. His whole argument is that direct supply is simple and cheap, while high-pressure feeder systems are complicated and expensive. Curiously enough, before Sir William put forward his views at the Institution of Electrical Engineers, Mr. Kapp urged the superiority of the high-pressure feeder system on practically the same grounds. The direct-supply system sounds simple, but is not simple in fact. Putting buried transformers at the points of junction of the feeder and networks does not really increase the complication of a central station, but the direct-current feeder arrangement is only simple outside the station; it involves what physicians call "serious internal complications." In calculating the size by Sir W. Thomson's law, the current densities come out very high, and the full-load drop is also very great, and varies very much with the distance. The result is that parallel running at the stations, and the battery arrangements become enormously troublesome. Moreover, a large town needs several stations, which is a further serious drawback.

WATER GAUGE GLASSES FOR BOILERS.

The fracture of a gauge glass is always an awkward accident, and many devices have been made for automatically cutting off communication with the interior of the boiler when it occurs. But prevention is proverbially better than cure, and a new cause for the failure that happens from time to time has been noted, and means for avoiding it indicated. It has been observed that the upper end of a gauge glass, where it enters the steam-space in the boiler, is sometimes attacked above the packing—being either worn into ridges and grooves, or reduced uniformly in thickness until it is a mere shadow of its former self. No particular harm results from this corrosion when the diameter of the gauge glass is small, but if about ⅜in., fracture is very common when the attack has extended to about half the thickness of the walls of the tube. The lower end of the gauge glass, where it is immersed in water, is not attacked, a circumstance that would lead to the supposition that the steam had some specific action, were it not that at the upper end the glass is attacked only on the outer surface. It is difficult to see why this selective action should take place. The practical solution arrived at, however, consists in allowing the upper end of the gauge glass to project from the packing as little as possible.

GREAT INCREASE IN THE WHEAT TRADE OF BOMBAY.

The Bombay papers record an extraordinary export of wheat from that port during the past few weeks. The *Times of India* says that every warehouse near the docks and every available piece of open ground were occupied by towering tiers of bags filled with grain, awaiting the arrival of ships to take it away to other ports, where abnormal prices have been paid for it. In 1874 the total shipments of wheat from Bombay were 33,071 tons, while in 1886 the figures went up to 617,834 tons, this being the largest total shipped up to the present year. But never since 1874, the year when the wheat trade practically began, have the receipts of wheat in Bombay been so large, or nearly so large, as in the first four months of the current year. They reached during that period the enormous total of 198,097 tons, as compared with 97,420 in the corresponding four months of the previous year, and 178,686 in the same period of 1886. Steamers representing a total carrying capacity of between 350,000 and 400,000 tons were expected to load in Bombay during May; and, in spite of this large carrying accommodation, it will be no easy matter to get the bags, or, at least, those that are not under cover, shipped before the rains. The receipts continue to be so great that as fast as the ground is cleared of one consignment it is occupied by another. The real cause of this unprecedented traffic is the damage sustained by the French wheat crop, which is likely to be about 25 per cent. under the average. The traffic over the different railway systems terminating in Bombay has been gigantic during the past few months. As recently as 1876 wheat was rotting in the Central Provinces, which is now regarded as the granary of India, on account of want of transport; but owing to the railway extensions carried out since that time—the through route to Calcutta being one of the most important—the number of growers has increased materially, and it is now worth their while to produce grain extensively. The lines have been overcrowded with grain, the receipts in Bombay being so vast that the greatest difficulty is experienced in finding warehouse accommodation for the hundreds of tons which are daily brought in from up country. Indeed, the competition for accommodation is so great that the rentals have gone up to more than 100 per cent. beyond the ordinary charges. The price of labour and cost of carting have also increased.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

19th May, 1891.

8500. Roper & Roper ..... Dies for making bricks.
8501. Jones, G. P. ..... Locking attachment for surface boxes.
8506. Stibbe, G. ..... Knitting machines (*Dubied*).
8509. Dutton, E. K. ..... Differential gearing (*Wattles*).
8514. Harding, H. J. ..... The construction of boats and vessels.
8517. Heys, W. E. ..... Automatic time stamps (*Giroud*).
8519. Oakley, W. ..... Middlings purifiers.
8528. Rylands, D. ..... Furnaces for glass melting.
8537. Stern, Horsfall, & Bickham ..... Wire-heald machinery.
8539. Smith, C. H. ..... Rotary sewing machines.
8543. Newton, H. E. ..... Printing machinery (*R. Hoe & Co.*).
8547. Beck, W. H. ..... Production of compressed air and its application (*Morean*).
8569. Meister, E. J. ..... The propulsion of steamships.
8571. Hunt, M. R. ..... Bosh jackets for blast furnaces.
8577. Elliott, G. R. ..... Rifled ordnance and projectiles.
8578. Lake, H. H. ..... Steam boilers (*Tonns, Hall, & Allen*).
8585. Lake, H. H. ..... Vacuum pumps (*Berrenberg & Nickerson*).
8586. Lake, H. H. ..... Self-threading shuttles (*Mason*).

20th May, 1891.

8590. Lindner, E. ..... Turning lathes and chucks.
8591. Thompson, W. P. ..... Delinting cotton seed and grading the lint (*The Knerr O'Brien Cotton Seed Cleaning and Linting Company, Ld.*).
8593. Haynes & Wilcock ..... Bobbins or pirns for yarn.
8597. Haigh, N. N. ..... Wood-sawing machines.
8600. Bradshaw, A. ..... Back pressure valves.
8606. Justice, P. M. ..... Liquid meters (*The Thompson Meter Company*).
8607. Cuttriss, T. ..... Gas engines.
8614. Loosemore, R. F. ..... Motors for driving sewing and like machines.
8617. Chadwick, J. J. ..... Taking-up motion for looms.
8621. Soulby, W. H. ..... Rotary steam engine.
8624. Coppard, J. ..... Machines for mincing meat.
8629. Spencer, W. H. ..... Apparatus for vaporising oils.
8638. Petersen, E. ..... Apparatus for producing draught in steam boilers.
8645. De Michele, V. D. ..... Cranks and discs to obviate dead centres.
8646. Brydone & Chattaway Railway station indicator.
8648. Bazin, E. ..... Producing electric light and cold.
8651. McGlasson, R. ..... Steam boilers and engines.
8652. Nichols & March ..... Gas locomotives.
8654. Horn, W. W. ..... Trueing locomotive wheels (*Elder*).
8657. The Patent Stamped Steel Railway Axle Box Company, Ld., & Donnelly ..... Machinery for the manufacture of axle boxes.

21st May, 1891.

8669. Sheppard & Rispin ..... Couplers for railway carriages.
8670. Sykes, W. R., Sen. ..... Railway signalling apparatus.
8685. Newton, A. V. ..... The construction of ships (*Grimm*).
8687. Vautin, C. T. J. ..... Amalgamator.
8688. Vautin, C. T. J. ..... Extracting gold from ores.
8693. Rinne, H. ..... Flue boilers.
8695. Breyer, J. ..... Safety apparatus for hoists.
8699. Dähne, J. F. G. C. ..... "Trollies" or "bogeys."
8705. Donnelly, J. ..... Gas welding appliances.
8706. Donnelly, J. ..... Buffer guides for railway vehicles.
8707. Capell, G. M. ..... Exhaust and blast fans.

22nd May, 1891.

8711. Doran & Stack ..... Ship elevator.
8728. South & Bursch ..... Car coupling
8731. Mewburn, J. C. ..... Apparatus for moistening air (*See*).
8734. Davies & Fuge ..... Fluid pressure engines.
8737. Williams, R. H. ..... Ploughs.

23rd May, 1891.

8766. Briscoe, J. ..... Single-cylinder compound steam engine.
8769. Clark & Clark ..... Process for the production of armour plates.
8782. Littlewood, M. ..... Bearings for the axles of trollies, trucks, and railway and tramway vehicles.
8785. Meikle, W. ..... Exhaust blast contrivance for steam boilers.
8788. Coombs, E. T. ..... Harrows.
8794. Herbert & Smith ..... Bending or curving metal strips.
8801. Tangyes, Ld., & Williams ..... Locking the screw nuts of screw bolts.
8809. Mirrlees, W. J. ..... Evaporating and distilling apparatus (*Yaryan*).

ELECTRICITY.

19th May, 1891.

8499. Crompton, R. E. B. ..... Apparatus for controlling currents.
8540. Moore & Warren ..... Conductors for railways.
8555. Thompson, W. P. ..... Insulated conductors (*Williams*).
8575. Tesla, N. ..... Methods of and apparatus for generating and utilising electric energy for lighting purposes.

20th May, 1891.

8609. Smith, T. ..... Leads for conductors.

21st May, 1891.

8659. Rowan, A. H. ..... Electric tramroads.
8664. Sigmund, C. ..... Storage cable.
8680. Cox, Robinson, & Gritton ..... Electric lighting of ships' signal lamps.

22nd May, 1891.

8735. Berdoe & Shum ..... Storage batteries.

23rd May, 1891

8784. Evershed & Richards ... Telegraphic signals.
8798. Hanusse & Borrel ..... Signalling apparatus.
8806. Gravier, A. I. ..... Dynamo machines.
8808. Green, W. J. ..... Batteries.
8811. Mengarini, G. ..... Meters.
8812. Hoster, A. ..... Casing for electric wires.

CHEMISTRY.

19th May, 1891.

8510. Pennington, H. ..... Process of manufacturing lead sulphate from metallic lead.
8530. Hedley, G. H. ..... The manufacture of sulphate of soda, hydrochloric acid, and red oxide of iron.
8573. Johnson, J. Y. ..... Hydrocarbon products for insulating purposes (*Weir*).
8574. Vogt, A. ..... Manufacture of carbonate of soda and carbonate of potash.
8584. Riedel, L. F. ..... Manufacture of an iodine derivative of phenacetin.

20th May, 1891.

8641. Chambaud, G. ..... Agglomeration of lignite.

21st May, 1891.

8692. Lyte, F. M. ..... The production of caustic alkalies and other products.
8697. Lobet, L. ..... Carburetting apparatus.
8702. Willcox, B. ..... The production of colouring matters from anthraquinone and alizarine blue (*Farbenfabriken vormals Fried. Bayer & Co.*).

MISCELLANEOUS.

19th May, 1891.

8513. Turnovsky, C. ..... Grate bars.
8529. Bateman, D. C. ..... Hardening and tempering steel wire.
8563. Wagener, V. ..... Safety lamps.
8564. Simpson & The Ixion Company, Ld. ..... Ball bearings.
8565. Andrews, T. L. ..... Locking nuts on bolts.
8583. Hall, R. F. ..... Driving chain.

20th May, 1891.

8608. Fox, C. J. ..... Launching ships' boats.
8611. Hosack, H. H. ..... Ships' boats disengaging gear.

21st May, 1891.

8681. Thompson, W. P. ..... Placing detonating signals on railways (*Elcoate*).
8690. Woakes, E. R. ..... Jointing thin metal pipes.
8698. Lane, H. ..... Indicators for railway carriages.

22nd May, 1891.

8708. Cooper & Wigzell ..... A collision averter or self-projecting sea drag.
8721. Hyde, C. ..... Driving bands for spinning machine spindles.
8736. Defries & Fenny ..... Lamps.
8739. Everson, C. R. ..... Metal roof.
8746. Gougy, F. E. ..... Non-conducting means for steam boilers.

23rd May, 1891.

8771. Read, J. C. C. ..... Air spreaders for argand burners.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1890.

2707. Whipple.
7702. Schon.
7838. Drakin.
8056. Simpson.
8108. Sang.
8675. Oldershaw & Lakin.
8734. Turner.
9404. Mills.
9472. Hardingham (*Felten & Guilleaume*).
9597. Bower.
9651. Lok & Gumhart.
9708. Davies.
9802. Baker.
10187. Thompson (*Stanley & Shallenberger*).
10232. Harding.
10295. Curson.
10297. Abbey.
10363. Hitching.
10432. Lutter, Scholvien, & Riedel.
10448. Brooke, Simpson, & Spiller, Ld., & Green.
10449. Hutton.
10668. Jenner.
10707. Simpson.
10802. Imray (*Farbwerke vormals Meister, Lucius & Brüning*).
10830. Yates (*Boll*).
10872. Thompson (*Yates & Learned*).
10953. Cuffe.
10991. Buckley.
11033. Bennett.
11063. Lake (*The Typewriting Machine Company*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Governor.—*A. B. Collis, Halstead, Essex.*—This is a governor for steam engines, which is not operated by centrifugal action, but which consists, in effect, of a valve so arranged as to be sensitive to variations in the flow of working fluid past it to the engine, and operating to close the supply passage on an increase of flow, or conversely, increasing the opening of the passage in the event of a diminution of flow, as may be understood by reference to the illustration below, which represents one modification of the appliance, in vertical cross section. The disc valve A is mounted to slide freely upon a stem or spindle B, and is arranged within, but does not seat upon, a conical chamber C, through which the steam or other fluid passes to the engine. Steam, for instance, admitted by way of the pipe D to the space E, enters at the large end of the conical chamber, passes round the edge of the disc valve, and escapes at the smaller end of the chamber, through the cylindrical part F, into the pipe G. The pressure of the incoming steam tends to force the valve towards the part F, and thus to diminish the area of the annular passage between the valve and the conical aperture. The movement of the valve is, however, resisted by a spiral spring H, which may be mounted upon the spindle I as shown, and so arranged as to permit of its being adjusted from the exterior of the apparatus. It is preferred

to adjust the spring by causing the spindle I to move longitudinally. In the illustration, the spindle is shown as working through packing in a stuffing-box and gland on the cover of the casing, which is extended downward to form a stop J for limiting the upward movement of the valve A. Part of the spindle is screw-threaded, as shown, and engages with a screw-thread cut in the crossbar K. L is a lock nut for locking the spindle in position. After loosening this lock nut the spindle can be turned by a hand-wheel M to bring the nut N nearer to or further from the valve A, and so increase or diminish the compression in the spring. When the valve A enters the cylindrical aperture F, below the conical opening C, the supply of steam to the engine, except for leakage past the valve A, is entirely cut off. The downward movement of the valve may be limited by the insertion of a grid or of projections in the part C, so that steam may never be entirely shut off by the valve A, sufficient steam to run the engine at a certain predetermined limit of power being always allowed to pass. Instead of a single disc valve, a partially balanced equilibrium valve regulating two steam passages may be employed and controlled by a spring as in the foregoing arrangement, than which, however, it would be much more sensitive. Claims: The valve or valves operated by the rush of steam acting against a spring whose resistance may be conveniently varied, for use as a governor; also the details of the arrangement substantially as described.—No. 7899. May 22nd, 1890. 8*d.*

Automatic Adjustable Bearings.—*D. Abercrombie, Manchester.*—This invention is applicable to the adjustment of the wearing parts of bearings, particularly where the bearings are difficult of access. In applying the invention to the large end of an engine connecting-rod in which the brasses are held together by bolts parallel to the rod, a spur pinion is screwed upon the end of each bolt, each pinion gearing into a toothed ring placed between them. Each pinion bears against the cap of the bearing, and forms the nut for the bolt upon which it is screwed. To the inner side of the toothed ring is secured one end of a coiled spring, the other end of which is connected to a central stud capable of being rotated, so that by turning the stud or boss the spring can be wound up, the tension in the spring being retained by means of a ratchet arrangement. After the first adjustment, whenever wear takes place, there will be sufficient power in the spring to move the toothed ring and thereby slightly turn the pinions, automatically tightening the brasses. This compensation will take place as required by the wear. Equivalent arrangements are shown, applied to individual nuts, and arranged for tightening up cotters. Claims: The use and application of the spring and ratchet as described.—No. 8887. June 9th, 1890. 8*d.*

Rotary Engine.—*J. Griffiths, E. C. James, & J. Hunt, all of Cardiff.*—This is a rotary engine in which variation of the amount of expansion is stated to be provided for, and in which it is sought to diminish friction as far as is possible. The manner in which these results are obtained will now be explained with reference to Fig. 1, which is a sectional elevation of the engine, and to Fig. 2, which is a sectional elevation taken at right angles to Fig. 1. In these views A is the working cylinder, B is a drum carried upon the main shaft C, which latter rotates about a

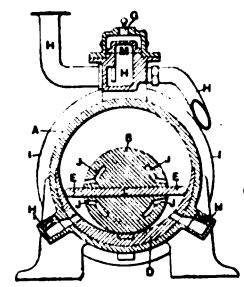

FIG. 1.

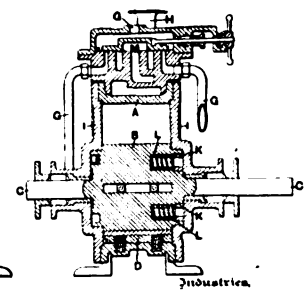

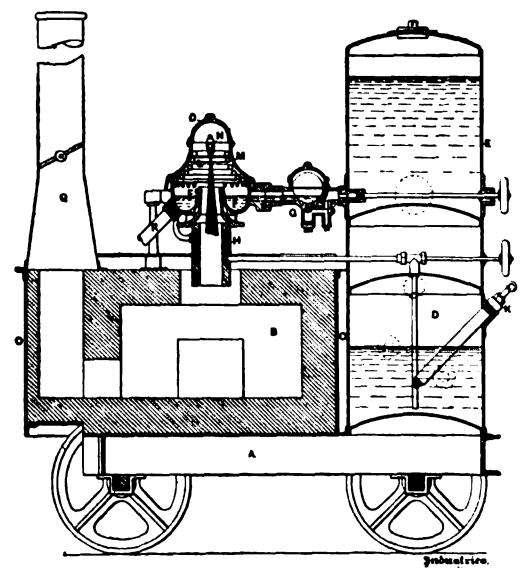

FIG. 2.

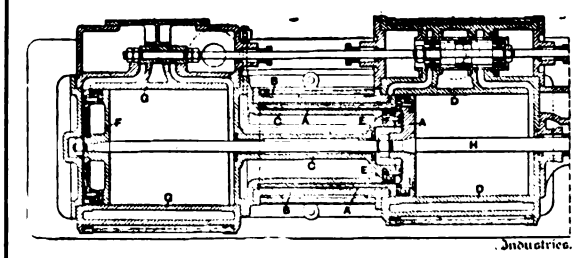

permanent axis eccentric to that of the cylinder, as shown. It may be observed that the position of the drum, relatively to the cylinder, is such that the periphery of the former is always in contact with the latter along a line at the end of the shortest diameter of the cylinder. A packing piece D, of an inverted saddle or crescent shape, is fitted in the cylinder A, and causes the cross section of the cylinder to be approximately elliptical. E E are the pistons, and they, as well as the packing piece D, are provided with suitable packing strips F. Springs are inserted between the pistons to keep their outer ends in touch with the face of the cylinder. In consequence of the form of the cross-section of the cylinder, no cams are required to keep the pistons in contact therewith, and the inventors esteem this an important feature of their improvements. The supply of steam to the engine enters by the pipe G and exhausts by the pipes H. The steam enters through ports in the cylinder covers I and flows into the respective ports J in the drum. A ring K lies in an annular groove in the face of the drum, and is provided with springs L adapted to press it against the adjacent cylinder cover to make a steam-tight joint therewith. Radial tough pieces are provided to prevent the ring from revolving in its recess, and also serving to prevent the steam from passing across the ends of the drum and distributing itself into the wrong portion of the cylinder. The engine is governed by a reversing valve M, which causes the steam to pass through one or other pair of the steam and exhaust passages, which are duplicated; and the amount of expansion the inventors state is "governed by the length of the ports J; the longer they are, the further is the steam carried into the cylinder; while, on the other hand, shortening them leads to the cut-off being effected at a correspondingly earlier point in a revolution." Claims: The combination of cylinder, inverted saddle piece, drum, and radial pistons; the combination of cylinder elliptical in cross-section, revolving drum, and "arrangement of ports adapted to render the amount of expansion variable, according to the lengths of the respective ports, as set forth;" the whole arrangement as a combination.—No. 2569. February 12th, 1891. 6*d.*

Oil Flame Furnace.—*The Lucigen Light Co. & T. M. Jarmain, London.*—This invention relates to a furnace in which heat is produced by an oil flame directed by a steam jet. The furnace may be either stationary or portable. The portable furnace is constructed as shown in the accompanying illustration,

which is a longitudinal section. On a wheeled truck A is a furnace chamber B, of fire-brick or other suitable refractory material, preferably strengthened by a metal casing C, and at the side of this structure, separate from it, is placed a tank D containing water and compressed air, and above it a tank E containing oil. Over the furnace chamber is fixed the burner, which is of the following description:—A basin F, having a tubular boss F¹ projecting up from its centre, is supplied from the oil tank E with oil up to a certain level determined by a suitable float valve. Below the basin is a closed annular vessel H constituting a boiler supplied with water from the water tank D, subject to the pressure of air in that tank produced by a hand force pump K or otherwise. From the annular boiler H a pipe extends upwards, and after being carried in the form of a hollow coil L above the basin it terminates in a nozzle N directed downwards towards the centre of the basin. The coil L is enclosed by a metal casing M covered by a cap O. Within the boss F¹ of the basin, and within the boiler H, there are refractory linings to protect those parts from excessive heat. For putting the burner into action the cap O is removed, the oil in the basin F is kindled, and the flame burning upwards, heats the coil K until steam is generated. The steam issuing from the nozzle N then directs the flame down through the tubular boss F¹, and the water supplied to the annular boiler H is converted into steam, which, becoming superheated by passing through the coil L, issues from the nozzle N in a powerful jet directed downwards. The cap O being replaced, air drawn in by the injector action of the jet through the holes of the cap and through slots round the edge of the basin, mixes with the oil vapour evolved from the oil in the basin, and forms a flame directed downwards into the furnace chamber B, so as to heat crucibles, rivets, or other articles placed therein. The products of combustion pass upwards by the chimney Q. By means of a pipe R provided with a valve or stopcock the basin can be emptied, the flame being thus extinguished. For a stationary furnace the burner is like that above described and acts in the same manner, but the water and oil tanks may be arranged where convenient, the oil tank being at a level sufficiently high to supply the basin of the burner. Claims: An oil flame furnace constructed and operated substantially as described with reference to the accompanying illustrations.—No. 9181. June 13th, 1890. 6*d.*

Engines and Pumps.—*H. G. Holborow, Stonehouse, Gloucester.*—The improvements hereinafter described are particularly applicable to motor engines of the compound and triple-expansion types, the objects aimed at being simplicity, compactness, and accessibility, together with moderate prime cost. The improvements are applicable also to pumps. The nature of the invention may be readily gathered from the horizontal section below of a portion of a stationary engine of the triple-expansion type constructed according to this invention. A is a trunk piston, which works within a cylinder B, and upon the exterior of a fixed trunk C, the cylinder B, as also the trunk C, being arranged concentrically with the cylinder D. The outer extremity of the trunk C is packed at E, as shown, and the piston A, against

which the trunk packing works, is similarly packed in the cylinder D. The piston rod H is connected to the solid face of the hollow piston A. The construction thus far is applicable for use as a compound engine, the live steam being primarily admitted to the annular face of the hollow piston A, and subsequently conveyed to the opposite or disc-like face of the same piston. The cylinder D is steam-jacketed, and live steam is admitted for heating purposes to the interior of the hollow trunk C. Any steam or water which may leak past the packing E passes through a passage in the trunk C to the interior of the hollow piston, whence it may be withdrawn. For triple expansion a final or low-pressure cylinder is added, either tandem or parallel with the first. The tandem arrangement is shown herewith. As before explained, the annular face of the piston A is exposed to the high-pressure steam and is single-acting. The opposite face of the same piston serves as a single-acting intermediate piston. The low-pressure piston F is enclosed in a second cylinder G, and is double-acting, and also, by preference, steam-jacketed. Any convenient valve gear may be employed. The application of this invention to a "bucket and plunger" pump is described, in which, rigidly connected with the bucket, is a hollow plunger, which works on the exterior of a fixed trunk, and is enclosed within a barrel, the latter being formed as a continuation of the pump barrel, and enclosing the fixed trunk aforesaid. Claims: In a motor engine working on the compound or triple-expansion systems, the employment of a trunk piston the trunk of which works upon a fixed trunk, which it fits, and working freely within the high-pressure cylinder, whilst the body of the piston works in and fits the low-pressure cylinder; the arrangement of parts (including particularly the arrangement of packing) as described and shown; the employment of the piston and hollow trunk, the latter fitting a fixed trunk, for pumps, as shown, whereby the packing of the working parts is facilitated.—No. 6919. May 5th, 1890. 11*d.*

Keys for Railway Rails.—*H. H. Lake, London.* (*Paul Espinasse, Montclar de Quercy, France.*)—A metallic wedge or key for securing the rails of railways in their chairs is formed of a single piece of steel of definite length, this plate being bent several times upon itself in a special manner in order to form an elastic body, and being provided with stops to prevent it from being displaced when once it is driven into its place. The bending is effected in such a manner that between the two parallel sides of the wedge, when it is in place, one of the extremities of the plate presents the form of an S, and will bear upon the interior side placed against the rail, whilst the straight part of the exterior side is placed against the chair, its length corresponding to the width of the latter. The extremity of this exterior side is provided with a bend, so as to form a stop bearing against one side of the chair, and on the other side of the chair a second larger bend is formed, which terminates in the interior side bearing against the rail. For enabling the insertion of the wedge to take place, the side bearing against the rail is inclined, when the key is free or expanded, so that the key can

Digitized by Google

be placed by hand in readiness for forcing into place, which is effected by a strong jack. A modification is shown, which is capable of being introduced vertically into place, the curved strip forming an elongated eye with one fold overlapping and being left straight; two snugs project from the two sides of the straight arm, and embrace the edges of the jaw of the chair, when the key is forced into place by a suitably formed lever. Claims: The elastic keys, with stops or snugs as described.—No. 7884. May 20th, 1890. 8*d*.

MANUFACTURE OF GLASSWARE.—*D. Rylands, Stairfoot, Barnsley.*—Improved machinery for the manufacture of bottles and other glassware is described, together with improvements in the processes of working the same. One of the objects of the invention is the better regulation of the pressure of the plunger

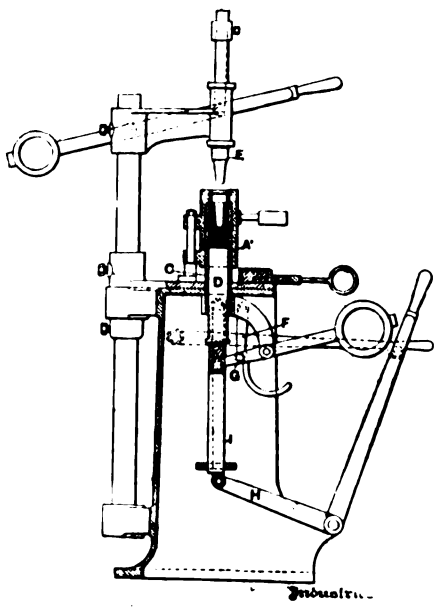

FIG. 1.

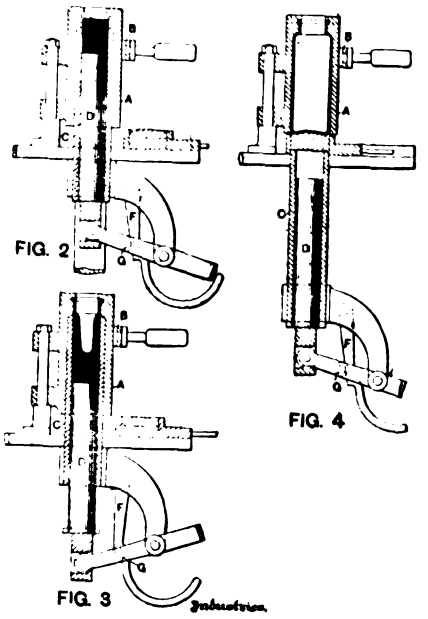
used in first pressing the molten glass into the required shape in readiness for the blowing out of the glassware to its full size, another object being that the pressing or parison mould shall be kept at the heat most favourable for securing the best output. The improvements are applicable to fixed, rotary, or radial machines, and the parison mould may be worked top downwards as well as upwards. Fig. 1 is an elevation partly in section, and Figs. 2, 3, and 4 are sectional elevations, of the mould and mould table. The apparatus and mode of operation are as follows:—The blowing mould A being closed and locked by a catch lever B, the parison mould C and the moveable parison mould bottom D being in the position shown in Fig. 2, molten glass is charged into the cavity contained in the upper portion of the parison and blowing moulds, and, the pressing plunger E descending, causes the molten metal to ascend and occupy the space formed in the upper portion of the blowing mould, thus completing the neck and mouth of the bottle or other article. The plunger E in its descent having closed the opening in the upper portion of the mould A, will cause the descent of the moveable mould bottom D, which will then occupy the position shown in Fig. 3, when the



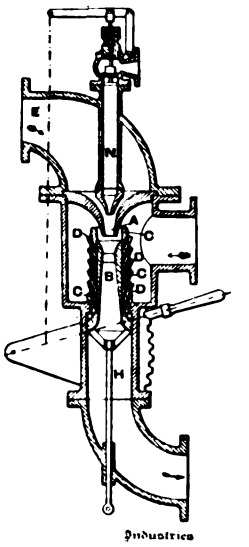


FIG. 2

FIG. 4

FIG. 3

detent lever F will have latched itself on to stud G, thus preventing the ascent of the moveable mould bottom upon the re-ascent of the pressing plunger. The sliding pressing mould being now, by lever H and link I, withdrawn from the blowing mould (sliding down upon the blowing mould bottom), the parison mould C is again raised, lifting with it the blowing mould bottom, into the position shown by Fig. 4. A blowing attachment, not shown in the illustrations, but carried by the pressing ram, descends and closes the mouth of the blowing mould. Air under pressure being then admitted, will cause the parison, as shown in Fig. 3, to expand and assume the completed form as in Fig. 4. It will be seen that the pressing mould bottom D, being counterpoised, will prevent any undue pressure being applied by the plunger to the molten metal, and, as a consequence, the bottles or other articles will be free from marks or other defects. Also, the molten glass being charged into the upper portion of the combined mould, the glass will not have far to ascend before the neck of the bottle is formed, and, the after formation being from the top downwards, prevents any violent plunger action on the molten material. To ensure the blowing mould being at a suitable temperature, any convenient number of separate parison moulds may be employed, disposed radially round the main pillar of the machine, the blowing mould bottom being capable of being moved radially round the centre pillar to come over any one of the parison moulds, the one last used being cooled whilst the next mould is in use. Another modification is shown in the specification, differing slightly in arrangement, but operating upon the same principle. Claims: In the manufacture of machine-made bottles, regulating, by counterbalancing the parison moulds, the pressure exerted on the molten glass during manufacture; the arrangements whereby one blowing mould can be worked in conjunction with two or more parison moulds; claims also the particular arrangement and combination of parts described.—No. 7145. May 8th, 1890. 8*d*.

EJECTOR CONDENSERS.—*O. Lindemann, London.*—This invention has for its object the variation of the length of the water jet in an ejector condenser by means of a moveable receiving or combining nozzle which will simultaneously increase or decrease the distance between the mouth of the water nozzle and the throat of the receiving nozzle. The inlets for steam to the interior of the condensing tube are arranged over the whole length of that tube in such a way that when the receiving nozzle is moved within the condensing tube a greater or lesser number of the steam inlets are covered and put out of action. Thus the capacity of the condenser is variable, and the variation is said not to influence the vacuum to any great extent. The receiving nozzle may be moved by hand, or should the engine to which the condenser is applied be worked under a variable load, the receiving nozzle may be moved automatically in accordance with the variations of working. Where a supplementary or starting jet is employed, the actuating arm thereof is so connected with the gear for moving the receiving nozzle that as the receiving nozzle is raised the aperture of the starting jet is opened, and *vice versâ*. The accompanying illustration represents in section an ejector condenser

with moveable receiving nozzle, and a nozzle for the admission of a starting jet, or jet of high-pressure liquid or fluid, arranged in the centre of the water nozzle. In this view A is the water nozzle, B the receiving nozzle, and C the condensing tube with the steam apertures D distributed over its surface. The receiving nozzle is fitted with a cross piece, which is connected to the rod H, which passes to the exterior of the apparatus, and by means of which the receiving nozzle B can be moved, either by hand or automatically. E is the water supply pipe, and N the nozzle for high-pressure fluid, within the water nozzle A, with a valve which by suitable connection is operated simultaneously with the movement of the receiving nozzle as before described. Claims: In water jet or ejector condensers a receiving nozzle moveable from the outside, and fitting into a cylindrical condensing tube as described so as to operate as a regulating valve; the connection of the arrangement for moving the adjustable receiving nozzle with the valve for shutting off the pressure fluid, the one opening or increasing while the other operates reversely, as described.—No. 4165. March 9th, 1891. 6*d*.

SCREW BOLTS AND NUTS.—*H. H. Lake, London.* (*C. Higbee, Philadelphia, Penna., U.S.A.*).—It is desired to include all threaded coupling devices, as well as the two named above. In threaded couplings of all kinds the thread is usually turned in or on a cylindrical or annular part prepared to receive it, and at the end of this part the thread merges gradually into the face of the article, which is usually in a plane at right angles to the centre of the thread. Thus the end of the thread is for some distance very thin, and is by no means symmetrical to the axis of the thread, the consequence being that the two parts of the screw union are frequently put together wrongly, cramping and binding the parts and injuring the threads. To overcome these defects the inventor terminates the thread below the face level of the cylinder or annulus on which it is formed, and he forms the extreme end of the thread so that it is stopped off sharply, and has a broad blunt face lying symmetrically on each side of the centre line of thread. A plain cylindrical portion extends from the finish of the thread to the face of the article. It is recommended that both the male and female threads be formed in this manner, but an improvement is observed if one of the threads be of the usual construction and the other of the improved construction. The inventor believes the broad principle of the device to be original with him, and therefore claims: The improved arrangement of thread with cylindrical finishing portion, where such is used upon one or upon both members of a thread coupling.—No. 4261. March 10th, 1891. 6*d*.

CYLINDRICAL SLIDE VALVES.—*H. Turner, Hoylake, Chester, & W. & T. D. Bayliff, Birkenhead.*—The object of the arrangement described in detail below is to secure and combine the advantages of the ordinary slide and piston valve, whilst eliminating their individual disadvantages. According to this invention as applied to steam engines, the steam distribution valves are constructed of a plurality of portions having a number of faces, the cylinder port face being arranged to correspond. Between the portions of the valves, at their backs, are wedge devices, so arranged that steam is kept off the valve portions, while the wedges themselves are kept up to their work by steam pressure. The waste of steam resulting from worn rings is obviated, and the automatic compensation for wear as in the case of flat slides is secured, the valve being substantially an interrupted piston valve. Fig. 2 below illustrates in sectional elevation a valve casing and cylinder ports, and Fig. 1 is a section through the valve upon the centre line. It will be seen that the valve is composed of four distinct parts, all of which are identical, and which are lettered A B C D. In Fig. 2 half of the portions B and C are shown in section with the wedges. E is the cylinder valve face, having port passages F for the admission of steam, and passages G for exhaust. H H are the steam admission ports, I being the exhaust port. The wedges J are arranged back to back, and bear upon and work in correspondingly shaped recesses in the different portions of the valve, these recesses being carried from end to end of the valve, and being therefore in free communication with the interior of the valve casing, and thus the steam has free access to the spaces K between the bases of the wedges J. In the inclined faces of the wedges, recesses L are provided, which are in communication with the exhaust passage M of the valve sections by way of passages N. By thus having the surfaces covered by the spaces L in communication with the exhaust, the pressure acting upon the bases of the wedges is always equivalent to the difference of pressure between that in the valve casing and that in the exhaust. Springs O keep the valves normally against their bearing surfaces. The wedges are kept in place by the plates P which are bolted to the valve sections, the said sections being themselves kept in place by the ordinary attachments of the valve spindle to the valve. The only pressure acting upon the different valve sections and tending to press them on to the valve face is that due to the action of the steam upon the bases of the wedges, and that which acts upon the small portion of the valve not covered by the wedges. Upon the amount of inclination given to the wedges depends the pressure upon the backs of the valve sections. In another modification, the different valve sections are separate from the portion of the valve which is connected to the valve spindle, and the arrangement of wedges is somewhat different, the principle of the appliance remaining the same. Claims: A valve composed of a plurality of parts, each portion being free to adjust itself, and having a certain limited pressure of steam tending to force each section on to its working face; the arrangments of wedges for the purpose described; the two valves as illustrated in the specification, of which the illustrations herewith show one example.—No. 6285. April 25th, 1890. 8*d*.

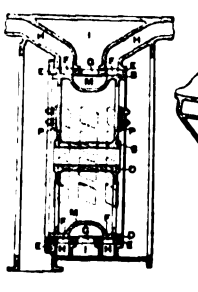

FIG. 1.

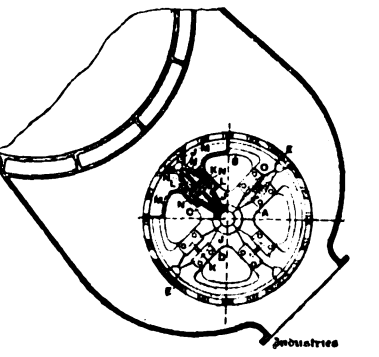

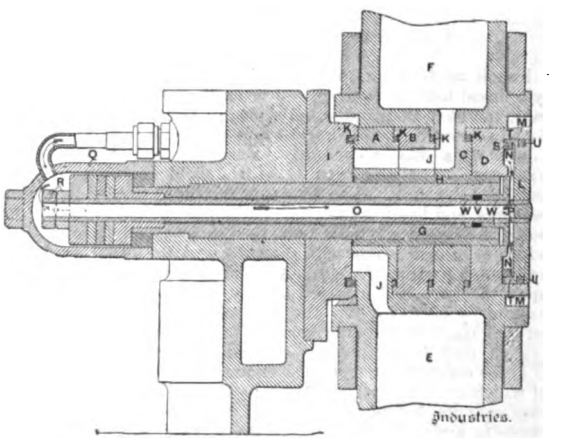

FIG. 2.

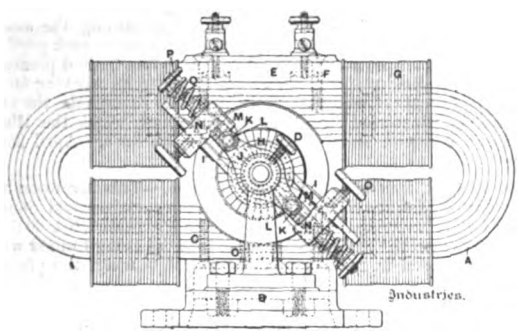
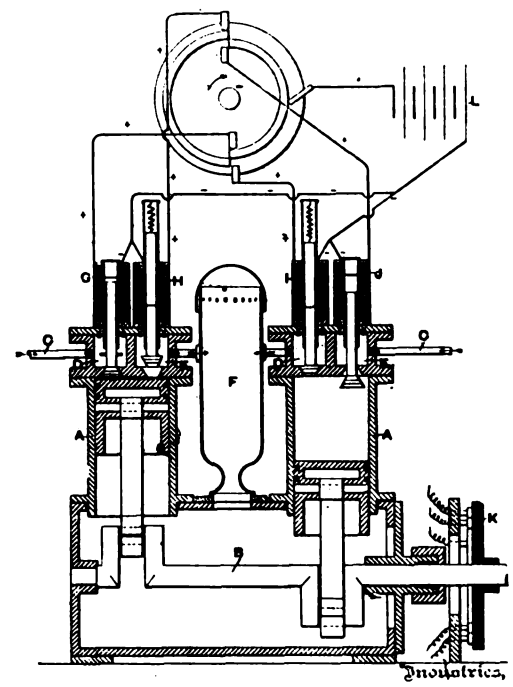
ROTARY ENGINES.—*C. H. Brain, London.*—This invention has reference to improvements in fluid pressure engines and pumps of the kind described in Mr. Arthur Rigg's patent No. 6047 of 1885, in which the cylinders are described as being formed with bosses mounted to revolve upon a central bearing, the pistons



of the said cylinders being connected to a wheel or disc mounted to revolve about an axis out of line with that about which the cylinders rotate. In such engines the inlet and exhaust ports are formed in the cylinder bosses, which work against a faced side cheek provided with corresponding passages. The bosses of the cylinders rotate between the valve and a flange or plate which is fixed to the pin or bearing upon which the cylinders rotate, and the mode of adjustment is such that excessive friction

Digitized by Google

is set up, and injurious wear and leakage result. To obviate these disadvantages is the object of the present invention, which is described with reference to the accompanying illustration, which shows so much of a four-cylinder engine of the kind referred to as is necessary to an understanding of the following description:—A, B, C, and D are the bosses of the four cylinders; only parts of two of these cylinders, viz., E and F, are shown. G is the stud or bearing about which the cylinders revolve, which is surrounded by a sleeve H fixed to the boss A so as to revolve therewith. Upon this sleeve the other bosses oscillate during the working of the engine. The valve I is formed with the usual passages, and against its inner faced side the boss A rotates. The passages J J, in the boss, serve alternately for the admission and exhaust of steam to the corresponding cylinder. The packing rings K are placed between the valve and the adjacent boss, and also between the other bosses, all the foregoing parts being arranged as is usual in these engines. The disc or piston L fits within a short cylinder M, formed at the outer side of the boss B; this short cylinder forms, in conjunction with the boss and the disc or piston, an annular steam space or chamber N. The disc or piston L is fixed upon a tube O, that passes through the stud or bearing G, and is in communication at one end by holes P with the steam space N, and at the other end, by a bonnet or chamber Q, with the steam supply pipe of the engine. Nuts R limit the movement to the right of the tube O and disc L. A packing ring S is located between the disc L and the boss D, this ring, when the engine is in action, being pressed by the steam in the chamber N against the face of the boss D and against the rim T of the disc or piston L. A packing ring U is placed between the disc L and cylinder M, and other packing material V forms a tight joint between the stud or bearing G and the tube O. W is a gland that automatically compresses the packing material V against the ring, by the action upon it of the steam admitted to the space or chamber N. The area of the boss A subjected to pressure of steam within the space or chamber N is such, that when the engine is working, the pressure of steam tending to force the bosses towards the valve I is in excess of that tending to drive them in the opposite direction, and which is due to the pressure on the valve I of the steam within the passages J of the respective cylinders. The difference in the two pressures may be a predetermined one, such as to prevent escape of steam between the two surfaces in contact, whilst also obviating excessive friction and wear. It is preferred, as before stated, to place the tube O in communication with the steam supply pipe, as then the difference between the two pressures mentioned will remain constant, notwithstanding variations in the pressure of steam supplied. Claims: In a fluid pressure engine (or pump) of the kind referred to, subjecting the bosses of the cylinders to the pressure of fluid acting in an opposite direction to and of greater amount than that tending to move the bosses away from the valve, for the purpose specified; constructing an engine (or pump) of the kind referred to with a closed steam space or chamber, one side of which is formed by that cylinder boss which is farthest from the valve, the said space or chamber being in communication with a source of fluid pressure.—No. 2338. February 9th, 1891. 8*d*.



ELECTRICITY.

Dynamos and Motors.—*E. Sechehaye, London.*—The inventor constructs the field magnets of horseshoe form, as shown in the side elevation below, the ends of the limbs abutting against each other. These magnets A A are built up of a series of bent plates fitting closely together and secured together by rivets, the two cores being fixed to the base B by screws C. The abutting ends of the limbs are bored out to receive the cylinder armature D, the several plates of the cores being made, by preference, of such

a length as to form, when fixed together, approximately the cylindrical hollow required, and when the cores are fixed to the base, and have their upper limbs firmly tied together by a plate E and screws F, the cylindrical hollows are accurately turned in a lathe to a diameter slightly exceeding that of the armature windings. The windings G of the field magnets are of the usual construction. The armature spindle is carried in pedestal bearings, and has fixed upon it the armature core, which is composed, firstly, of a tubular part, having two end flanges, one of which is formed in one with the tube, and the other screwed on a threaded portion thereof. A number of iron discs are placed upon the tube, and clamped closely together between the two flanges by screwing up the moveable flange. Any suitable form of armature winding, such as the "Von Hefner-Alteneck" system, may be adopted, or a Gramme ring may be employed. H is the commutator and I the commutator brushes, the holders of which are arranged as follows:—Upon the neck of the armature spindle bearing is mounted the rotatable carrier J, the opposite arms of which terminate in two split clasps K, lined with insulating material and receiving the spindles L, which are nipped tightly therein by means of screws M, when they have been adjusted in position. The spindles L are bent up at right angles, and upon the radial portions so provided are fitted loosely the brush holders P, in which the brushes I are secured by means of screws O. On the screw-threaded outer ends of the spindles L are fitted screw nuts P, and between these and the brush holders are interposed helical springs Q, adjustable to press the brushes with greater or less force upon the commutator. On the spindles L are fixed pins, bent up so as to be parallel thereto, which pins enter holes of somewhat larger size in the brush holders, so that the pins hold the brush holders in position upon the spindle with a sufficient amount of play to allow the brushes I to adjust themselves to the surface of the commutator, so as to obtain perfect contact. When the machine is not in use, the brushes are held out of contact by drawing back their holders against the action of their springs Q until they are free of the pins, and then turning them round until the pins bear with their ends in small recesses U in the end surfaces of the holders, thus holding the brushes securely out of contact. The spindles L being securely held in the split nipping sockets K, the screw nuts and lock nuts on the outer ends thereof, such as are usually employed for fixing them, are dispensed with, and, consequently, as the ends of the spindles can pass closely behind the standards of the bearing, the length of the machine can be reduced to an extent corresponding to the height of such nuts. Claims: Constructing the field magnet cores of dynamos and electromotors of a series of plates bent successively over each other in horseshoe form, the ends of two such horseshoe cores being made to butt against each other, and being secured in position by screws, rivets, or other fastenings, so as to form a closed loop, the inner part of which is cut so as to form circular hollows for receiving the armature; the armature consisting of discs threaded upon a tubular attachment to the spindle, and secured thereon between two end flanges; the brush gear as described.—No. 7981. May 22nd, 1890. 11*d*.

Air Pumps.—*A. J. Boult, London.* (*A. L. Reinmann, A. A. Dittmar, & H. Falkenhausen, all of New York, U.S.A.*)—This invention consists of an air pump in which the suction and discharge valves are actuated by electricity. The illustration below shows an air

exhausting pump in vertical section, the upper part of the figure showing diagrammatically the arrangement of switch and electrical connections. The pump cylinders A each contain a single-acting piston, the two pistons being connected by connecting-rods to cranks set at 180° apart on the crank-shaft B, which receives motion from any convenient source of power. At the top end of each cylinder is fixed a chamber, subdivided by a central partition, and containing in one subdivision a suction valve, and in the other a delivery valve. The suction pipes C, to which the vessel or vessels to be evacuated are connected, enter the two compartments D, and the delivery pipes are led from the compartments E to a trap cylinder F, whence the air passes into the engine casing and so into the atmosphere. Each compartment D contains a mitre suction valve, the compartments E containing similar delivery valves, which open, of course, in an opposite direction to the suction valves. All the valves have their bodies or pistons divided, and suitable packing is inserted in the division so that the valves may make air-tight joints with their seatings. G, H, I, and J are hollow cylindrical electromagnets placed upon the top plates of the chambers D and E. The cores of these electromagnets form valve-stems for the suction and delivery valves. To the top portions of the electromagnets G and H are secured vertical guide casings in which the valve-stems of the delivery valves are suspended by means of springs. The stems of the suction valves are provided with stops, which prevent the valves from dropping too far into the cylinders. These valve-stems or cores have their upper portions made of soft iron, but their lower portions are of brass, so that they may not be magnetised and thus affect the iron portions of the pump. K is an electric commutator or contact maker of hard rubber or other non-conductor mounted on the crank-shaft and rotating therewith. Semi-annular conducting strips are secured to the disc in the positions shown in the diagram at the upper part of the figure, and current from the battery L energises the pair of electromagnets I J alternately with the pair G H, the magnets raising the suction and delivery valves of one pump, whilst the stems of the valves of the other pump are demagnetised and fall into the working position by gravity. In the figure the magnets I and J are just about to be energised, whilst the magnets G and H are just about to be cut out of circuit. The opening and closing of the respective valves is performed simultaneously with the completion of the strokes of the pistons, and the use of complex mechanism for operating the valves is avoided. Claims: An air pump with commutator disc on the crank-shaft regulating the supply of current to electromagnets operating the suction and delivery valves substantially as described.—No. 4403. March 11th, 1891. 8*d*.

CHEMISTRY.

Converting Lead Compounds into Basic Salt.—*J. N. Zeitler, Cannstatt, Germany.*—This invention has for its particular purpose to advantageously utilise the sulphate of lead occurring as main bye-product in the manufacture of acetate of aluminium from alum and acetate of lead, or of acetic acid from acetate of lead and sulphuric acid, in calico printing, &c., for the production of white lead. After determining the quantity of lead contained in the mostly plumbiferous product to be treated, the quantity of carbonate of sodium is ascertained which is required for converting the respective lead compounds—in most cases sulphate of lead—into neutral carbonate of lead, which is done by heating for some time the products to be treated for white-lead—waste products or other compounds of lead, for instance, chloride of lead, nitrates of lead—with the requisite quantity of carbonate of sodium to about 60° to 110° Centigrade. After this operation all compounds of lead have been converted into neutral carbonate of lead. The latter is allowed to subside, and subsequently the liquid above it removed. The carbonate of lead obtained as described corresponds neither in properties nor in composition to white-lead. It is consequently necessary to convert the neutral carbonate of lead into basic carbonate of lead. This purpose is accomplished by boiling the neutral carbonate of lead obtained as described, for some time, with a certain quantity of soda lye, whereby part of the carbonic acid is separated from the neutral carbonate of lead, which is consequently converted into basic carbonate of lead (white-lead). The reaction takes place after the formula:

$$3PbCO_3 + 2NaOH = 2PbCO_3Pb(OH)_2 + Na_2CO_3.$$

The white-lead is left to subside, and after drawing off the sodium solution above it, which can be used for further operations, washed and dried. Claims: The process for converting carbonate of lead into basic salt (white-lead), consisting in treating the carbonate of lead with the requisite quantity of caustic alkali lye.—No. 2812. February 16th, 1891. 4*d*.

MISCELLANEOUS.

Small Arms.—*T. Perkes, London.*—This invention relates to that class of breechloading small arms known as "ejector guns," and its objects are to facilitate the closing of the gun, and to render the mechanism more compact. Hitherto considerable difficulty has been experienced when closing such guns owing to the pressure required to cock the ejecting mechanism when closing the breech. To obviate this difficulty the fore end of the gun is fitted with a rebounding lever, which is operated when the ejecting mechanism is brought into play, either by the ejecting spring or by a special spring. The rebounding lever is held in a neutral position by a catch, and is furnished with a projection which, when the lever is released from the catch, comes into contact with its operating spring, which causes it to rebound after operating the extractor, and thus imparts a return action to the ejector operating mechanism and so allows the gun to be closed with greater ease than heretofore. The catch is fitted with a catch spring whereby it is operated—or the catch may be dispensed with, and the spring itself be formed to act as a catch. The rear end of the catch is prolonged so that it engages with a rod, slide, or lever, or with an extension of the mainspring, any of which are operated by the gun lock mechanism in any convenient manner. Claims: The mechanism to cause a rebound or return action of the ejecting mechanism, to facilitate the closing of the gun. The arrangement of mechanism described for this purpose, to ensure compactness.—No. 2784. February 16th 1889. 8*d*.

Boat-lowering Gear.—*W. Armstrong, West Hartlepool.*—To enable boats to be lowered from a ship and detached from the lowering tackles with facility special davits are supported on pins carried by sockets or double eyes provided on the deck, so as to enable the said davits to swing over the ship's side, by the action of gravity, to a sufficient extent to suspend the boat quite clear of the side. The proper working of the davits is provided for, and sideward motion prevented, by guides formed in beams erected over the deck, and on which the boat's keel rests when the boat is housed. The davits are on the inboard side of the boat, and may be curved to fit the boat if desired, being extended to a suitable height above the boat and inclined sufficiently beyond its centre line to cause it to swing out from the davits when free. Spindles extend between the davits, and are furnished with rollers, from which the lowering tackle unwinds as the boat descends, and with regulating tackle controlled from the boat consisting of a sprocket wheel taking a hand regulating chain and being carried on a shaft which carries also a pinion gearing with a wheel upon the spindle carrying the lowering rollers above referred to. The detaching gear consists of a pair of balanced slip hooks, one at each end of the boat, both hooks being released, when necessary, by a pair of lines led to the centre of the boat, and operating to draw the hooks out of eyes at the ends of the falls, the balance weights causing the hooks, after operation, to resume a position in which they are ready to re-engage. Or the hooks may be unbalanced, so as to fall over upon their backs when relieved of the pull of the tackles upon them. Claims: The general arrangement of boat-lowering and detaching gear as described; the davits constructed to raise the boats from the chocks and to swing the boat clear of the ship's side by the action of gravity; the use of the two modifications of detaching gear as described.—No. 6307. April 25th, 1890. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

SMALL SCREW CUTTING LATHE.

THE accompanying engraving represents a handy little screw-cutting lathe suitable for light work, made by Messrs. Lister & Co., Keighley. The lathe has a 5ft. bed and 5in. centres. A novelty in connection with this tool is the front slide, which is capable of vertical adjustment by a hand-wheel and screw, and which carries the swivel tool rest. The top tool slide may be taken away, leaving a swivel slide with T slots, which may be used for a variety of work, such as light milling, boring, &c. The machine will no doubt be found useful in the cycle trade, or in small shops where a large stock of tools are not available.

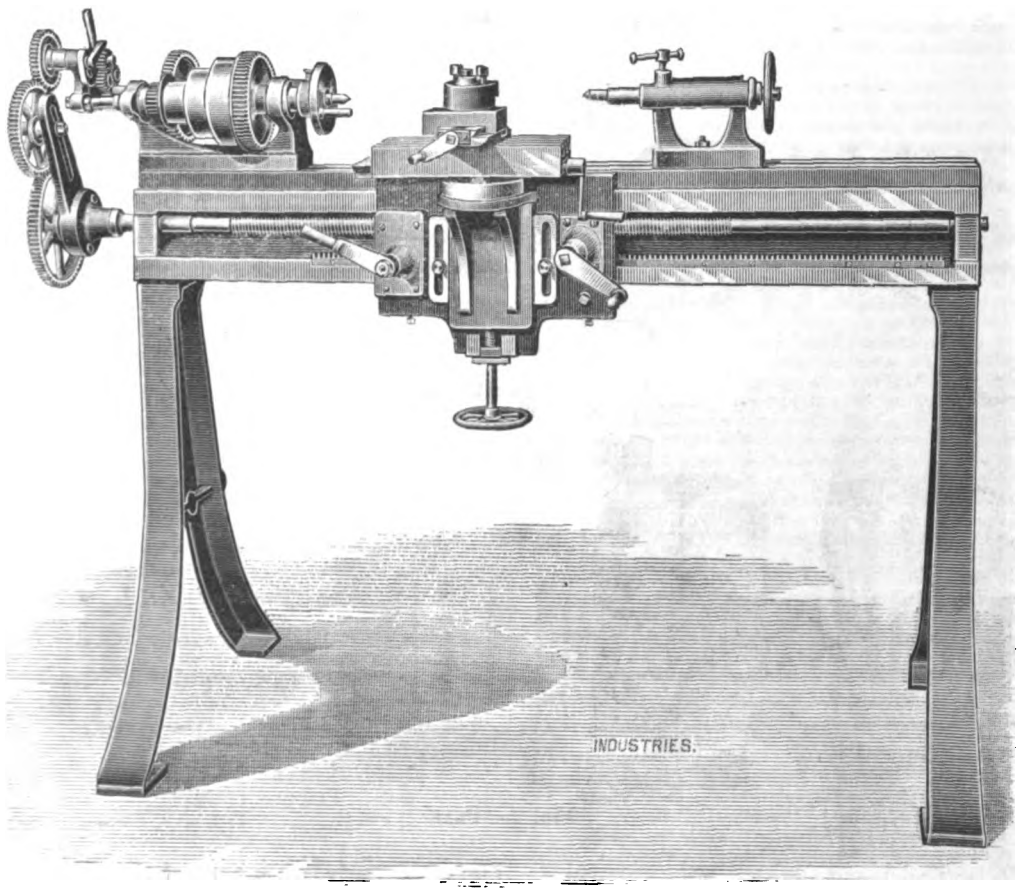
PORTLAND CEMENT SPECIFICATIONS.

I.

THE great variations naturally occurring in the quality of Portland cement, as well as the elasticity of the name itself, have compelled makers and users to adopt some form of specification whereby to judge the commodity in which they deal.

Until quite recently it has been tacitly assumed that the words "Portland cement" had a perfectly definite meaning, and that, though the material thus designated might vary within wide limits, yet there was little fear of the name being appropriated for a product wholly different. This assumption has scarcely sufficient basis to warrant its acceptance, for it is by no means easy to define Portland cement in a way which shall satisfy the primary requirements of a good definition—viz., that it shall include all varieties of the thing defined, while excluding all imitations, however close. In view of the fact that it has been seriously proposed to manufacture and sell cement made from blast furnace slag as Portland cement, a satisfactory definition is by no means a superfluity, and, pending the publication of that which appears to us least open to objection, we should be glad to gather from those of our readers conversant with the subject a consensus of opinion on the question, "How should Portland cement be defined?"

Since, then, the very name of the material with which we are dealing is far from precise in its significance, it is by no means surprising to find that equal dubiety exists as to the properties which it should possess. Divergence of opinion first appears, as might be expected, among users the necessities of whose work make them exacting in their demands, and insistent upon the satisfaction of those demands, as they are proportionately more alive to small differences than are others less critical. It is among engineers entrusted with the supervision of the erection of permanent and costly structures that one finds that intimate knowledge leading to what might be termed hypercriticism of the materials they use—a knowledge and power of discrimination that find expression in the specifications they adopt. These divergences of opinion, exemplified by corresponding variations in specifications of different origins, may be traced as arising from differences in the requirements of the users, the extent of their familiarity with the nature and properties of the material they use, their acquaintance with the exigencies of manufacture, and, lastly, from their professional idiosyncrasies. The final cause here indicated may be scouted as being, as it should be, negligible, but those manufacturers who have suffered from what may be termed the magnesia scare will be slow to underrate it.



Turning to actual specifications which have been used within the last ten or fifteen years, one is struck by several characteristics which they possess in common. The first is one that may be observed in most specifications of whatever kind—namely, an air of rigour and precision frequently covering looseness and inaccuracy. The second is the statement of the same requirement in different specifications in altered terms, apparently, consciously or unconsciously, adopted to lead to the belief that the specification has been evolved by the drawer from the profundity of his knowledge instead of being bodily annexed from some well-known source. The third is in the insertion of the particular fads of the deviser of the specification, wherein his true originality is amply displayed.

Coming to particulars, and taking a specification for important harbour work dated 1875, we find the first clause relating to the quality of the cement stipulating that it shall "weigh at least 116lb. per striked bushel." Nothing is said as to the mode of filling the measure, and the margin thus left to the skilful manipulator was naturally considerable. Instead of improving this ridiculous weight per bushel clause out of existence, later specifications, as will be seen, have simply endeavoured to give precision to a requirement intrinsically absurd. The same specification requires briquettes of neat cement 2¼ square inch in section to bear a tensile load of 350lb. at two days, 500lb. at four days, and 750lb. at seven days after gauging, the weight to be applied "slowly," and to hang upon them for "not less than one minute" without rupture taking place. These points are not of contemporary interest, but may be profitably compared with the requirements of more modern specifications. The fineness of the cement was to be such that not more than 10 per cent. should remain on a sieve, "the meshes of which shall be $\frac{1}{40}$ of an inch in the open"—whatever that may mean. In spite of this extraordinary wording it is easy to see, and reasonable to applaud, the idea latent in the mind of the drawer of the specification. He was aware of the fact that the fineness of a sieve depends on the area of each actual hole, and consequently that such a phrase as "40 meshes to the inch" is, as it stands, of doubtful meaning. In this respect many more modern specifications might be amended to embody the same idea with advantage.

One other matter may be noticed. It is stated in the specification that an inspector will be appointed to examine and test the cement, and much is left to his discretion. For example, the conditions already adverted to in no way touch the question of the *soundness* of the cement supplied. When it is considered that the very existence of a valuable structure may be terminated by the failure of the cement used in its erection, the imperative need of soundness will be obvious. Soundness in a cement holds the same place as honesty in a man—for those who have dealings with either. A cement may be strong, finely ground, and, to superficial tests, apparently unexceptionable, but if it be not sound it is a great deal worse than useless. At the time when the specification of which we are speaking was drafted, adequate tests of soundness were unknown or little regarded. A lurking sense of the paramount importance of securing it is to be detected by those who can read between the lines. For instance, it is laid down that the inspector will, when necessary, "test the cement with pats and dry briquettes in any manner which he may deem necessary;" further, there is a paragraph to the effect that "no cement will be accepted which, in the opinion of the inspector, is too quick setting, or likely afterwards to "fly" in the work, neither will any cement be allowed to be shipped on account of this contract unless it complies in all respects with the above conditions, and has been approved by the inspector." In this and in other respects, such as the manner of gauging, the amount of water used in that process, and so forth, the inspector is a kind of mechanical Cadi under a palm tree, and is almost unfettered in his judgment. The perusal of later specifications reveals much the same state of things. Now, provided an inspector of knowledge and probity can be secured, nothing better need be desired. His decision will be as much more likely to be equitable, as is the justice of our Cadi likely to be better than that of a more regularly constituted tribunal guided solely by rule and precedent. But the possession of these qualities is by no means a matter of certainty, and it may be readily conceived that a manufacturer undertaking a contract would prefer to be tied by hard and fast conditions, even if they be a little stringent, rather than by decisions the nature of which largely depends upon a personal equation. It is a belief in the existence and reasonableness of this preference that will lead us to consider, in our next article, other specifications, with a view of comparing them with that already dealt with, and of tracing, if possible, any process of evolution that may have taken place in the direction of the elimination of the personal factor and the substitution of accurate physical criteria.

SMALL SCREW CUTTING LATHE.

CONSTRUCTED BY MESSRS. LISTER & CO., ENGINEERS, KEIGHLEY.

GENERAL VIEW.

THE RUSSIAN IRON AND STEEL INDUSTRY.

FROM an official report recently issued on the Russian iron and steel industry, during the ten years of 1879-88, we gather the following particulars:—In 1888 there were in operation in the entire Russian empire 612 iron mines, and iron ore was further raised from 149 lakes. Of the former no less than 522 were situated in the government of Ural, and of the latter, 132 in Finland. The total output of ore, according to the *Iron Age*, amounted to 1,381,000 tons, of which 42,000 tons were lake ore. Compared with 1887, there is an increase of 75,500 tons. Naturally, the Ural shows the highest output — 778,000 tons. The number of works producing pig iron was 132, with 200 furnaces, producing 612,000 tons, of which quantity more than three-fourths was smelted with charcoal. Again the Ural shows the largest output—nearly 400,000 tons. The largest make at one works was 50,000 tons—viz., by the foundries La Nouvelle Russie, in the government of Catherinoslav, where, by the way, coke is solely used in the smelting. Compared with 1887, the make of pig has increased 52,000 tons, or nearly 9 per cent. During the period 1879–88 the manufacture of pig iron in Russia has increased 230,000 tons, or 54 per cent. Up to 1886 the

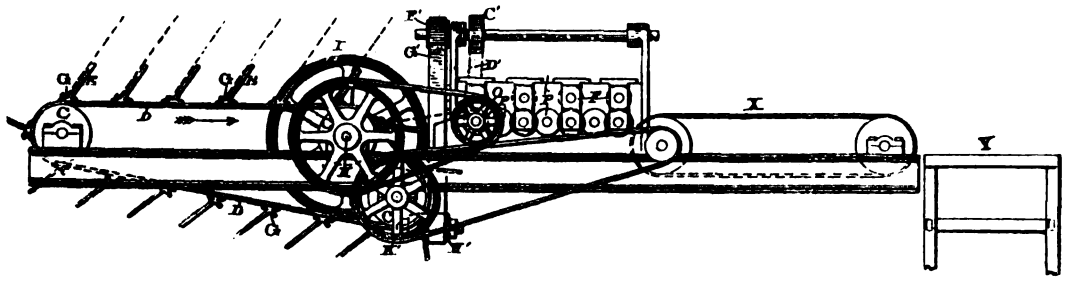

Fig. 1.—Side Elevation.

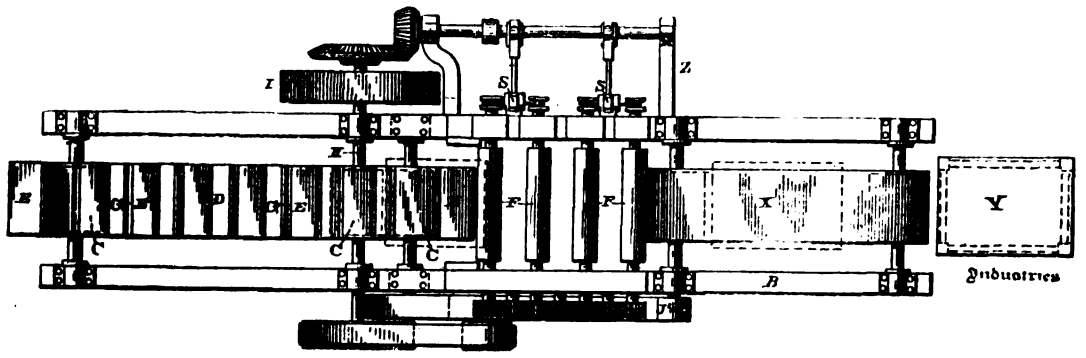

Fig. 2.—Plan.

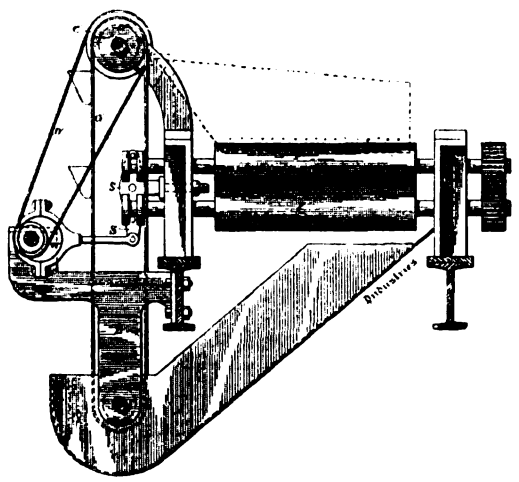

Fig. 3.—End View of Rollers.

increase was slow, amounting only to some 90,000 tons, but since then there has been a rapid progress. The greatest increase—41 per cent.—falls upon the district of Moscow. As regards the bar-iron industry, we learn that in 1888, 173 works were engaged in it, the make amounting to 350,000 tons, an increase since 1887 of only some 4,000 tons. The Russian bar-iron industry shows but slow progress during the period 1870–80, the total increase being only 81,000 tons. Like the bar-iron industry, the Russian steel industry advanced insignificantly in 1888, the manufacture amounting to 211,000 tons, or only 3,000 tons more than in 1887. The production has decreased as much as 37 per cent. in Finland, on account of the standing still of the largest steel works in that country, but increased in other provinces. At the works of the well-known Muta-Bankowa Company, the increase of manufacture amounted to 3,500 tons. During the decennial period referred to the manufacture of steel in Russia has fluctuated very much; for instance, 1880 shows a production amounting to 300,000 tons, whereas, in 1885 it had declined to 180,000 tons. Of the quantity produced in 1888, 1,100 tons were made by casting, 2,300 tons by puddling, 49,500 tons by the Bessemer and 154,000 tons by the Martin process, and 4,100 tons by the Franche Comté process. The number of steel works in the country was 32. The manufacture of steel rails amounted to 61,000 tons. Finally, as regards the relations between the consumption and the iron required to be imported in Russia to cover the former, we learn that the country supplied in 1888, 90 per cent. of the pig iron required, 85 per cent. of the bar iron, and nearly 96 per cent. of the steel. The report also contains a table which shows in the most striking manner the effect exercised of late years by the steady increase of duties in Russia—viz., a falling off of imports and increase of production, particularly as regards pig iron. Thus in 1879 the production of pig amounted to 420,000 tons, and the imports to 180,000 tons; whereas, after ten years of steadily increasing protection, the relative figures were 612,000 tons and 73,000 tons.

MACHINE FOR CLEANING TINPLATES.

The Americans appear to be conscious of the fact that, notwithstanding the McKinley Tariff, it will be impossible for them to compete successfully with South Wales in the manufacture of tinplates unless mechanical appliances are largely adopted in the place of our hand labour. It will be a matter of considerable interest, therefore, to watch the various applications of machinery to operations which, owing to our cheaper labour, have generally been done by hand in this country. Chief amongst these is the rubbing and dusting of the plates after they have received the tin coating—an operation that prepares them for the assorters. This work, which is eminently fitted for women and girls, is accomplished at a cost that hardly reaches 1½d. per box. It would, therefore, appear that there is no great margin for a reduction in the cost of manufacture on this head; nevertheless, if—as may be quite possible—a machine can do the work for the odd ½d., saving the 1d. per box to the manufacturer, we have the possibility of a total saving of £25,000 on six million boxes—a quantity that is below the total make of the last six months.

We are, therefore, pleased to place before our readers several illustrations, representing, in Figs. 1, 2, and 3 a side elevation, a plan, and end view respectively, of a machine for cleaning tinplates, the invention of Mr. Isaac Davies, of Phœnixville, Pa., U.S.A., controlled by Messrs. Davies & Phillips, 200, Walnut Place, Philadelphia, and constructed by the Trethewey Manufacturing Company, of Pittsburgh. It will be seen that the main parts of the apparatus are an endless band D with supports E for the tinplates to lean against as they are carried forward by the motion of the pulleys C. As the belt continues moving in the direction of the arrow in Fig. 1, each plate is carried round and automatically delivered between the first pair of a series of rollers F (Fig. 3), which, in addition to the rotary motion, have a reciprocating motion imparted to them by the levers S worked from the eccentric W. Thus, as the top rollers are moving endwise in one direction, the bottom rollers move in the opposite one, and by this means a thorough rubbing or scouring of the plates passing between them is effected. The plates are then deposited upon the endless belt X, which conveys them to the table Y in the assorting room. The bran, sawdust, or other cleaning material falls into the chute I^1, from which it is readily gathered by buckets attached to the belt G^1 (Fig. 1), and carried up to continue the operation.

The particulars and illustrations are taken from the *American Manufacturer*, but our contemporary does not mention the material of which the rollers are made. It is obvious, however, that they must be covered with leather or some similar material. Nor is it very clear whether the plates are cleaned at one pass, for the bran does not appear to have access to the under side of the plates, and a second passage through the machine with the plates reversed would, in that case, seem necessary in order to complete the operation.

ON TESTS FOR STEEL USED IN THE MANUFACTURE OF ARTILLERY.*

(*Concluded from page* 531.)

There is no contesting the fact that the effects above described do follow sudden changes of temperature; but the action is by no means regular, because both the allotropic and chemical changes in the material are influenced not only by changes of temperature, but also by the state of pressure or tension which such changes tend to produce, so that certain combinations of pressure and temperature may develop much more marked effects than others. This is well illustrated by the changes which take place in drawing and rolling metals and their alloys; they are rendered hard and brittle by mechanical tensions and pressures alone, and often to the same degree as by sudden cooling. The difficulties which surround the framing of a specification for gun-steel were enhanced by the circumstance that till quite lately the steel makers did not manufacture guns, at least for Her Majesty's service, while the gun makers did not produce the steel which they required. Hence it became necessary to test the material practically in the rough forged state, and by a process which aimed more at ascertaining what the steel was likely to do when ultimately treated in the recognised manner, than to determine its properties in the particular state in which it was tested, which was consequently not the condition in which it was to be built into the gun. The specification now in force in Her Majesty's service lays down that the specimens, which are to be cut from the components of the guns in a carefully specified manner, are to be 1in. *diameter* by 4½in. long; they are to be heated to 1,425° Fahr., or a bright red, and quenched in oil of 65° Fahr. temperature, and left in the oil till cold. They are then to be turned down for a length of 2in. to a diameter of 0·533in., and tested by tearing asunder. Bending tests on specimens 4½in. long, and 0·75in. wide, and 0·375in. thick, cut to these dimensions after being oil hardened, are also prescribed. In samples so small the probability is that the internal stresses set up by the oil treatment, even though it is not followed by annealing, are not very severe, and they are greatly relieved, in the specimens tested by tension, by turning off nearly a ½in. all round the operative part. But the temperature at which the hardening is effected lies between two temperatures at which important molecular changes take place in the material. The researches of Gore, Barrett, Osmond, Professor Roberts-Austen, and others, show that at about bright red heat, or 1,500° Fahr., iron undergoes a molecular change, made manifest by the evolution of heat sufficient, if not actually to raise the temperature of the metal, at any rate to retard its rate of cooling. Such evolution of heat must be due to molecular or atomic change, which is clearly reversible. In heating a bar, the rate of absorption must be momentarily increased at the point of recalescence; in other words, the specific heat of the material is increased at a particular temperature; or rather, as a molecular change has taken place, the heat absorbed or evolved should be more correctly called latent. We have no information as to whether a change in specific gravity takes place also; but since liquid iron is more dense than solid, it seems probable that increase of density commences at the point of recalescence, and is maintained when the metal passes into the fluid state. A similar phenomenon is apparent in water, which attains its maximum density at 39° Fahr., and then commences to expand as the temperature falls, and maintains that expansion till converted into the ice into which it ultimately turns. Water colder than 39° Fahr. appears to be an allotropic form of water warmer than that temperature.

The allotropic change which takes place in iron at 1,500° Fahr. is probably accompanied by a change in physical properties, producing what Osmond has called α and β irons. Apparently, when the change takes place in gradual cooling, the β iron, that of the higher temperature, and which Osmond conceives to have hard molecules, passes into the α state, in which he supposes the molecules to be soft. Cooled rapidly, in either state soft iron results; but in the presence of carbon or of some other substances, the β iron is supposed to retain some of its hard nature, and to be the cause of hardening in steel.

In addition to this change in the iron, which forms the main component of steel, it is now demonstrated by the researches of the President, Akerman, Osmond, and others, that the carbon, at any rate of steel, exists in two conditions, namely, either in the form of a definite compound of carbon and iron dissolved in an excess of iron, or as finely subdivided carbon diffused through the mass, and that at certain temperatures association and dissociation take place, the combined carbon becomes diffused, and the diffused carbon combines. The act of combination being a chemical process, might be expected to declare itself in the evolution of heat, and the researches of Osmond, laid before this

* Paper read before the Iron and Steel Institute on the 6th ult., by Dr. W. Anderson, M.Inst.C.E.

Digitized by Google

Institute last year, abundantly show that at about the temperature of 1,200° Fahr., or red heat, such an evolution of heat does take place.

Struck by the importance of the researches to which I have drawn your attention, and imagining that the methods pursued by Osmond opened up the possibility of arriving at a knowledge of the condition of large masses of steel with respect to their uniformity of composition and physical condition, I suggested to the Institution of Mechanical Engineers that it could not do better than institute a systematic research into this matter. The proposal was adopted with the utmost readiness; a strong committee, of which our President is a distinguished member, was formed, and Professor Roberts-Austen was requested, adequate assistance being provided, to undertake the work. He readily accepted the task, and I venture to think that already very encouraging success has been met with. It would obviously be improper for me to explain here the means by which the work is being carried out. A report will very shortly be presented to the Institution of Mechanical Engineers. It will contain the fullest information, and I will therefore only state that Osmond's experiments have been repeated, the rate of cooling of specimens has been registered by the most ingenious automatic methods, and curves produced from which it is possible for even an inexperienced eye to detect the two points to which I have drawn your attention. The mode of procedure requires but very small samples, and a few minutes suffice to obtain a record; so that I am sanguine that before very long a method will be arrived at by which it will be possible to determine the quality and conditions of masses of steel, from the mere shavings turned off, far more accurately and rapidly than by means of any test which we are able at present to apply; and this power is of vital importance now that we propose to build up guns of immense masses of steel, the quality of which, though it may be determinable by present methods at the ends, cannot be ascertained without great loss in other parts of their length.

The investigations prove, at any rate, that steel is being treated, or ill-treated, now at temperatures which lie between two critical points, separated from each other by only some 300° Fahr. It has to be treated in masses of ever-increasing magnitude, and the temperatures at which the hardening and annealing are performed can only be judged of by the eye—an extremely unsatisfactory method, considering how much the appearance of a heat is modified by the intensity of the light around. I cannot divest myself of the feeling that the apparently capricious behaviour of steel is due not only to the internal stresses engendered by oil hardening, but also to the circumstance that the chemical condition of the steel, and its molecular structure, are greatly influenced by comparatively slight errors of judgment, or by carelessness in the adjustment of the temperatures at which the operations are performed. The circumstance that within the last two or three years three important firms have undertaken the manufacture of heavy guns from steel of their own producing, and have introduced powerful forging presses, renders it possible to modify our specifications in the sense that more attention shall be paid to the nature of the steel employed, and to the mode of working it, than heretofore. It is in contemplation to provide that open-hearth steel only shall be used; that the ingots shall be treated in a special manner when hollow forgings are to be produced; that a certain minimum amount of work shall be put into the steel, and that annealing from a red heat, or about 900° Fahr., shall always be the last operation, even if the mechanical properties aimed at can be attained without hardening in oil or water.

It is remarkable that foreign nations appear to attach much more importance to determining the elastic limits than is done in Her Majesty's service. The French and American specifications prescribe both the elastic limit and the ultimate strength. The Russian specification defines the elastic limit only, though the ultimate elongation per cent. is prescribed. I believe that the Germans follow the same rules, though I have been unable to obtain any direct information on this point. In Her Majesty's service a limit of permanent extension under a load of 21 tons per square inch is prescribed, and a note is to be taken of any yielding under a less load; but the term "elastic limit" is carefully excluded, on the ground that no such limit can, in fact, be defined.

All foreign nations seem to prescribe hardening in oil, though no mention is made of any particular temperatures, and in all cases the first and the last operation must be annealing, after which only the test-pieces are taken. At the Abouchoff Steel Works the hardening and annealing is practically one operation, the object to be treated being immersed in the oil only for a short period, the duration of which is a matter of judgment, and depends upon the dimensions of the steel. It is then rapidly withdrawn, and returned to the heating furnace, where it is allowed to cool slowly.

It is impossible, within the limits of a paper suited to these meetings, to enter into all the details of the question I have ventured to bring before you. My object is to draw attention to the recent advances in the theory of steel, and to suggest how the knowledge, even now, in our posession must gradually affect our practical work. I trust that the discussion, which will no doubt arise, will give to the world the knowledge and experience which is so peculiarly the dower of the members of the Iron and Steel Institute.

ECONOMICAL PUDDLING AND PUDDLING CINDER.*

In 1784, or a hundred and seven years ago, Cort invented the puddling process, and thus laid the foundation of much of the prosperity of this country during the century which followed. The present importance and vitality of the industry is shown by the remarkable fact that, despite the wonderfully simple method invented by Bessemer, and the beautifully perfect furnace of Siemens, it has required thirty-five years of sharp competition to render the weight of Bessemer ingots annually produced in this country equal to that of the puddled bar manufactured by the old process. This vitality is due in great measure to the fact that, for certain purposes, the characteristic properties of wrought iron render it preferable to mild steel, and is doubtless also in part due to the circumstance that in many cases capital has been invested in an ironworks, and cannot now be easily realised or converted into more modern plant. At all events, the success of the puddling process can scarcely be due to the interest which ironmasters have in the past taken in the more theoretical or scientific aspect of their business, for we find, on examining the literature of the subject in this country, that, with the notable exception of Mr. Henry Kirk, of Workington, one of the original members of the Institute, the contributors have been, almost without exception, either professional chemists or teachers, and may, therefore, like the writer of this paper, be considered amateurs. For our knowledge of the manufacture of cast iron and steel, on the other hand, we depend largely on the work of men connected with the particular branch they studied, and it is somewhat characteristic that the best known, and probably the first systematic, investigation of the changes which take place during puddling was made a year after the Bessemer process was introduced. Even at the present day, despite the fact that this Institute has been in existence over twenty years, there are to be found those who successfully conduct ironworks, and yet have no more understanding of the theory of the process than had Cort himself a century ago.

This apparent want of interest shown by the practical man in the scientific aspects of puddling is probably due in part to the knowledge that the information generally supplied is either incomplete, and not quite what is wanted, or that it is actually incorrect, and consequently misleading. As an example of the first, we are commonly informed that the impurities of the pig iron are oxidised by the oxide of iron present in the fettling, and such an explanation, when it is added that the carbon passes off as gas, while the silicon, phosphorus, and manganese remain as oxides in the slag, is generally considered sufficient. To this it may reasonably be objected that it is very doubtful whether it is possible successfully to puddle a tolerably pure pig with pure ferric oxide alone. It would, at all events, certainly lead to waste of time and metal in the early stages of the process, owing to a deficiency of fusible cinder, would probably lead to thick slag and inferior iron at the end of the process, and would also be very liable to cause the bottom to scurf. These facts show the importance of a due proportion of silica, ferrous oxide, and phosphoric anhydride in puddling cinder in order to ensure the requisite fluidity, a point which is seldom referred to in explanations of the process. But further information is also necessary as to the manner in which the oxide of iron present in the furnace acts upon the impurities of the iron. Thus, if we consider, for simplicity only, the case of carbon, a number of actions are possible, such as—

$$\left.\begin{array}{l}(1.)\ Fe_2O_3 + 3C = Fe_2 + 3CO\\ (2.)\ Fe_2O_3 + C = 2FeO + CO\end{array}\right\}\ \text{With ferric oxide.}$$

$$\left.\begin{array}{l}(3.)\ Fe_3O_4 + 4C = Fe_3 + 4CO\\ (4.)\ Fe_3O_4 + C = 3FeO + CO\end{array}\right\}\ \text{With magnetic oxide.}$$

$$(5.)\ FeO + C = Fe + CO\quad \text{With ferrous oxide.}$$

If 12 parts by weight of carbon be taken as a standard for comparison, and the above equations are arranged in the order of iron reduced and fettling used, we have the following values:—

Equation.		Iron Reduced.		Fettling Used.
(5.)	...	56	...	72
(3.)	...	42	...	58
(1.)	...	37	...	53
(2.)	...	0	...	160
(4.)	...	0	...	232

Hence, taking the two extremes, according to equation (5). 1lb. of carbon would reduce 4⅔lb. of iron, and use 6lb. of fettling; while, according to equation (4), 1lb. of carbon would reduce no iron, but use 19⅓lb. of fettling; yet a well-known Cleveland chemist uses equation (5) to explain the removal of carbon, while the author of a recently issued text-book explains the action according to (4).

Now the most important reaction for the removal of carbon may be some one of the five above represented, or the process may be the result of several, or of all of them together. Again, the reaction by which carbon is removed may be of one kind, and that by which phosphorus is eliminated may be of another, and thus a whole range of possibilities is opened up to view, on which, so far as I am aware, no definite information is at present attainable. And yet these questions are of the greatest practical importance, as their solution would enable us to theoretically predict the yield of an iron of known composition, and to say what quantity and composition of fettling would give the most satisfactory results. At present we only know that some of the "commonest," that is, the most impure irons, give the largest yield in the puddling furnace; but these irons lose most in the mill, the final result being approximately an equal weight of finished iron in each case. The quantity and quality of fettling also is usually arrived at by trial, frequently involving much loss from waste and trouble; and having once been determined, is often regarded as an important trade secret, and is rigidly adhered to, despite the variations which are usual in the pig iron to be treated. These remarks will perhaps be sufficient to indicate the incompleteness of our present knowledge, but it may be well just to point out that the information derived from other processes, or from crucible experiments, will in many cases prove but an unsafe guide to the understanding of the changes which take place in the puddling furnace.

To illustrate my statement that the explanations given of the puddling process are frequently incorrect, and consequently misleading, we have merely to examine the usual chemical and metallurgical text-books. The late Dr. Percy, in his classical "Iron and Steel," was inclined to favour the view that during puddling phosphide of iron was separated by liquation, and he regarded the exact explanation of the removal of phosphorus as obscure. Greenwood, twenty years later ("Steel and Iron," 1884, page 253), favours a similar view, stating that "the rationale of its separation is not clearly understood." On the other hand, Miller ("Chemistry," sixth edition, 1878, edited by Groves, page 624) states that silicon and carbon are removed during the earlier stages of the process, while sulphur and phosphorus resist oxidation, but are afterwards removed by the violent stirring of the puddler when the mass is becoming granular. Bauerman, again ("Metallurgy of Iron," 1882, page 329), who gives a more than usually good account of puddling, says, "The removal of the foreign matters takes place in the following order—first silicon, then manganese, then phosphorus, and, lastly, sulphur." One further illustration will suffice. Hiorns ("Iron and Steel Manufacture," 1889, page 88) gives merely the following naïve explanation:—"The ferruginous slag formed takes up oxygen from the air, causing FeO to pass into Fe_3O_4, which then oxidises the impurities in the order of their oxidisability—viz., silicon, manganese, phosphorus, sulphur, and carbon." It will be sufficient to remark, with regard to this extract, that the order given is not the "order of oxidisability" of these elements, and that when the elements are combined with iron the "order of oxidisability" depends altogether upon circumstances.

These quotations show that even in connection with such an important matter as the removal of phosphorus, one of the most fundamental reactions of puddling, considerable difference of opinion is expressed. Thus one author asserts that phosphorus is removed at the beginning of the process, another that it is eliminated at the middle, a third that it passes out at the end, and a fourth that it is eliminated uniformly throughout the whole operation. To make the matter complete, we only need some one to assert that it never passes out at all! In view of such confusion, and bearing in mind that one reason for the continued prosperity of the puddling process is the fact that it is most suitable for a class of irons too rich in phosphorus for use in the acid processes of steel-making and too poor for the basic processes, it is no wonder that practical men have felt inclined to pay but little heed to the theoretical aspects of their business. The conditions which influence the success of the work in the forge may be divided into two classes, according to whether they are directly or but very indirectly connected with chemical considerations. Of those conditions which are outside the province of the chemist, there is, of course, the fundamental question of finance, which is the backbone of all industry, but which cannot be discussed here. In addition, we have the necessary working conditions, which include:—

1. A furnace of suitable shape, size, and construction.
2. Fuel, which must be cheap, fairly pure, and of high calorific power.
3. Cheap and skilful labour.

In connection with suggested improvements in the first of these conditions, great hopes have been raised and enormous sums of money expended since this Institute was formed. And yet, in this country at all events, rotating or revolving furnaces after extended trial have been abandoned, double furnaces are seldom used, and any mechanical aid to the puddler is quite exceptional. Gas-firing, too, is but seldom employed, since with small puddling furnaces this leads to complications of ports and valves, to reduce which larger furnaces are necessary. Hence, to obtain the full benefit of gaseous fuel, larger blooms and fresh machinery would be necessary, and it is found more convenient to melt and cast the metal, since a sufficiently high temperature is at command, and thus steel is obtained.

At present, therefore, there seems to be no halting-place between the use of the ordinary puddling furnace on the one hand, and the manufacture of steel on the other. In the palmy days of the iron trade, the family of Crofts of Tipton were I believe, the chief furnace-builders of this country; and the furnaces used in Staffordshire, which is the chief wrought-iron making district of the world, and hence may be considered representative, are still almost exactly of the pattern then built. In some cases improvements have been introduced in the methods of cooling the bridge and sides; closed fire-places with forced draught, or fire-bars of special shape are successfully used with small fuel, while the water-cooled doors used by Mr. Yeomans at the Old Hill Works, belonging to N. Hingely & Sons, Limited, are a great advantage to the puddler. Otherwise, so far as I am aware, there has been little alteration during recent years.

In dismissing the third condition of success above enumerated, I dare not attempt to discuss the great questions of to-day, upon which members of this Institute are divided; but I feel confident of this much, that the continuance of the Staffordshire iron trade has been rendered possible only by the fact that during the last fifteen years puddlers of unusual skill have been obtained at moderate wages, and that if this condition of things were seriously altered, it would be most disastrous to the trade of a district already heavily handicapped by its distance from the seaboard.

Among the conditions which come more directly within the province of the metallurgist and chemist, we have the composition, amount, and physical and other properties of—

1. The metal employed.
2. The fettling used.
3. The wrought iron obtained.
4. The cinder produced.

These conditions are naturally closely related to each other, and are to a large extent interdependent. Their proper understanding also necessitates an acquaintance with the nature and sequence of the changes which take place during the puddling process.

To discuss the question of the relative economy of forge irons of different chemical composition would involve more time and space than is at my disposal, and this is less necessary on account of the fact that during the last few years several papers have been published on this particular subject—the more important of which are those by Mr. A. E. Tucker and Mr. H. Kirk—which would well repay the careful perusal of those interested in the matter. In Mr. Tucker's second paper are to be found analyses of upwards of fifty samples of pig iron, most of them forge irons, and in the majority of cases the price of the iron is given with the analysis. Having had several opportunities of examining the large number of analysed samples of forge irons thus collected, I can testify to the interest and value of such a collection. Mr. Tucker emphasises the untrustworthiness of fracture as an indication of composition, and the extraordinary want of relation between some of the market prices of pigs and their real value, both of which are points of great importance. Mr. Tucker further shows how the approximate value of a pig for forge purposes may be estimated, the basis of his calculations being the statement that the process of puddling "consists in the absorption of silicon, sulphur, phosphorus, and manganese, contained in the pig iron, by the oxide of iron used in the fettling and in the removal of the carbon by the reduction of the fettling to metallic iron. We have, therefore, a debit and credit account, a loss in weight due to the bodies named, and a gain in weight due to the production of metallic iron from the fettling." Such a

THE NICARAGUA CANAL.

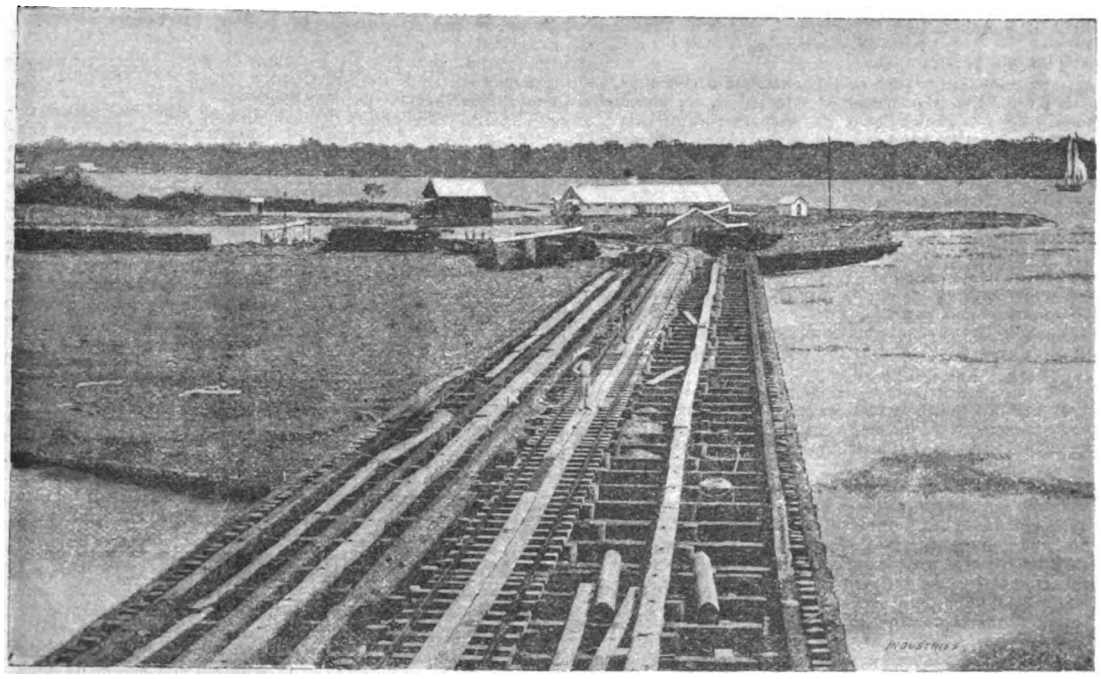

Fig. 13.—The Breakwater at Greytown looking Landward.

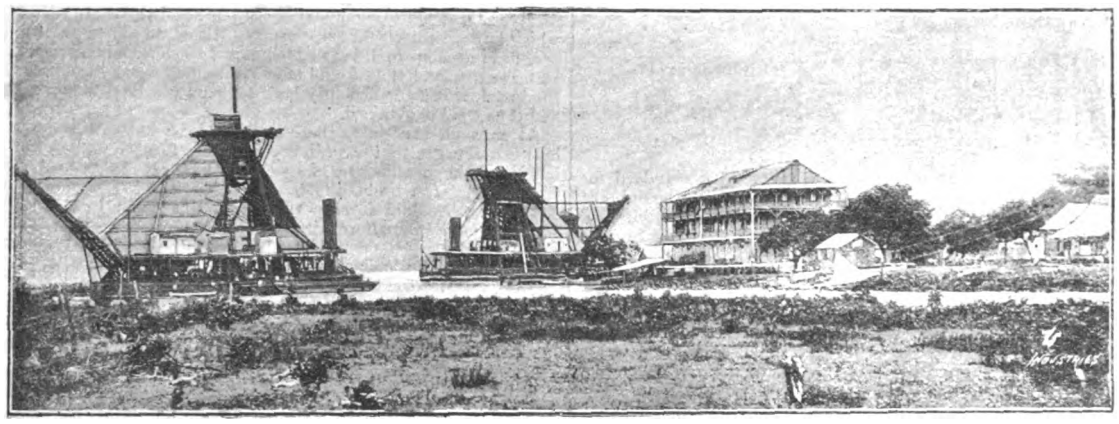

Fig. 14.—Storehouse and Dredgers "Dingler" and "City of New York" at La Fé.

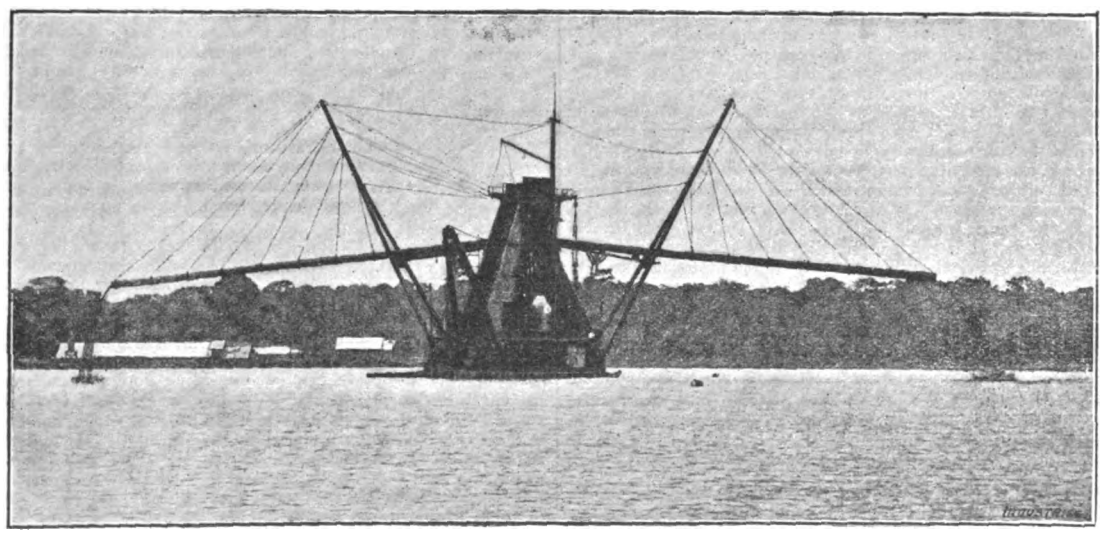

Fig. 15.—Dredger "City of Paris" at Work in Greytown Harbour.

method of calculation is simple, and certainly enables one to distinguish between a good pig and a very bad one; but, after all, it is merely an approximation to the truth. For it is probable that some at least of the carbon is oxidised by ferric oxide without reducing an equivalent quantity of iron from the fettling; and it is pretty certain, on the other hand, that silicon, sulphur, phosphorus, or manganese may, under suitable conditions, be oxidised by ferrous oxide, and thus reduce some iron from the fettling. Hence the rule above given, though useful in many cases, fails to explain why an iron unusually rich in phosphorus and silicon often gives the largest yield of puddled bar, while a very pure iron will also yield a greater weight of puddled bar than that of the pig iron charged into the furnace, and an intermediate iron, of what may be considered good ordinary quality, loses 3¼, 5, or more per cent. of its weight. It is in order to explain these apparent anomalies that, as I have previously pointed out, more accurate knowledge is required with reference to the action of oxide of iron on the various impurities in puddling.

Before leaving this part of the subject it may be well to give the approximate composition of forge pig iron of typical kinds, as used in South Staffordshire:—

	No. 1.		No. 2.		No. 3.		No. 4.
Carbon.....	2·60	...	3·60	...	3·00	...	not given
Silicon.....	1·20	...	1·25	...	2·00	...	·992
Sulphur	·08	...	not given	...	·10	...	·144
Manganese...	·50	...	·50	...	·25	...	·693
Phosphorus..	·57	...	1·00	...	1·80	...	1·233

No. 1 is an analysis of South Staffordshire all-mine pig, a turn of six full heats of which would require about 26½ cwt. of pig and 13 cwt. of fettling, while it would yield about 27½ cwt. of puddled bar. No. 2 is the composition of a standard pig for puddling, as used by Mr. Tucker for purposes of comparison; this will work into puddled bar with a loss of about 3½ per cent. No. 3 represents a cheaper part-cinder mixture used in South Staffordshire, and which is not very different from Cleveland pig. No. 4 shows the average consumption of a half-year's pig iron of all sorts, best, crown, and common together, as given by Mr. Kirk in his paper above mentioned, and the yield, as verified from the firm's books after stockstacking, showed a loss of exactly 3¼ per cent. With an iron of this composition, Mr. Kirk has shown that seven heats per turn may be regularly obtained. I need scarcely add that such results are not merely unusual, but unexcelled.

The presence of some silicon is necessary in forge iron for the ordinary or "boiling" process, as otherwise the iron is "dry" and unsatisfactory in the furnace, though this can be to some extent remedied by the use of hammer slag or other silicious fettling. Generally, the cheaper forge iron in Staffordshire are too silicious and "hungry." This requires more time, uses more fettling, makes the cinder too thin, and gives a brittle bar. Some phosphorus is also an advantage in puddling, as it prevents the cinder from getting too thick at the end of the operation, and thus causing a variety of red-shortness. Too much phosphorus, on the other hand, leads to waste of iron and fettling, and renders it impossible to produce a good fibrous iron, unless, indeed, an unusually large proportion of fluid cinder is used, and the boil is conducted at the very highest attainable temperature. The presence of manganese is an advantage, as it indirectly assists in the more complete elimination of phosphorus. It is not possible to lay down any hard and fast lines as to a best or typical composition of pig for forge purposes. This will vary largely according to the local conditions, the fettling employed, and the quality of the product. In this country the pig iron made from the clay ironstone of South Staffordshire, South Wales, and West Yorkshire, is of the highest reputation, and, chemically, is all that can be desired; while, when it can be obtained, such an iron as that used by Mr. Kirk can be thoroughly recommended.

(To be continued.)

THE NICARAGUA CANAL.

VI.

WORK SO FAR ACCOMPLISHED.

(Concluded from page 533.)

On the 25th of May, 1889, the first expedition for the construction of the canal left New York, and landed near Greytown at the proposed entrance to the channel on the 3rd June.

The indispensable preliminary to the formation of the canal itself was, of course, the improvement of the harbour of Greytown. The first operations were necessarily of a pioneer character, and attended with considerable difficulties. Temporary shelters for the protection of men and stores had to be erected, and means of transport along the route of the canal through swamps and virgin forests to be provided. It was also necessary to establish telegraphic communication with the nearest station, over 100 miles distant from the coast, and between the various camps and the base of operations. Owing to the absence of a harbour, from causes already explained, ships have hitherto been obliged to anchor about two miles off shore, and all machinery and supplies had to be landed in lighters through a shifting entrance and over a dangerous bar.

The formation of a channel from the sea into the bay was, under such conditions, the first work required, and this was put in hand as soon as practicable. A breakwater is in process of construction, and, under cover of this, the dredging of the entrance channel is being carried on.

According to the most recent report of a party of engineers and scientific men, who returned to New York from a tour of inspection of the canal works on the 6th ult., the breakwater at Greytown, a view of which we give in Fig. 13, now extends 1,000ft. into the sea, and there is a depth of 14ft. of water where previously the bar existed blocking the entrance to the harbour. In the early part of the present year the first steamer passed over the site of this bar. Six large dredgers are on the spot, of which two are at work, while three more will shortly be ready. Three of these—the "Dingler," "City of New York," and "City of Paris"—are shown in Figs. 14 and 15. The excavation of the channel to a depth of 17ft., with a width of 270ft., has been accomplished for a distance of half a mile, the proposed depth being 30ft. For a distance of over ten miles the dense vegetation covering the country has been cleared from the line of the canal. Two views of the clearing work are shown in Figs. 18 and 19 on page 564. Many miles of broad gauge railway are already built, part of which is to connect Greytown with the site of the Eastern Divide Cut. Of this latter portion ten miles has now

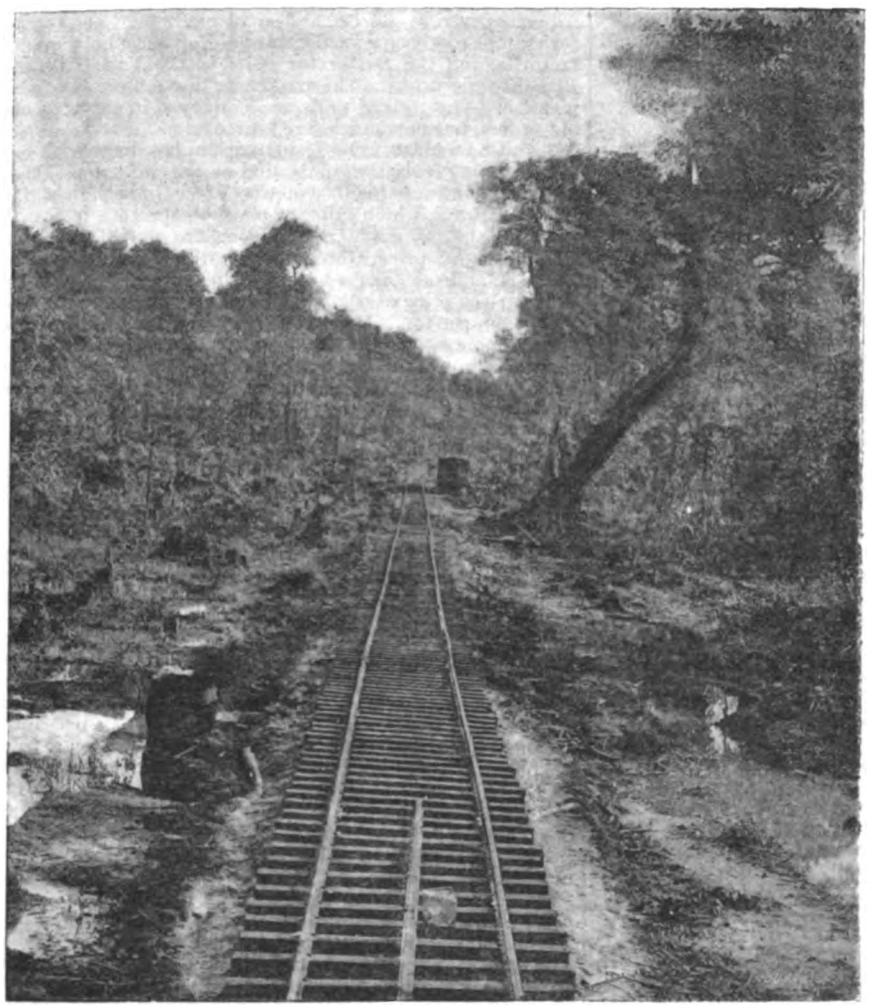

FIG. 16.—COMPLETED RAILWAY THROUGH SWAMP OF GREYTOWN.

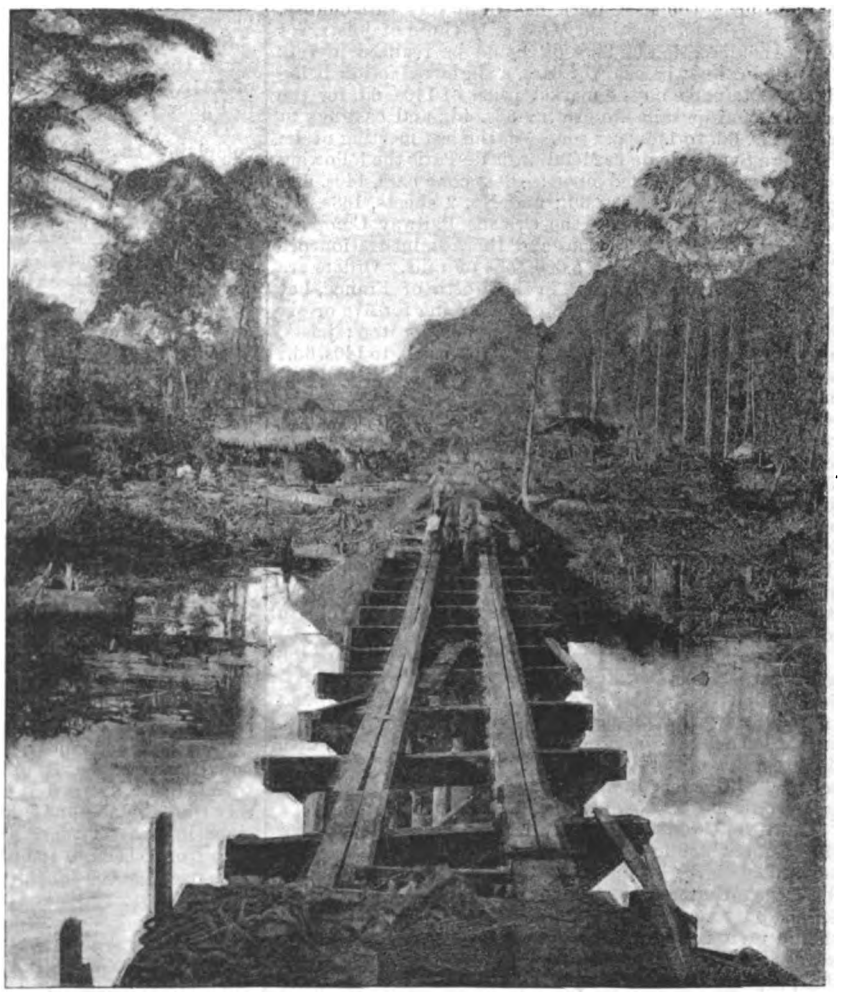

FIG. 17.—RAILWAY BRIDGE ACROSS BENARD CREEK.

been constructed, parallel with the line of the canal, for the transportation of men and machinery, so that the work may be pushed forward simultaneously at different points. We give above, in Fig. 16, a view of the completed railway through the swamp of Greytown, and Fig. 17 shows the railway bridge which has been constructed across Benard Creek. Besides this, machine shops and storehouses, docks and wharves, together with fifty buildings, including hospitals, offices, and quarters, have been erected by the company, some of which we illustrated in our last issue. As the water in the vicinity of Greytown is unfit for human consumption, an aqueduct, thirteen miles in length, has been made, which brings a supply of pure water from the mountains.

Before concluding these articles, we may mention that the Committee of Foreign Affairs of the United States' Senate unanimously recommended a short time ago that a Bill should be brought forward providing for a Government guarantee of the principal and interest of $100,000,000 of bonds to be issued by the Nicaragua Canal Company. We learn, however, from the United States' Consul-General in London, that this Bill has not yet been passed, although its prospects of success at the beginning of the year were decidedly hopeful.

THE STEAMSHIP OF THE FUTURE.

A STEAMSHIP to cross the Atlantic in three days is coming within the sphere of practical engineering and naval architecture, if we are to place any reliance on the opinions of Mr. Carl Schurz, of New York, the President of the Hamburg-American Packet Company. That gentleman was recently tackled by an interviewer, and expressed himself as a great believer in fast time. In his opinion it was quite possible to build ships which could perform the run from New York to Liverpool in three days, and without any greater danger than in the case of the six or seven day steamers of the present day. Mr. Schurz, although sixty years of age, hopes to see his idea carried out during his lifetime if we go on improving at the rate we are going now. He points out that twenty-five or thirty years ago any one would have been ridiculed if he had predicted that ships could cross the Atlantic as they are doing now in a little over six days. He thinks, however, that three or four day ships would not carry freight and passengers, but only the latter, and as the passenger traffic to Europe is constantly increasing this could be done at such rates as to make it profitable. Nowadays, in the regular season, all the ships are crowded to their utmost capacity. People have more money to spend, and not only are more people travelling, but there are more who are taking the expensive lines.

Mr. Schurz has formed his ideas as to the designs of the steamships of the future. They will, he states, be considerably larger than the present vessels, and of course will require engines of greater power in proportion to their size. They must have two distinct sets of boilers, two sets of engines, two shafts, and two screws, both sets working independently of each other, and separated by one solid longitudinal bulkhead, running from the keel to the upper deck, and dividing the vessel into two non-communicating halves, each of which is fully equipped to propel the ship, so that an accident occurring to one side of the ship will in no way affect the other, whose machinery will continue to propel and work the ship with the greatest ease. The water-tight compartments will confine to one compartment any accident that might happen.

In connection with the foregoing we may state that some of the most prominent shipbuilders on the Clyde have been credited with the intention of building a steamer which will be able to cross the Atlantic in five days as soon as they got shipowners enterprising enough to give them the order. Several such orders are said to have been "in the air" for some time, but nothing definite yet appears to have been settled. Possibly the shipowners are waiting until the subject has been a little more discussed by engineers and shipbuilders before they undertake the risk, which involves such a large amount of capital. In the meantime, however, the builders of the "City of Paris" and the "City of New York" have so far taken the matter out of the sphere of speculation as to produce a model of a steamer which is designed to cross the Atlantic in five days. Messrs. James & George Thomson have a reputation which places everything they propose at once within the range of practical engineering, and we have little doubt that they are perfectly competent to perform all they promise. The model is exhibited at the Naval Exhibition, and, although it is impossible to ascertain details from it, still a general idea may be formed. From the engine coamings it would appear as if it were intended to have two sets of engines, placed tandem, driving each screw, giving four complete sets of engines. The "City of Paris," with two sets, each indicating 10,000 h.p., made a speed of 21 knots with nine boilers. If the engines and boilers were doubled in the new ship, it would be possible to have an aggregate power of 40,000 if it were needed, and this should be more than sufficient to give the speed necessary to cross the Atlantic in five days. We should, indeed, imagine that a mean between this and that developed in the "City of Paris"—that is, 30,000 h.p.—would be sufficient, but this can only be ascertained, even approximately, when we know the design of the hull, and after experiments are made with it, for at the higher speeds all calculations are largely matters of guess. Of course, on this point, considering the great competition among shipbuilders for the leading places, Messrs. Thomson do not feel inclined to give much positive information. The subject, however, is one of great scientific and practical interest, and we shall be pleased to have the opinions of some of our readers regarding it.

FATAL ACCIDENTS IN WELSH MINES.

FROM a report of the Government Inspector of Mines for South Wales recently issued, we learn that South Wales is in an unfavourable position as regards safety in working. The proportion of tons raised per life lost in South Wales is 90,410, against a proportion of 167,763 tons raised per life lost as an average throughout the kingdom. In Durham, where the mines appear to be the safest, the proportion is 388,149 tons raised per life lost. In South Wales one person is killed for every 338 employed, the average for the kingdom being one killed for every 528 employed, and for Durham one killed for every 1,080 employed.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 9th June, 1891.

IRON.—The amount of business done on the Paris iron market during the past week has been very satisfactory. Prices were well sustained, especially those of joists, for which the quotation of 148s. 6d. could be realised in full. The same cannot be said for bars, a slight reduction being always obtainable on the market price of 140s. 6d. for the latter. Old iron rails are firm at 88s. 4d., and castings at from 112s. 6d. to 114s. per ton. At the last meeting of La Chambre Syndicale de la Métallurgie de Paris the following quotations were decided upon:—Best coke bars, 140s. 6d.; joists (1st quality), 152s. 6d.; and No. 2 sheets, 168s. 8d. per ton. It is stated that the Orleans Railway Company are going to order 12,400 tons and the Administration des Chemins de fer de l'Etat 5,000 tons of rails. Orders are not so plentiful as they were in the North of France, but the works have enough to keep them going for five or six months. Bars are quoted at 120s. 6d. per ton; joists, according to the width of flange, from 124s. 6d. to 140s. 6d.; best angles, 124s. 6d.; wide flat bars, 136s. 6d.; puddled sheets, 2mm. thick, 160s. 6d.; those of 3mm. and upwards, 144s. 6d.; and boiler plates from 168s. 9d. to 184s. 9d. per ton, according to quality. In the Ardennes the situation seems to be slightly better than it was in the previous week. The price of 120s. 6d. per ton is well sustained by the rolling mills, and the foundries are fully occupied. The contract for pipes for the Paris (Vigne and Verneuil) water supply, amounting to 3,400 tons, was adjudged on the 30th ult. in part to the Société d'Aubrives, and the remainder to the Société de Commentry-Fourchambault. In the Meurthe-et-Moselle and Haute-Marne districts there is no change to be noted.

COPPER, TIN, AND LEAD.—The official quotations for the past week on the Paris copper market were as follow:—Best Chilian bars, £59 5s.; ordinary Chilian bars, £57 5s.; ore (Chilian) in ingots, £59 15s.; and best selected, £60 18s. per ton. There has been no change in the price of tin with the exception of Cornwall, which is now quoted at £102 15s. per ton. Lead has improved slightly in value, the latest quotation being £13 5s. per ton.

THE LATE COLONEL LEBEL.—Colonel Lebel, the inventor of the rifle which has been adopted by the French Government, died on the 7th inst. at Vitre. After serving during the Franco-German war, and having been taken prisoner at Sedan, on returning to France he was appointed to the charge of a musketry school near Tours. He was afterwards appointed on the commission which was formed for the purpose of discovering a new form of gun, and was director of the Normal School of Shooting at Chalons when the gun of which he was the inventor was adopted.

ELECTRIC LIGHT INSTALLATION.—The Corporation of Saint Etienne invites tenders for the lighting of the theatre in that town. The cost of installation is estimated at £920.

ELECTRIC TRAMWAY.—La Société des Tramways de Paris et du Département de la Seine are about to start, on the 1st prox., a regular service of cars worked by electricity from the Rue Lafayette, near the Opera, to St. Denis, over a line having some very steep gradients. The rolling stock is to consist of twenty carriages, which are being constructed by Mr. George Averly, of Lyons, after an American model. They will carry fifty-four passengers and attain a speed of ten miles an hour.

LEAD IN ALSACE-LORRAINE.—A deposit of lead ore has just been discovered in the neighbourhood of Thann, near Mulhouse. A company has been formed, and experimental works have been commenced which are expected to give satisfactory results.

A SUBAQUEOUS TUNNEL.—The Western Railroad of France will, it is said, build a tunnel under the Seine, near Quillebœuf. The total length of the tunnel is 14,760ft.; 6,560ft. of this is through solid ground, and the tunnel will be driven by the usual methods. The 8,200ft. which passes under the bed of the river will be in a soft alluvial deposit, and will be built with cast-iron lining, circular in section.

BERLIN, 8th June, 1891.

THE IRON MARKET.—The Upper Silesian Works recently tendered at Breslau to supply 1,500 tons of rails at £6 4s. per ton. In February and March the Breslau tenders for rails were at £6 6s. 4d., and the last tenders at Bromberg were at £6 3s. 5d. The Laura Works tendered for 900 tons, and the Frieden Works for 550 tons at £6 4s. The United Royal and Laura Works tendered for 72 tons of outer fishplates, and 66 tons of inner fishplates, at £68 11s. per ton, and for 8 tons and 21 tons of cast-iron or welded bedplates at £61 4s. per ton. The Frieden Railway Construction Works have fixed the price of fishplates at £6 0s. 5d., and the Laura Works at £6 2s. 5d.

THE COAL MARKET.—Statistics given at the general meeting of the Holland Mining Company show an increase in the cost of production. The average wages paid for an eight hours' day were given as follows:—Hewers of rock, 4s. 11d.; hewers of coal, 4s. 7d.; timber and repairing work, 3s. 2d.; barrowmen and brakemen, 2s. 6d. The average of miners' wages is thus 3s. 6d. These figures show a rise of 16 per cent. in miners' wages as compared with 1889, and a rise of 39 per cent. as compared with 1888. The cost of production during 1890 has increased by 10d. per ton as compared with 1889, which is equal to a rise of 15 per cent. Of this increase, 6d. is paid in higher wages, 2d. in higher taxes, and the remainder for the increased price of materials. A contract for the supply of 50,000 tons of compressed fuel has been awarded by the State Railway management in Hanover to the Patent Fuel Union in Dortmund.—Important seams of coal have been discovered between Bayreuth and Neumarkt in Bavaria.

SALT INDUSTRY.—A company has been formed in London under the title of the Hanover Salt Company, with a capital of £175,000, in order to work the rock salt strata near Celle, in Hanover.

TRAFFIC ON GERMAN RAILWAYS.—For some time past complaints have been made both by manufacturers and by the general public as to the traffic management on the Prussian State Railways. A deficiency in the supply of waggons has often been felt by coal merchants, and numerous complaints are made as to the rates for passengers and goods. This unsatisfactory state of affairs on the Prussian railways has been attributed to the want of competition, and the excellent working of English railways has been adduced as a proof of this. The management of the three Berlin tramway companies in view of their increased traffic has been brought forward as a further proof of the benefits of competition. During the year 1890 the traffic in Berlin was as follows:—

	Thousands of Persons.
Great Berlin Tramway	121,250
Berlin-Charlottenburg Tramway	5,631
New Berlin Tramway	14,076
Steam Tramway	2,064
General Berlin Omnibus Company	19,193
New Berlin Omnibus and Parcel Delivery Company	6,928
Total	169,142

As the population of Berlin, including Charlottenburg, is 1,650,885, each inhabitant must have travelled on an average more than a hundred times. If these figures be compared with those of the passenger traffic on the Prussian railways, which shows a total of 250 million persons with a population of about 30 millions, it is seen that each person travels on an average 8⅓ times during the year. The railway traffic is, therefore, capable of being largely developed, since in Prussia there are, besides Berlin, twelve cities with from 50,000 to 100,000 inhabitants, and sixteen cities with over 100,000 inhabitants.

VIENNA, 8th June, 1891.

THE COAL MARKET.—Whilst the demand for coal, especially for industrial purposes, increases from day to day, the strike continues in some districts of the North-West of Bohemia. Those mines which are still in operation are the more actively employed, and there is every prospect that they will continue so. The North Bohemian Coal Mining Company made a profit of £17,346 5s. during the first four months of the current working year, which shows an increase of £3,265 4s. as compared with the corresponding period of the previous year. The Lankowitz Coal Company pays a dividend of 3 per cent. for the past year.

THE IRON MARKET.—The condition of the iron market shows little alteration, but a slight improvement is visible as regards pig iron and rolled iron. Prices are very favourable, and the demand for iron for constructive purposes continues active notwithstanding the advanced state of constructive works. Orders for railway rolling stock increase every day, so that works will be fully employed for some months to come. In Hungary, where there is still a large scope for various industries, the state of the market is encouraging, and many new works are under contemplation, whilst old works are being extended. There is every prospect that the favourable condition of the market will continue.

ELECTRICAL ENGINEERING.—Twenty-six Austrian firms, of which twenty-two firms are in Vienna, are taking part in the Frankfort Electrical Exhibition. Messrs. Ganz & Co., who are represented by the "Helios" Company at Cologne, and by whom their patents are taken out, will probably show some improvements in electrical tramways. The electrical department of this firm is to be extended, and the projected extension is nearly as large as the old works. Messrs. Kremenetzky, Mayer, & Co. have also completed an important extension of their works. These are marked evidences of the actual progress of this industry. Some annoyance is felt at Berlin by reason of the extension of the concession granted to the International Compressed Air and Electricity Company. The company has not paid a dividend this year, and will probably cease to attempt to establish itself in Vienna.

PRODUCTION OF SUGAR IN AUSTRIA.—In the month of April 62,400 tons of sugar were exported, and the home consumption was 24,861 tons. The production from August, 1890, to April, 1891, is given as follows, in tons of raw sugar:—

	1890–1891.		1889–'890.
Original stores	79,320	...	39,620
Net production from August to April	715,342	...	689,912
Exported	348,058	...	328,233
Home consumption	214,180	...	217,599

BRUSSELS, 9th June, 1891.

THE IRON MARKET.—The market shows some improvement, and manufacturers hope to maintain prices. Some important awards of contracts have been made during the past week. The Ougrée Steel Works have contracted for 290 tyres at £10 per ton, and Messrs. Cockrill for 800 tyres at the same price. The Société d'Estampage has contracted for 400 fishplates at £19 4s., and Messrs. Acoz for angle fishplates, iron at £6 3s., and steel at £7 3s. The tender for cramps has been awarded to the Northern bolt manufactories, and the tender for bolts to the Van Calk and Blanchisserie works. The market for raw material remains inactive. The rolling mills are employed in carrying out old orders, but new orders are scarce.

THE COAL MARKET.—The situation has improved, but there is some hesitation in dealing at present prices. The award of contracts for 430,000 tons of coal for the Belgian State Railways, which will take place on the 16th inst., will show the state of the market. If sellers should try to obtain too high a price, German coal will be introduced into Belgium, and soon cause a lowering of prices. The attempt to lower the price of coke has failed, and it is still quoted at 14s. 5d. per ton. During the first four months of the year, as compared with the corresponding period of 1890, the imports of coal have decreased, whilst the exports have been maintained. As regards coke, the reverse is the case.

	1890.	1891.
Import of coal ...	524,362 tons.	494,655 tons.
Import of coke...	10,200 „	48,859 „
Export of coal ...	1,430,017 „	1,486,704 „
Export of coke...	460,335 „	335,040 „

BRUSSELS AS A SEAPORT.—The important project of making Brussels a seaport has been under the consideration of the Department of Industries. A plan of the proposed canal on the scale of 1 to 500 has been made, and work is to be commenced on the western section. The construction of the harbour has been discussed, and the joining of the canal with the Ruppel has been considered by a committee of engineers. The lines of the canal have been planned, and it has been decided that it will be necessary to construct large embankments. Several syndicates are in course of formation in order to carry out the works, but an English syndicate which has been negotiating for the construction of the canal appears to have the best chance of success.

NEW TRANSATLANTIC LINE OF STEAMERS.—A new line of steamers between Belgium and Canada is about to be started by a company which has been formed for that purpose. As the commercial situation is very unsatisfactory, Belgian trade is trying to find an outlet in distant countries. The exports from this country during the first two months of this year show a diminution of 16 per cent. on those of the preceding year. Belgian trade might profit by the dispute which has arisen in Canada as to the proposed commercial treaty between that country and the United States.

A LARGE TEXTILE COMPANY.—Four of the largest textile weaving establishments at Alost have been amalgamated, under the title of the "Société Anonyme Union Textile." The firms which have become amalgamated are Messrs. Govaert Frères, M. Elias Cools, Messrs. L. De Ruddere et Cie., and Veuve Borremaus-Van Melkebeke.

DÜSSELDORF, 9th June, 1891.

THE IRON AND STEEL MARKET.—The demand for iron and steel has rather increased, but, notwithstanding this favourable circumstance, prices are in general as low as before. The slight increase in the price of Thomas (basic) pig, which was mentioned last week, has strengthened the market, while the upward movement of the Glasgow market has been without influence on business. All brands with which the English market enters into competition have maintained their former prices without change. Manufacturers of plates and sheets are fairly well employed. Wrought-iron boiler plates are quoted from £8 6s. 6d. per ton to £8 11s. 5d., and ordinary plates at about £7 7s., while Siegen sheets are from £6 7s. 4d. to £7 2s. Bar iron is quoted at £6 17s., and makers are anxious to obtain new orders. The State Railway management at Elberfeld invites tenders for 2,000 tyres and 1,000 waggons, and makers of railway material and rolling stock are well employed. The same may be said of the bridge building works; the Gutehoffnungshütte have just got an order for 560 tons for bridges over the Saale. There is no news at present of a prolongation of the rail and girder syndicates, whose agreements terminate towards the end of this year.

THE COAL MARKET.—The coal market continues very active. In the public award of contracts at Altona the prices asked for locomotive coal were, in few instances, below 10s. 3d. per ton, and only 8,000 tons were offered at 10s. On behalf of English firms there were tenders for 240,000 tons from 12s. 9d. to 16s. 8d. c.i.f. Hamburg Harbour. No decision has yet been arrived at. It may be estimated that the freight from the Ruhr district to Hamburg is on an average about 5s. The shipments of coal on the Rhine for Southern Germany are unusually brisk.

NEW STEEL WORKS.—Some new steel works, the "Westfälische Stahlwerke," were opened recently at Bochum. The manager is Mr. Koehler, who was formerly in the service of the "Westfälische Stahlindustrie." The new works has two converters, of ten tons capacity each, and a

Digitized by Google

row of basic open hearths. The chief manufacture will be that of rails.

A Deep Boring.—A hole has recently been drilled by a diamond drill near Schladebach, in Saxony, to a depth of 4,560ft., for the purpose of testing a coal formation. Three and a half years were occupied in drilling the hole, which is about 11in. in diameter at the top and 2in. at the bottom.

AMSTERDAM, 8th June, 1891.

Important Harbour Works at Amsterdam.—The Amsterdam Chamber of Commerce has just presented to the Town Council a memorial in support of the scheme, prepared by the civil engineers, Messrs. Tak van Poortvleit, Van de Wall Bake, and Hendrichs, for the extension and amelioration of the present harbour works in the Dutch capital. The main features of the scheme are the development of the existing jetty and warehouses, constituting what is called the Commercial Quay, the building of docks and new warehouses around it, and the transfer of the railway, now running on the jetty, to a viaduct to be constructed alongside the Prins Hendrikkade, or Parade, which bounds the north side of the city. To the eastern docks the removal of the railway will be of great assistance in developing navigation, as the constant closing of the railway bridge over the entrance is a serious hindrance. In the memorial of the Chamber of Commerce it is pointed out that the chief cost of the new works will have to be borne by the State and the railway companies concerned, as their property will thereby be benefited to a considerable extent, more particularly the State, as the Royal dockyard and Government wharves are now seldom accessible, owing to the railway line.

The Telephone in Holland.—The shareholders of the Dutch Bell Telephone Company have held their annual meeting. The report laid before them was of a very satisfactory nature. Business has much increased, both in Holland and in the Dutch East-Indian towns where the company holds concessions. A dividend of nearly 8½ per cent. on the share capital has been announced by the Board.

The Goldfields of Guiana.—In the dispute with France as to the right boundaries of the goldfields in French and Dutch Guiana, Holland has recently scored an important victory. The Emperor of Russia, acting as arbitrator in the dispute, has given his award, which practically acknowledges the rightful claim of Holland to the whole of the disputed territory between the Lawa and the Tapanahoni rivers, subject only to the private rights of individual Frenchmen, already legitimately acquired. Henceforward the Lawa River must be considered the boundary between French and Dutch Guiana.

STOCKHOLM, 6th June, 1891.

The Large Gefle Strike.—This strike has now been compromised, and its conclusion has caused much satisfaction. The matter in dispute has been referred to a committee of five persons, of whom each side chooses two, and these four the fifth. Pending the decision of the committee, the Kopparberg-Hofors Company partly regulates wages by the men's price list, whereas the Korsnös Company adheres partly to last year's price list.

The State Telephones.—The development of the Swedish State telephone system continues at a rate to which probably few parallels can be found—at least, in Europe. A Government grant of £33,300 voted last October has already been spent, chiefly in the purchase of private telephone companies at Arboga, Sala, Eskilstuna, Karlshaum, Karlskrona, Romilby, and Sölvesborg, and in extending other telephonic systems. The number of telephones has thus been increased from 3,800 to 5,500, which means an addition of about 45 per cent., and corresponds to a calculated increase in the gross receipts from £20,220 to £30,555, or rather more than 50 per cent. These extensions will now be followed by numerous others, calculated at an expenditure of about £26,100, in addition to which their connection with the large system of State telephones will entail a further outlay of about £8,880, making a total of £34,980. The acquirement of these telephone companies will increase the number of subscribers by about 2,000, and the yearly receipts by about £8,330, but it is confidently expected that a very material subsequent addition will follow. Other localities have applied to the State Telephones management for connection with their system, including some important centres in the mining districts, such as Nora, Lindesberg, Kopparberg, Ramsberg, Ludvika, and Smedjebakken. The constant increase of subscribers in Stockholm makes large extensions necessary. The sum required for all these new extensions is estimated at £55,500.

The Ystad Match Manufactory.—The match works at Ystad, which belong to the Swedish Match Company, Ld., and which have been closed since this company's stoppage in 1889, have now been started again with about the same number of workpeople as before.

Removal of Duty on Ships.—The fact of the duty on ships having been done away with is likely to benefit English builders, who have, for the last year or two, been almost debarred from competing with Swedish builders. A Wiken syndicate has, for instance, decided to order a 900 tons vessel in England at a price of about £10,000, and other orders are sure to follow.

COPENHAGEN, 6th June, 1891.

The Bacon Factories.—The contemplated amalgamation of all the Danish bacon factories, co-operative as well as private, does not altogether seem to meet with the approval of those interested. Several of the factories have declined to accept it in its present shape, and it is specially urged that the interest of the farmers is not sufficiently considered. In order to remove this objection several representatives for the various agricultural societies have been invited to join the committee.

The Frederiksholm Lime and Brick Works.—The Frederiksholm Lime and Brick Works, situated near Copenhagen, have recently considerably increased their plant, which makes it possible to complete the manufacture of bricks in a shorter time, whereby the cost is reduced. During last working year the sales amounted to £50,928, and the profits to £7,229. A sum of £1,660 was added to the sinking fund, and a dividend of 6 per cent. was declared.

The Ringkjobing Fjord.—A committee has now been formed to consider the question of an additional entrance to the Ringkjobing Harbour, on the west coast of Jutland. It is proposed to make a cutting through the Nordevand and the Godel dam.

MADRID, 8th June, 1891.

The Altos Hornos Company.—At a meeting of the Altos Hornos Company of Bilbao, which was held last month, a satisfactory report was presented. During the year 1890, 26,826 tons of pig iron, 21,253 tons of rails, and 26,530 tons of bar iron were sold by the company. The net profits were £36,580, and, after allowance had been made for depreciation, and a sum had been placed to the reserve fund, a dividend of 7 per cent. per annum was declared, and an extra sum of £1,200 was to be divided among the shareholders. It was decided to make a call of 10 per cent. on the shares, which is to be applied to the purchase of land and to the establishment of a battery of coke ovens. It seems probable that the Coppée system will be adopted, as was done at the works of Señor Martinez Rivas.

Electric Incandescent Lamps.—Gas being very expensive in Madrid, it seems probable that the electric light will be used here more extensively than in any other town of the same size. The number of incandescent lamps required for renewals in Madrid and neighbouring towns will no doubt be sufficient to employ a factory giving an output of 2,000 lamps daily. Imported lamps cannot be sold here under 2s. 9d. each, even if the importer be satisfied with a small profit, and the lamps could be made here as cheaply as in any other place. The law requires industrial use of a patent within two years of the granting of the patent, otherwise the patent becomes void, and under this condition none of the patents relating to incandescent lamps are now valid in this country. Any person could now apply for a five years' patent to work Edison's, Swan's, or any other lamp, and at present there is no manufactory of electric incandescent lamps here.

Privileges of the Banco de Espana.—A considerable and well-grounded agitation has been carried on among the industrial and commercial classes against the granting of certain privileges to the Banco de España in return for a loan made to the Government by that bank. Owing to this movement the Government has been completely defeated, and the proposed law will be considerably altered.

Pyrites Mines.—An offer to rent the pyrites mines of El Castillo de los Guardias for five years at a rental of £10,000 has been accepted. In order to make the working of these mines successful, a railway to Seville must be constructed, or some arrangement must be made with the Rio Tinto Railway Company.

The Rio Tinto Company.—The construction of a railway from Belmez to join the Zafra and Huelva Railway, and the supposed purchase of coal mines at Belmez by persons connected with the Rio Tinto Company, seem to indicate that some change is to be made in the management of this company. The company has proposed for some time past to erect blast furnaces in order to deal with the hematites of this rich district.

NEW YORK, 30th May, 1891.

Two Proposed Bridges.—The Vice-President of the New York Central Road has stated that the company will make a bridge across the St. Lawrence River from Cape Vincent to Wolfe Island, and from Wolfe Island to Kingston. With this bridge and an agreement with the Canadian Pacific Railroad, trains can be run through from British Columbia to New York. A charter has been applied for to bridge across the Niagara River, near the whirlpool rapids, for electric or steam railway purposes. It is proposed to construct an electric railway from American Park to the river bank, thence across the proposed bridge to the Canadian side, and finally to Canadian Park. This is the principal object in view, but the Bill will make the construction of a steam railway possible.

A New Valve Gear for Locomotives.—Mr. W. J. Lewis, of St. Louis, is introducing a new valve gear for locomotives which does away entirely with links, eccentrics, eccentric straps, and rocking arms. The gear has been successfully applied to a locomotive on the "Cotton Belt" Railway.

Electric Train Signalling.—Mr. W. P. McCann, of Sterling, Ill., has brought out a device for signalling railroad trains between stations, transmitting messages by signal in mines, and calling policemen to patrol boxes, and for any other purpose of a similar nature. The plan for signalling trains is to have incandescent electric lights placed every mile between stations. In case it is necessary to signal a train after leaving one station and before it reaches the next, then, by an arrangement of switches, the light is turned on in any lamp desired. In case of accident, or of a train running on another's time, all the lights between the two stations would be turned on, and the first one seen by the engineer would be a sign to stop. Telephones would be placed on every electric light pole, and the engineer could then communicate with the nearest station and learn the orders which it was desired to communicate.

New Tinplate Company.—A company has been organised, with a capital of £200,000, to be known as the Welsh-American Tinplate Company. Works for the manufacture of tinplate are to be erected in Eastern Pennsylvania, the plans embracing the building of four tin mills, with a productive capacity of 2,000 boxes per week. Ultimately the plant is to be increased to twenty mills, with an annual capacity of 500,000 boxes.

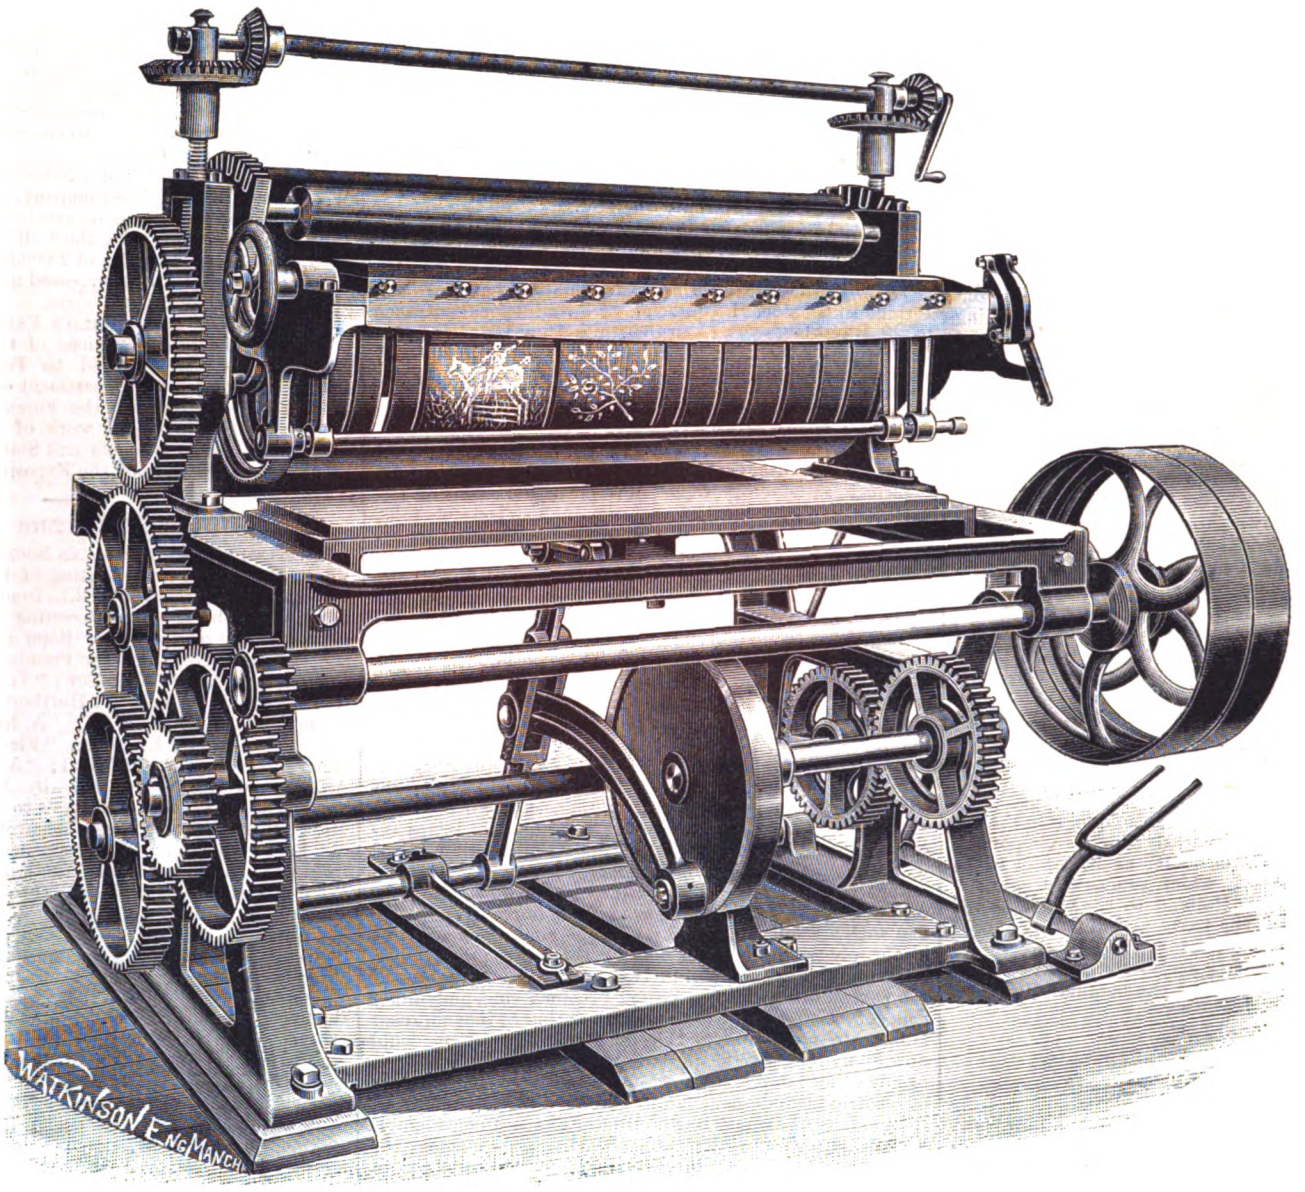
Forestry at the World's Fair.—Not the least important of the great divisions of the World's Columbian Exposition is that devoted to Forestry. Mr. W. I. Buchanan, Chief of the Department of Agriculture, who is at present in charge of the Forestry Department, has entered actively upon the work of enlisting the various timber and lumber interests and State Forestry Bureaus in this important feature of the Exposition.

PHILADELPHIA, 29th May, 1891.

Meeting of the American Society of Mechanical Engineers.—The next meeting of this Society, which is to be held at Providence, R.I., from June 16th to 19th, promises to be a very interesting one. The following papers will be read:—"Two Rope Haulage Systems," by Mr. R. Van A. Norris; "The Premium Plan of Paying for Labour," by Mr. F. A. Halsey; "Test of a Triple-Expansion Engine," by Mr. J. P. Hurthorn; "A Belt Dynamometer," by Mr. S. P. Watt; "A New Belt Testing Machine," by Mr. G. I. Alden; "Flexure of Thin Elastic Rings," by Mr. De V. Wood; "Applications of Hirn's Analysis to Engine Testing," by Mr. R. C. Carpenter; "Applications of Hirn's Analysis to Multiple Engines," by Mr. C. H. Peabody; "Notes Regarding Calorimeters," by Mr. R. C. Carpenter; "Jet Propulsion," by Mr. J. B. Webb; "Performance of a Steam Reaction Wheel," by Mr. J. B. Webb; "Heat Transmission through Cast-iron Plates Pickled in Acid," by Mr. D. Royse; "Steam Engine Efficiencies," by Mr. R. H. Thurston; "Effect of the Steam Jacket on Cylinder Condensation," by Mr. W. W. Bird; "Method of Dividing an Index Plate into 1,000 Equal Parts," by Mr. W. A. Rogers; "A Machine for Cutting Perfect Screws," by Mr. W. A. Rogers; "Steel Castings," by Mr. H. L. Gautt; "Manganese Steel," by Mr. H. M. Howe; "Comparison of Economy of Compound and Single Cylinder Corliss Engine," by Mr. D. S. Jacobus, "Performance of a Pumping Engine against a Head of 2,000ft. of Water," by Mr. J. E. Denton; "A Blast Furnace Blowing Engine," by Mr. F. W. Gordon: "Some Experiments with a Screw Bolt," by Mr. J. McBride; "Mechanical Stokers," by Mr. W. R. Roney. The Society has also arranged several excursions and visits to the important industrial establishments in the neighbourhood.

End of the Great Coke Strike.—Mr. Wise, a master workman, has advised all strikers to go back to work, and the strike is practically over. The week before the strike the production of the region was 101,700 tons, last week it was over 60,000 tons. It is estimated that the loss occasioned by the strike both to manufacturers and men will be between £800,000 and £1,000,000. The manufacturers are carrying out their threat that when the strike was over they would punish the leaders, and over 1,000 men, who were leaders or active committeemen, have been refused work.

Naval.—The Naval Ordnance Bureau has carefully tested and accepted 300 steel armour-piercing projectiles of 6in. calibre, made by the Carpenter Steel Company, of Reading, Pa.



Renewal of the Standard Works Strike.—When the strike at the Standard Steel Castings Company was settled a few days ago, it was with the understanding that most of the old hands would be taken back. This was not done, only a very small proportion of the original strikers being selected. The men have decided to continue the strike indefinitely.

Telephone Company.—A company has been formed under the title of the Illinois Pulsion Telephone Company, at Chicago, Ill. The corporation has for its object the building and leasing of a line of private telephones throughout Illinois. The State right for the use of the Pulsion or acoustic system of telephones, which is claimed to be superior in many respects to the Bell system, has been secured from the New Hampshire Company, owners of the patent. The capital stock of the new company is £100,000.

Railroads.—The report of the Michigan Southern Railroad for 1890 showed gross earnings exceeding £4,000,000, the largest in its history. Articles of incorporation have been filed with the Secretary of the State of Illinois of the Muscatine, Rock Island, and Peoria Railroad Company, capital £400,000. The lowest rate on record, 5c. per bushel, is being charged for carrying wheat from Chicago to New York. The grain goes by the lakes to Buffalo, thence to tidewater by the Erie Canal. Of the 5c. charged, the lake boats get 1½c., the Buffalo elevators ⅞c., and the Erie Canal boats the remainder.

THE "ARGUS" CLOTH STAMPING MACHINE.

General View.

THE "ARGUS" CLOTH STAMPING MACHINE.

The machine which we illustrate above is constructed for the purpose of stamping designs or trade marks on piece goods, which has hitherto been done by hand. It consists of a revolving cylinder, on which is fastened the metal blocks of the design or pattern to be stamped, a sliding table, which works directly beneath the revolving cylinder, and a disc crank for working the sliding table. The machine is power driven by means of the usual fast and loose pulleys, which are fixed to a cross shaft at the back of machine. On the opposite end of the driving shaft is fastened a small pinion wheel, which gives motion to all the working parts. On one side of machine is arranged a train of wheels (in direct communication with the pinion mentioned above), one portion of which gives motion to the revolving cylinder, and the other portion motion to the sliding table by means of a cross shaft underneath. This cross shaft gives motion by means of a pair of spur wheels to a second shaft, on which is fastened a disc crank. This crank is coupled to the sliding table by means of a connecting rod and a series of levers, thereby giving motion to the table and a speed equal to the surface of the cylinder. The bearings of the cylinder are constructed so that the cylinder may be raised or lowered at will, according to the thickness of the piece goods to be stamped.

The colour feeding arrangement is at the back of the machine, and consists of a roller and ductor, which can be regulated by means of suitable screws, &c. The motion of the colour roller is obtained from the end of the cylinder shaft by means of a cam, ratchet, and pawl, the throw of the ratchet being regulated so as to give more or less colour as required. Between the colour roller and the cylinder is suspended a composition or treacle roller, which transfers during every revolution of the cylinder a sufficient quantity of colour from the feed roller to the colour slab. The latter occupies about one-third the circumference of the cylinder, and is opposite to where the metal blocks or design is attached. The colour is transferred from the slabs to a series of composition rollers, which are arranged circumferentially round the cylinder, and these rollers again transfer the colour to the metal blocks.

The method of fastening the blocks or designs to be stamped is a very neat one, and allows a separate design to be arranged while one is at work. This is carried out by means of duplicate circular thin steel plates, which are made to fit the cylinder. After the design has been arranged, the blocks being used may be taken off, and new ones adjusted in a few minutes.

The advantages of this machine consist in simplicity of construction, facility of working, moderate size, and comparative cheapness. The stamps used are less expensive than the old copper wire stamps when the latter are somewhat complicated in design. The method by which the stamps for this machine are produced ensures an accurate reproduction of any special Oriental or other characters on the design which may be required. The speed at which the work can be done largely exceeds that of hand stamping.

Particulars of this machine may be obtained from Messrs. J. C. Norbury & Sons, 108, Portland Street, Manchester.

CLYDE SHIPBUILDING FOR MAY.

For the first time since January the output was exceeded in point of tonnage by the new work booked, and quite an impetus has been given to the shipbuilding industry in the lower reaches of the river by the large orders secured by builders there during the month. In the middle and upper reaches of the river, however, the existing state of matters is anything but gratifying, and the orders booked in these districts just balance the output. Altogether the new work contracted for aggregates fully 22,000 tons, and of this amount about 14,000 tons were secured by firms in Greenock and Port Glasgow. Messrs. Caird & Co. were particularly fortunate, they having received instructions to build three large steamers of 9,500 tons—two, of 3,000 tons each, for the Peninsular and Oriental Steam Navigation Co., and one, of 3,500 tons, for the Gulf Line, which will practically be a repeat of the "Gulf of Bothnia," the particulars of which are mentioned below. Messrs. William Hamilton & Co., Port Glasgow, and Messrs. Russell & Co., Greenock, each received instructions to build a steel sailing ship of 2,200 tons; an order for a 2,500-ton sailing ship was placed with the Fairfield Shipbuilding and Engineering Co., Govan; while Messrs. Barclay, Curle, & Co., Whiteinch, and Messrs. Chas. Connell & Co., Scotstoun, are each to build a steel sailing ship of 2,000 tons.

The output of work reached a total of 20,024 tons, of which 8,546 tons were contributed by sailing vessels and yachts.

The following are the particulars of the vessels launched:

Single-screw Steamers.

"Alice Taylor," steel, 600 tons, 1,400 i.h.p., built by Messrs. William Hamilton & Co., Port Glasgow, and engined by Messrs. George Clark, Sunderland, to the order of Mr. Robert Taylor, Dundee.

"Asteria," steel, 500 tons, 680 i.h.p., built by Messrs. Scott & Co., Bowling, and fitted with triple-expansion engines by Messrs. Muir & Houston, Kinning Park, for the coasting trade of Mr. William Robertson, Glasgow.

"Diamond," iron, 156 tons, 300 i.h.p., built by Messrs. Mackie & Thomson, Govan, and engined by Messrs. Muir & Houston, Kinning Park, for the North Sea fishing trade of the Kingston Steam Fishing Company, Hull.

"Earl of Devon," sister ship to the "Diamond," by the same builders, and for the same owners.

"Elcano," steel, 50 tons, 130 i.h.p., built by Messrs. J. Fullerton & Sons, Paisley, and engined by Mr. William Kemp, Govan, for Spanish owners.

Digitized by Google

"Grouse," steel, 360 tons, built and engined by Messrs. Caird & Co., Greenock, for the Clyde and Irish trade of Messrs. G. & J. Burns, Glasgow.

"Gulf of Bothnia," steel, 3,500 tons, 5,000 tons deadweight capacity, 2,000 i.h.p., built and fitted with triple-expansion engines by Messrs. Caird & Co., Greenock, for the general trade of the Greenock Steamship Company.

Hopper barge, steel, 300 tons, 350 i.h.p., built and engined by Messrs. William Simons & Co., Renfrew, for the Preston Corporation.

Hopper dredger, 400 tons, 300 i.h.p., built and engined by Messrs. William Simons & Co., Renfrew, for the Indian Government.

"Kweilin," steel, 1,800 tons, 1,200 i.h.p., built and fitted with triple-expansion engines by Messrs. Scott & Co., Greenock, for the China Navigation Company.

"Ruby," sister ship to the "Diamond" and "Earl of Devon," by the same builders, for the same owners.

"Siphora Worms," steel, 1,600 tons, 1,400 i.h.p., built and fitted with triple-expansion engines by Messrs. Lobnitz & Co., Renfrew, to the order of Messrs. Worms, Josse, et Cie., Paris.

"Tramandaby," steel, 910 tons, 700 i.h.p., built and fitted with triple-expansion engines by Messrs. Scott & Co., Greenock, to the order of the Companhia de Paquetes Brazil Oriental, of Rio de Janeiro.

Twin-screw Steamers.

"Clutha No. 9" and "Clutha No. 10," each of 150 tons, built by Messrs. Murray Brothers, Dumbarton, and fitted with compound engines by Messrs. Matthew Paul & Co., Dumbarton, to the order of the Clyde Navigation Trustees, for their harbour service.

"Tynwald," steel, 1,000 tons, built and engined by the Fairfield and Engineering Shipbuilding Company, Govan, for the Isle of Man Steam Packet Company.

Paddle Steamer.

"Lorna Doone," steel, 350 tons, built by Messrs. Napier, Shanks, & Bell, Yoker, and fitted with compound diagonal engines by Messrs. D. Rowan & Co., Glasgow, for Messrs. Edwards, Robertson, & Co., Cardiff, for service in the Bristol Channel.

Sailing Vessels.

"Cromdale," steel, 1,850 tons, built by Messrs. Barclay, Curle, & Co., Whiteinch, to the order of Messrs. Donaldson & Rose, Aderdeen.

"Earl of Dunmore," steel, 2,200 tons, built by Messrs. Russell & Co., Greenock, to the order of Mr. J. D. Thompson, Grangemouth.

"Samaritan," steel, 2,000 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, to the order of Messrs. William Thompson & Co., St. John's, New Brunswick.

"Thistle," steel, 2,300 tons, built by Messrs. Chas. Connell & Co., Scotstoun, to the order of Captain J. D. Clink, Greenock.

Yachts.

"Dora," 10-ton centre-board yacht, built by Mr. James Adam, Gourock, for Messrs. R. & B. Allan, Glasgow.

"Irene," composite, 40-ton cutter, built by Messrs. A. & J. Inglis, Partick, to the order of Prince Henry of Prussia.

"Kite," wood, 13-ton cutter, built by Messrs. Fife & Son, Fairlie, for Mr. J. H. Lister.

"Lahloo," wood, 5-ton cutter, built by Mr. J. Ninian, Largs, for Mr. J. W. M'Lintock.

"Myrta," wood, 5-ton lugger, built by Messrs. Fife & Son, Fairlie, for Mr. W. C. Connell.

"Thalia," composite, 59-ton cutter, built by Messrs. Fife & Son, for Mr. J. A. Inglis, Glasgow.

"Thelina," wood, 5-ton lugger, built by Messrs. Fife & Son, for Mr. John Connell.

"Vashti," wood, 5-ton lugger, built by Messrs. Fife & Son, for Mr. P. M. Inglis.

"Volva," wood, 8-ton cutter, built by Messrs Fife & Son, for Mr. Geo. Watson.

In addition to the above the Abercorn Shipbuilding Company, Paisley, shipped to China two composite sailing vessels of 23 tons each, and Messrs. Alley & M'Lellan, Polmadie, shipped to the River Plate a steam launch of 50 tons.

Notices of Meetings.

THIS WEEK.

Royal Institution.—Friday, June 12th, at 9 p.m. Lecture on "The Rate of Explosion in Gases," by Professor H. Dixon, F.R.S. Saturday, June 13th, at 3 p.m. Lecture on "The Scientific Study of Decorative Colour," by Professor A. H. Church, F.R.S.

Physical Society.—Friday, June 12th. Papers to be read: "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power," by Professor W. E. Ayrton, F.R.S., and Dr. W. E. Sumpner; "A Clock for Pointing out the Direction of the Earth's Orbital Motion in the Ether," by Professor O. Lodge, F.R.S.; "Some Experiments with Leyden Jars," by Professor O. Lodge, F.R.S.; "The Construction of Non-inductive Resistances," by Professor W. E. Ayrton, F.R.S., and Mr. Mather.

NEXT WEEK.

Royal Statistical Society.—Tuesday, June 16th, at 7.45 p.m. Paper to be read: "Results of the Recent Census, and Recent Death-Rates in the Largest English Towns," by Mr. N. A. Humphreys.

Royal Institution.—Wednesday, June 17th, at 4 p.m. Faraday Commemoration Lecture by Lord Rayleigh, F.R.S.

Society of Engineers.—Wednesday, June 17th. Visit of members to the Linde British Refrigeration Company's Ice Works at Lower Shadwell and the City and South London Electric Railway Company's Depôt at Stockwell.

Royal Meteorological Society.—Wednesday, June 17th, at 7 p.m.

Chemical Society.—Thursday, June 18th, at 8 p.m. Papers to be read: "The Action of Sulphuric Acid on Dehydracetic Acid," by Mr. N. Collie; "The Refractive Power of Certain Organic Compounds at Different Temperatures," by Dr. W. H. Perkin, F.R.S.

PRICES CURRENT, 10th June, 1891.

Quotations at per ton, unless otherwise specified.

" Australian	93	15	0	"	94	5	0
" English Ingots	97	10	0		.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: Since our last report the market has been fairly steady, although values of raw have been variable. Current quotations for Chili bars, however, are practically the same as this day week, to-day's prices being £55 2s. 6d. to £55 10s. cash. Manufactured continues firm at £66 to £67, "strong."

Tin has advanced during the week, but to-day the market has rather a weaker tendency.

Lead has improved, and there is a little better inquiry.

Spelter has advanced considerably, and prices are higher on the Continent than here on account of a brisk demand for manufactured zinc. Stocks are small everywhere, and all the smelters have their production sold some months ahead, so that prices are likely to advance further.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Bleaching powder and caustic soda continue to move off steadily at unchanged prices, and soda ash is in good demand. There is not much business passing in sulphate of ammonia, but the market is steady. Crude carbolic is again weaker, and there is no disposition to purchase except at figures much below those asked by sellers. Benzoles are also lower. Caustic potash is firm; carbonate of potash a little easier. Sulphate of copper is yielding slightly for spot delivery. Yellow prussiate of potash continues firm and in good demand.

An Extensive Exhibit.—Messrs. Siemens & Halske have sent us a little volume of 150 pages devoted to a description of the various items of their exhibit at Frankfort. They exhibit everything electrical from a central station dynamo to a telephone, and their work seems to cover the whole range of electrical industry. We will refer to their exhibit more fully in a later issue.

We have received from Messrs. Richard Frères, of Paris and London, a copy of their new illustrated Catalogue of Measuring, Controlling, and Self-Registering Instruments for Scientific and Industrial Purposes. The catalogue is divided into three parts—viz., instruments for engineering purposes, electrical purposes, and meteorological purposes, and particulars are given of all the firm's well-known specialties.

HOME INDUSTRIES.

LONDON, 11th June, 1891.

The Money Market.—The abandonment of the attempt to maintain rates to protect the Bank reserve has been followed by a complete breaking away of the money market, and considerable withdrawals of bullion are likely to take place. Undoubtedly the greater ease in the market has been very welcome in many quarters, but there are misgivings that we may have yet to pay dearly for assuming too quickly that the situation was quite safe. The fear of a possible call on the Baring guarantors has been set at rest. The Bank of England makes it clear that not only is no call probable now, but that under no circumstances is one likely to be made. The stock markets have been uninteresting and featureless. The settlement, which occupied the greater part of the week, disclosed no essential change in the character of the account open, though continuation rates were generally easier through the greater cheapness of money. Consols have been weakened by fears of gold exports. The Indian sterling loans have been influenced by the issue of a new loan, which, though successful, tended to bring down the prices of the existing stocks. Foreign bonds have shown a tendency toward strength, though no one puts much faith in the permanent firmness of such securities as Spanish and Portuguese. The market for Argentines is uneasy, with no real firmness, but occasionally shows a tendency to rally. Home railways remain quiet and featureless, and, until a revival in Wall Street takes place, no well-sustained movement can be looked for in Americans. The minor markets present no feature, those for mining and industrial shares being almost wholly neglected.

Institute of Marine Engineers.—At a meeting of the Institute of Marine Engineers, held on the 2nd inst., under the presidedcy of Mr. F. W. Wymer, Mr. Gray continued his lecture on "The Metacentric Elements of Stability." Mr. Gray said that the subject of his lecture could be well studied in Mr. White's "Manual of Naval Architecture," and his object had been merely to induce the members to read up the subject. Captain McKirdy said that it would be desirable if some simple method could be given whereby a captain could ascertain how a vessel's stability is being increased or reduced while she is being loaded. It is proposed to resume the session for the reading of papers in September, when it is expected that Mr. James Weir will read a paper on "The Economy of the Marine Engine."

The Royal Observatory.—On the 6th inst. the annual visit of the Board of Visitors to the Royal Observatory took place, and a large number of persons accepted the invitation of the chairman, Sir W. Thomson, to inspect the instruments. Among those present were Sir George Airy, the former Astronomer Royal, and Dr. Gill, the director of the Cape Observatory. During the past year a transit room has been erected in the courtyard, and an octagonal tower at the south end of the grounds. The instruments used for the determination of longitudes will be placed in the transit room, which will be also used for the instruction of naval officers in the methods of determining the latitude and longitude of maritime stations. The octagonal tower will be used as a physical observatory. The 28in. refractor which is being constructed for the observatory by Sir H. Grubb is almost completed. The Astronomer Royal suggests in his report that the present buildings should be extended, so as to make the observatory worthy of its important position.

Fothergill Prize of the Society of Arts.—Under the will of Dr. Fothergill (1821) funds were bequeathed for the offer of medals for subjects, in the first instance, relating to the prevention of fire. A Society's gold medal, or £20, is now offered for the best invention having for its object the prevention or extinction of fires in theatres or other places of public amusement. In cases where the invention is in actual use, reference should be made to places where it could be inspected. A full description of the invention, accompanied by such drawings or models as are necessary for its elucidation, must be sent in on or before the 31st December, 1891, to the Secretary of the Society of Arts, John Street, Adelphi, London. The Council reserve the right of withholding the prize, in case there is nothing in their opinion deserving the award, or sufficiently complying with the conditions of the competition.

Faraday Centenary.—H.R.H. the Prince of Wales has fixed 4 p.m. on the 17th inst. for the delivery by Lord Rayleigh of the first of the two lectures in connection with the centenary of the birth of Michael Faraday, and 9 p.m. on the 26th inst. for the second of the lectures, which will be given by Professor Dewar.

Shipments of Wine.—Messrs. J. R. Parkington & Co. state that the shipments of port for May amounted to 8,695 pipes (Great Britain, 3,372 pipes), making 38,189 pipes for five months, against 37,710 pipes in 1890. The sherry shipments were 5,124 butts, making 28,172 butts for five months, against 26,521 butts in 1890.

Royal Meteorological Society.—The offices and library of this Society have been removed to more commodious rooms at 22, Great George Street, Westminster, S.W., to which address all communications should be forwarded.

The Society of Architects.—It is proposed that the annual excursion of this Society shall this year be made to Belgium, and be extended over a fortnight. It is intended that the party will travel *vid* Dover to Ostend, thence to Bruges, Ghent, Brussels, Louvain, Malines, Antwerp, Liège, Namur, Mons, Tournay, Oudenarde, Courtray, and home from Ostend. The secretaries will be glad to hear from any members who intend to join the party.

MANCHESTER, 11th June, 1891.

The Ship Canal.—It has been officially announced that it is expected that the Ship Canal will be opened for traffic as far as Ellesmere Port during July, and that the River Weaver traffic will be taken in a short time afterwards. This indicates a considerable advancement of the works, which are making rapid progress throughout the section. The railway diversions are approaching completion, some of the bridges being in a very forward condition. The Manchester City Council has adopted a resolution that the number of directors should be fifteen instead of twelve, of whom five should be members of the Council or nominated by it. It was resolved to endeavour to get a clause introduced into the Bill before Parliament to that effect.

New Meteorological Observatory. — The City Council has determined to establish an observatory on a plot of land owned by it in one of the crowded and populous districts in the city. Hitherto all the meteorological observations made in Manchester have been obtained in the suburbs, and it is thought they are more or less misleading as to the actual conditions prevailing within the city. A very complete set of instruments has been fitted, and in view of the recent results obtained by analysing the rain falling in the city, and the large percentage of sulphuric acid found therein, valuable results will probably be found to follow the observations taken.

The Salt Trade.—The owners of salt mines who are at present outside the bounds of the Salt Union, Ld., have agreed to take joint action to protect their interests, and a committee has been appointed to arrange with the directors of the Salt Union a basis for unity of action.

The Manchester Technical School.—Sketch plans for the new building to be used for the above purpose have been submitted to the Council of the Whitworth Institute. A deputation of the Council are visiting the principal schools in France, Germany, and Switzerland, in order to ascertain any facts which may be useful in determining the construction of the building or the special subjects taught.

New Pier.—What is practically a new pier is being erected at Lytham from the designs of Mr. W. Trafford Gunson, by Messrs. De Bergue & Co., Ld., of Manchester. The works include a new jetty, a large pavilion, and a considerable extension of the promenade space. The Blackpool Corporation are about to erect a large tower similar to the Eiffel Tower, the plans for which have been accepted. The design is generally similar to the Eiffel Tower.

Union of Lancashire Dyers and Finishers.—A strong feeling of dissatisfaction prevails in the Manchester home trade at the action of the local dyers and finishers, who have formed a union and issued a new list, showing a substantial advance in prices. A sum has been deposited by each member of the union, and is, we are informed, liable to confiscation in case of any attempt at underselling.

Technical Evening Classes.—The Manchester School Board instituted, under the Technical Instruction Act, a series of evening classes, for the purpose of instruction in various technical subjects. A sum of £1,000 was last year allotted to the Board by the City Council, and a number of classes were organised, about which Mr. C. H. Wyatt, the clerk to the Board, has recently given some interesting particulars. The total number of students increased from 3,165 in 1889 to 5,933 in 1890, this arising undoubtedly from the increased facilities provided. During the past session 2,115 art students entered the classes, 1,957 took subjects connected with engineering and kindred industries, and 818 studied chemistry. In commercial subjects there were 7,788 students, as against 2,707 in the preceding year. The cost of the classes for the session was £2,458, and it is intended to expend, in the coming session, a sum of nearly £4,000. In view of the fact that this has been more or less of an experimental series, their success has been very marked.

The Linen and Jute Trades.—Business this week has scarcely been satisfactory. Linen yarns, which in ordinary times are consumed extensively in Kidderminster and other carpet centres, meet with a small sale, owing to the fact that carpet looms are only partially employed. The same remark applies to jute carpet yarns. The linen departments in the local home trade firms experience some difficulty in finding orders, and the results of the June and half-yearly stocktaking will probably show that the goods on hand exceed the quantity anticipated by buyers. For shipment there is not much business, and trade with the United States, according to the returns of Manchester agencies of American firms, is below the average. There has, however, been a steady demand for some of the Continental markets, but Australian business has fallen off considerably, and Canadian orders will probably not improve for some little time. There is a gloomy feeling generally, and, as will have been seen from the Board of Trade returns, the unfavourable outlook which has been noticed in these reports during the past few months has unfortunately been confirmed.

The Age of Half-timers.—Following the example of most of the operatives' associations in Lancashire the North-East Lancashire Weavers' Association has pronounced against any advance of the age at which children can work half-time. The feeling in favour of the present arrangement is almost unanimous on the part of the operatives, but we have found more than one manager of successful concerns doubtful about the wisdom of employing half-timers from an economical point of view.

GLASGOW, 11th June, 1891.

The Iron Market.—The state of excitement and uncertainty in the pig iron market last week still continues, although the legitimate demand is very small. The price of warrants at the beginning of last week was 59s., a price which had not been reached since January, 1890, when, after three months of brisk demand for shipment, the falling off in export orders brought the price down. The situation recently has been wholly different. Export and home trade are alike dull, production has increased, and the movements in prices have been brought about entirely by speculation. "Bears" in Glasgow and London had opened heavy accounts, and when they considered the moment opportune had insisted upon delivery of the warrants they had bought. Those sellers who had oversold were obliged to go into the market, and thus, while the "bears" acted as spectators, the price mounted rapidly in their favour. It would appear as though now all, or almost all, the iron bought by them were in the possession of the "bears," and thus the state of the market really depends upon the manner in which the unloading takes place. As it is understood that a large quantity of the iron they hold was bought by them at 42s., they can sell at a price below the present market rate, reduced as it has been by a sharp reaction, and yet make a handsome profit. If, however, they are too eager to realise a profit the market may be depressed until their margin disappears. At present the most sagacious speculators appear to be holding their hands, uncertain as to the course which events will take. It is reported that the "bear" speculations have been carried out by some of those who have been most strenuous in their opposition to the Pig Iron Warrants Bill.

Shipbuilding.—The Clyde shipbuilding yards are unusually destitute of new orders, many of them having their stocks less fully occupied than they have been for some years. On the 9th inst. Messrs. D. & W. Henderson & Co. launched the "Numidian," a steamer of 4,900 tons, for the Allan Line. The steamer "Scot," just built by Messrs. Denny Brothers for the Cape service, has quite fulfilled the expectations of the builders. The measured mile trials at Southampton realised a mean speed of 18·8 knots, the horse-power developed being 11,656. The "Scot," which will carry the mails from Southampton on 24th July, will be on view in the Thames in about a week, in order that she may be inspected by those interested.

The Threatened Shipbuilding Strike.—Although discussions and conferences are still proceeding, the dispute between the Clyde shipbuilders and their workmen is likely to be settled on the basis of a compromise. On the 8th inst., owing to some sections of the men being ignorant of the progress of the negotiations, work was practically at a standstill in several yards, but in some of these the difficulty was surmounted by the removal of the notices of reduction pending a settlement of the dispute. It is expected that a strike will be definitely averted by arrangements to be made at conferences to-day and to-morrow.

Engineering.—A pair of double-decker steel cages, the largest and heaviest of their kind in Scotland, have just been made by Messrs. Archibald Baird & Son, Clyde Steel and Engineering Works, Hamilton, for Messrs. John Watson, Ld., Earnock and Eddlewood Collieries. The cages are the first of this type turned out by a Scottish firm. Each is 6ft. ¼in. by 6ft. 11in. They are capable of raising daily from 1,300 to 1,500 tons of coal. Each cage weighs about 3 tons.

(From our own Correspondents.)

LIVERPOOL, 10th June, 1891.

The Timber Trade.—The arrivals from the British North American Colonies during the past month have amounted to close on 5,000 tons, against 6,476 tons in the corresponding month last year. Values remain unchanged, and the stocks are generally too heavy, although they have been considerably reduced. Both waney and square yellow pine have had little sale, buyers preferring to wait for the new imports. The stock of red pine is ample, and prices low. There has been a moderate import of New Brunswick and Nova Scotia spruce deals, with satisfactory deliveries; the stocks are large. The demand for red pine is limited, and stocks are small. The stock of Saxon pitch pine is moderate, and there has been a large consumption; the stock of hewn is light. There has been a good inquiry for first-class oak, but the stock is still heavy. The stock of elm has been reduced to a moderate compass, but there is no change in value. The consumption of ash is small, and the stock heavy. The late auction sales of mahogany were well attended, and full prices obtained. The arrivals during last month amounted to 1,825 tons, against 680 tons for the corresponding month of last year. The market is bare of Honduras, the cargo per "Ellisif" having been sold; Tabasco is in good demand, and the next arrivals will meet with a ready sale, the market being bare.

Digitized by Google

ELECTRIC LIGHTING OF LIVERPOOL AND TOXTETH.—The Bill to confirm the provisional order granted by the Board of Trade to the Electric Supply Company for extending their operations in Liverpool and the district, has passed unopposed through the House of Commons, £20,000 being required to be *bonâ fide* subscribed and appropriated.

PROPOSED GEOGRAPHICAL SOCIETY.—A preliminary meeting for the purpose of taking into consideration the advisability of establishing a Geographical Society for Liverpool was held on the 6th inst. The success of the Manchester Geographical Society has fully shown the usefulness of an association of this nature.

SHEFFIELD, 10TH JUNE, 1891.

THE IRON AND STEEL MARKET.—There is no improvement in the general condition of the iron and steel trades report. The price of raw materials and labour shows little, if any, signs of decreasing. Forging and rolling mills are working short time. The Rolling Mills Association has increased its discounts, which means that rolling will be done for less money.

ARMOUR PLATE TEST.—Messrs. Vickers, Sons, & Co., Limited, have had one of their 10½in. all-steel plates tested on board the "Nettle" at Portsmouth, with most satisfactory results. The shots were three "Holtzer" projectiles, and two "Palliser," each weighing 100lb. The first Holtzer projectile broke in the plate, the second rebounded broken, and the third rebounded intact. Both Palliser shots were broken up. The plate, which is similar to those being constructed for H.M.S. "Centurion," was not seriously damaged.

MARINE ENGINEERING.—There is an almost total absence of work in connection with shipbuilding. Nearly all the work undertaken by firms in connection with orders under the Naval Defence Act is completed, and casting and forging manufacturers are not so well employed as previously.

EDGE TOOLS.—There is a fair amount of trade in edge tools of most kinds. Farmers are ordering scythes, and other agricultural implements, for the hay harvest, while the quantity of sickles sold proves that reaping machines are either unknown or difficult of use in some parts of the world.

CUTLERY.—Cutlers are complaining of a deficiency of orders for the poorer descriptions of cutlery. The better qualities, which bear a less import duty on entry into foreign ports, are selling fairly well.

THE ETHICS OF INDUSTRY.—A lecture, entitled "The Ethics of Industry," which was read before the St. Andrew's Literary Society by Mr. C. A. Kirby, and which deals with the evils of unrestricted competition in trade, has just been reprinted. In this lecture the author says that "competition has in its day been a power for good in the way of incentive to exertion and discovery," but that "if still useful within certain limits, competition may at present be largely overdone." The author traces the history of the profit sharing system, and advocates its extended adoption as a means of improving the present condition of workers.

NORTH STAFFORDSHIRE, 10TH JUNE, 1891.

THE IRON TRADE.—There is no improvement in respect of either prices or demand. The collapse in the Scotch market was quite anticipated, and cannot be said to have exercised any influence on the course of local markets. Bars are being sold at prices ranging from £5 12s. 6d. to £5 15s. per ton, and pig iron from 38s. for cinder iron to 42s. 6d. for forge qualities. It is rumoured that there is to be a further restriction in the output of the crude metal through one or more blast furnaces being blown out. Most of the forges are only working four days per week, and some are at a standstill altogether. Under the sliding scale ironworkers' wages underwent a reduction of 2½ per cent. last week.

THE COAL TRADE.—As is usual at this time of the year the demand for house coal shows signs of falling off, and prices are weaker. The supply of manufacturing fuel is largely in excess of the demand, and general reductions are being conceded to induce business, though there has been no corresponding alteration in the cost of production.

CARDIFF, 10TH JUNE, 1891.

IRON AND STEEL.—The condition of the steel trade is unaltered. Makers are well supplied with orders for Bessemer bars for tinplate works, but as the stoppage of nearly all the tinplate establishments in July has now been definitely determined upon, there is not much prospect for bar makers after this month. There is a better inquiry for steel rails, principally for small parcels in light sections. Heavy sections are quoted at £4 10s. to £4 12s. 6d. Rubio ore second-class quality has been sold at 12s. 3d. to 12s. 6d. per ton c.i.f. Cardiff and Newport, but for best sellers are firm at 12s. 9d. to 13s. Several cargoes of African ore have arrived this week.

COAL AND COKE.—The steam coal market is not quite so active this week. Colliery owners are well supplied with orders up to the latter part of the year. The question of additional dock accommodation is being much discussed, and the suggested scheme for forming a Harbour Trust to assume control of the Bute and Penarth Docks and provide an additional dock on the West Mud is finding general favour. Steam coal is quoted at:—No. 1 quality 15s. 3d. to 15s. 6d.; No. 2 quality, 14s. to 14s. 9d.; No. 3 quality, 13s. 3d. to 13s. 9d.; No. 4 quality, 12s. 9d. to 13s. Household sorts are weak. Coke is in limited demand, prices for furnace being 19s. to 19s. 6d.; foundry, 21s. 6d. to 22s. 6d.; special foundry, 24s. to 25s.

A NEW OIL DISTRIBUTOR FOR SHIPS.—An oil distributor has been brought out by Captain C. C. Conves, of Penarth, and tried with satisfactory results on the s.s. "Arrow." The new invention distributes oil in a perfectly even and continuous flow from the bows of the vessel. It consists of a circular tank or reservoir above a cylinder, and this is fixed in the fore-peak of the ship, as near the bow as possible, and at such a height as to be a little above the waterline when the cargo is on board. Two small copper pipes run from the lower part of the cylinder out through the bows (one on each side), and by means of brass cocks the oil in the cylinder is allowed to run out just over the broken water caused by the passage of the vessel. The pipes at their outlets are not above $\frac{1}{16}$in. in diameter, so that the quantity of oil they allow to run out is small, though quite sufficient to subdue the heaviest seas. A strong steel piston works on a spindle rod through the cylinder, and forces the oil through the pipes when the cocks are open, so that the jets flow several feet out beyond the bows, and prevent the water coming inboard. The cocks are quite separate, and will allow of the oil being distributed on one side only if need be. The reservoir will hold about seven gallons of oil, and the cylinder about five, which will last some four hours with the two jets full on. Seal oil has been tried with the best results, but other kinds of crude oil can be used at pleasure.

BARROW-IN-FURNESS, 10TH JUNE, 1891.

HEMATITE.—The collapse of the "ring" in warrants has led to the entire suspension of business during the week, with the result that stocks remain steady at exactly the same amount as the previous week—viz., 139,543 tons. The demand on both home and foreign account is comparatively small. Warrants have been reduced in price to 48s. per ton net cash, and Bessemer qualities are quoted at 50s. per ton net f.o.b. Forty-one furnaces are now blowing, compared with forty-five in the corresponding week of last year, and there are thirty-six furnaces standing idle.

STEEL.—The steel trade is quiet, and orders are not plentiful either in the Bessemer or the Siemens-Martin departments. At Barrow the works have orders in hand which will keep them employed for the remainder of the year, but in West Cumberland two of the large works have very few orders, while the only other works of any importance have not enough contracts to enable them to keep their mills fully employed. Heavy rails are at £4 11s. 6d., light rails at £5 15s., and colliery rails at £6 15s. per ton. Steel ship plates are in quiet demand at £6 2s. 6d. per ton, angles at £5 10s., and steel boiler plates £6 15s. per ton.

SHIPMENTS.—The shipping trade shows a slight improvement. The exports of pig iron and steel for the past week amounted to 25,467 tons, compared with 18,702 tons in the corresponding week of last year. The shipments to date this year represent 437,528 tons, against 474,565 tons in the corresponding period of last year, a decrease of 37,037 tons.

MIDDLESBROUGH, 10TH JUNE, 1891.

PIG IRON.—The tone of the iron market was more cheerful yesterday than it has been for some time past, though very little business was done. During the last few days of last week prices fell rapidly, brought about by the decline in the value of Scotch warrants, until on the 5th inst. Cleveland warrants were quoted at 39s. 1½d., and on the 8th inst. at 39s. Some sellers would even accept 38s. 9d. Yesterday, however, prices recovered a little, and Middlesbrough warrants were advanced to 40s. cash sellers, and 39s. 9d. cash buyers. Merchants quoted 39s. 6d. for prompt f.o.b. deliveries of No. 3 G.M.B., and 39s. 3d. would readily be paid. Some business has been done in grey forge at 37s. 6d. per ton, but 37s. 9d. is about as little as will be taken. Mixed numbers of local hematite can be bought at 51s. per ton. The stock of pig iron in Connal's stores continues to increase, and up to the 8th inst. there were 128,219 tons, an increase of 2,650 tons for this month.

IRON AND STEEL.—In the finished iron and steel trades there is no improvement, and work is slack at most of the mills and forges. Quotations are, however, maintained, and are as follow:—Common bars, £5 12s. 6d.; best bars £6 2s. 6d.; iron ship plates, £5 10s.; steel ship plates, £6; iron angles, £5 5s.; steel angles, £5 15s., all less 2½ per cent. for cash on the 10th of the month and f.o.t.—In the annual report of the Darlington Iron and Steel Company, recently issued, the directors recommend a dividend of 7 per cent. on preference shares and of 4s. per share on ordinary shares. Last year no dividend was paid on ordinary shares. Messrs. Bolckow, Vaughan, & Co. have secured an order for 5,000 tons of those small pigs known as "copper catches" from a Spanish firm.

SHIPMENTS.—The shipments of pig iron from this port continue to be satisfactory, and amounted to 23,950 tons up to the 8th, as against 23,795 tons for the corresponding period of last month. Of the 23,980 tons, Scotland took 12,710 tons, England and Wales 2,615 tons, and 8,625 tons went to foreign ports.

NEW HARBOUR NEAR MIDDLESBROUGH.—For some two or three years past the Skinningrove Iron Company has been constructing a harbour in the bay close to the works, which are situate on the Yorkshire coast, about twenty miles east of Middlesbrough. At present they have to send any iron they may have to ship up to Middlesbrough at considerable cost, but this harbour will enable the company to ship direct, besides which it can get supplies of fuel by sea. The work is now nearly completed, and the company expects to be loading vessels early next month.

SUNDERLAND, 10TH JUNE, 1891.

THE SHIPPING AND COAL TRADES.—There is no improvement in the condition of these trades. The freight market continues to be depressed. During last week 68,399 tons of coal were shipped at this port, an increase of 2,458 tons over the previous week. 33,769 tons went coastwise, and 34,630 tons to foreign ports, as well as 300 tons of coke, 400 tons of patent fuel, and 30 tons of firebricks. There was also shipped coastwise 250 tons of patent fuel, 180 tons of coal tar, 180 tons of steel plates, 130 loads of timber, 5,000 dozen glass bottles, 25 tons of cement, and two cargoes of miscellaneous goods.

IMPORTANT HARBOUR WORKS.—Recently Sir John Coode made a careful examination of the entrance to the River Wear and the new pier at Roker, now under construction, and considered three sites for the proposed new South Pier. He reported to the River Wear Commissioners in favour of the proposal of Mr. H. H. Wake, engineer to the River Wear Commissioners. It was decided to adopt Sir John Coode's recommendation, and to proceed at once with constructing about one-half the length of the new pier, which is to be 2,870ft. in length, and is to cost about £100,000.

NEWCASTLE, 10TH JUNE, 1891.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock during the week ending the 6th inst. amounted to 113,571 tons, being a decrease as compared with the corresponding week last year of 5,704 tons.

ENGINEERS AND PLUMBERS.—The dispute between these sections of operatives, which for some weeks past has put a stop to work in the engineering department of Messrs. Palmer's establishment, Jarrow, has now caused the work on four vessels in course of construction to be suspended, and the Howden Yard, belonging to the firm, has been temporarily closed. At other engineering works on the river notices to terminate engagements have been served on the fitters and other workmen; and this action of the employers is attributed to their desire to put an end to the unseemly conflict at Jarrow. The plumbers have signified their willingness to have the dispute referred to arbitration, but the engineers object to that mode of settlement. The engineers are consequently responsible for the present deadlock, which, if it continues for any considerable length of time, is bound to bring about most calamitous results.

SHIPBUILDING.—The signs of coming slackness are becoming more noticeable at many of the shipbuilding establishments, and, though one or two of the largest yards still maintain an appearance of briskness, it is clear that the quantity of prospective work is limited. Several vessels have been launched lately, and the berths they occupied still remain vacant. During the present year scarcely any orders have been received, and any new work that has been begun was simply the outcome of negotiations completed in the summer or autumn of last year. A reduction of wages will doubtless be asked for shortly.

CEMENT WORKS.—There is just now a good demand for Portland cement, both for local use and for exportation, and the whole of the works in the district are kept briskly employed. Messrs. Wailes, Dove, & Co., of St. Nicholas Buildings, are very busy with the manufacture of their marine cement for ships' bilges.

CHEMICAL AND COPPER WORKERS' UNION.—The first annual report of the Chemical and Copper Workers' Union, which has just been issued, states that many advantages have been obtained by chemical and copper workers through their connection with the Union. Wages have been increased, and hours of work have been reduced. It is not stated how far the increased cost of production has made these manufactures unremunerative. Regret is expressed in the report that the chemical and copper workers are not represented on the Labour Commission.

ASSOCIATION OF STUDENTS INST.C.E. — Under the auspices of the Newcastle-upon-Tyne Association of Students of the Institution of Civil Engineers, an excursion to the Manchester Ship Canal has been arranged to take place on the 26th and 27th inst.

THE S.S. "MARIA."—This vessel, which was launched on the 23rd ult., has been electrically lighted by Messrs. Ernest Scott & Mountain, Ld. The installation consists of a Tyne combined engine and dynamo, and 66 lamps of 16 c.p. each.

THE TIMBER TRADE.—Nineteen cargoes of timber from North Sea ports arrived in Tyne Dock a few days ago, a fact which shows that the import season has now fairly commenced. The timber being chiefly for mining purposes, will find a ready market, and much of it is already consigned to collieries in various parts of the county of Durham. In the saw mills business is moderately good, and at most of the timber yards stocks, which, after the spring sales, had become much reduced, are already beginning to be replenished.

THE BATH AND WEST OF ENGLAND AGRICULTURAL SHOW.

THIS show was opened at Bath on Wednesday, the 3rd inst., and closed on Monday last. As our readers are aware, it is for the most part a reproduction on a smaller scale of the Royal Agricultural Show, not merely in general character—this must necessarily be the case—but in the details of exhibitors and exhibits. With few exceptions, therefore, there was in the machinery and implement department nothing that calls for special notice. Most of the leading firms of agricultural engineers were represented, and exhibited the usual display of portable and traction engines, ploughs, horserakes, turnip and chaff cutters, &c., of the types with which we have now become familiar.

As usual, a considerable number of gas engines were exhibited, and among these was one by Messrs. Crossley Bros., provided with one of their new self-starting appliances, which, we believe, has not been previously shown at any public exhibition. The arrangement is extremely simple, and is said to answer perfectly. When the crank is in its mid-position on the forward stroke, and the piston consequently about half stroke—the space behind it being filled with air only at atmospheric pressure—gas is admitted by an auxiliary pipe and opening, entirely independent of the usual gas admission valve. A branch from this auxiliary pipe supplies a small horizontal gas jet which is lighted previously to starting and projects its flame over a short vertical mouthpiece or chimney communicating with the interior of the cylinder. The mixture of air and gas issuing from the chimney is ignited by the jet, and as soon as the flame assumes the blue colour indicating an explosive mixture, the igniting jet is shut off and an explosion immediately follows, which starts the engine. A "Weatherhogg" paraffin engine, similar in general construction to the benzoline engine by the same maker, first exhibited at Windsor in 1889, was to be seen at work at the Bath Show. The design, however, has been considerably improved, and whereas the engine shown at Windsor was intended for use with benzoline only, that at Bath was actuated by ordinary paraffin. The latter, too, was of the fixed horizontal type, while the former was arranged on wheels as a portable machine.

Among minor apparatus, not having any very intimate connection with agricultural pursuits, we noticed a plate and dish washing machine by Messrs. Crees & Co., of Warminster, Wilts. Under ordinary circumstances this is intended to be driven by hand, but the sample on view at the Bath Show was worked by a small electric "Whitehall" motor, manufactured by Messrs. Easton & Anderson.

At the Royal Agricultural Show last year, Messrs. Hornsby & Sons showed, for the first time, a rotary divider for reaping machines, but which, for one reason or another, was not actually attached to a machine; at the Bath Show such a divider was exhibited as an integral portion of one of the firm's reapers. It is stated to be more effective than the ordinary divider, especially for heavy and tangled crops.

Locally—in Bath and the surrounding agricultural district—very great interest appeared to be excited by the show, which was well attended. In connection with dairy appliances, a gold medal was offered for the best means of determining the amount of butter fat in milk, and a second gold medal for the best method of testing the acidity in milk. There were two competitors—the same firms—for each prize, but the judges recommended that the medals should not be awarded.

HIGHER SPEED ON INDIAN RAILWAYS.

THE demand for higher speed on Indian railways has been met hitherto by the convincing arguments that the lines are mostly unsuitable for fast travelling, and that it would not pay to run fast trains. As regards the latter contention, it is sufficient to say that public opinion has virtually compelled the East Indian Railway to expedite their mail trains, and the tendency is for other lines to follow suit. The unsuitability of railways in India for fast speed is, states *Indian Engineering*, a myth. It has been absolutely proved that trains travel smoother when going at considerable speed than they do if the pace is slow. The main directions in which improvement in travelling in India may be effected are in increased speed of mail trains and in better carriages. In England and on the Continent a very noticeable change for the better in the carriages has been effected of late years, but in India progress has been slow, and there are many desirable improvements which should be carried out.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 12TH JUNE, 1891.

SAFETY IN OCEAN TRAVELLING.

AT the present time, when we hear so much about swift ocean travelling, and when proposals are being made to still further increase the speed of steamers, it is well to consider the question from the side of safety, so that the public may form some idea of the probability of increased danger, which is usually supposed to accompany increased speed. Few persons would be inclined to shorten an ocean voyage if they ran a great risk of suddenly ending their days by so doing. Therefore a glance at the past history of the subject may be interesting. From the time of the inauguration of Atlantic Ocean transit in 1838, until 1879, 144 steamers of all classes were lost in that trade. Some of these, however, were not very important. The first which was lost was the "President," which disappeared mysteriously in 1841. It is a somewhat noteworthy fact that during the next thirteen years only one life was lost through the loss of an Atlantic steamer, and that was in the "Columbia," of the Cunard Line, which went ashore in 1843. From 1854 the losses became very frequent, and are probably to be accounted for by the change which was being made from sailing vessels to steamers, and the want of experience, not only of the officers in charge, but also of the shipbuilders and engineers who were responsible for the construction of the ships and engines. In 1854 the steamship "City of Glasgow," with about 480 persons on board, disappeared, leaving no trace behind, and in the same year the "Arctic," of the Collins Line, and one of the fastest steamers then afloat, was sunk in a collision off Cape Race, and 562 persons perished. Two years later the "Pacific," of the same line, disappeared, leaving no trace behind. A remarkable fact in the history of the Allan Line is that, between 1857 and 1864, it lost no fewer than nine steamers. The Hamburg-American steamer "Austria" was, in 1858, burned at sea, with a loss of 471 lives. Of the more remarkable losses since that date may be mentioned the Inman liner, "the "City of Boston," in 1870, the White Star liner "Atlantic," the German steamer "Schiller," the North German Lloyd steamer "Deutschland," the Hamburg-American steamer "Pomerania," and the French steamer "Ville du Havre." When we analyse the causes of the losses up to 1879 we find that twenty-four vessels never reached the ports for which they sailed, their fate being veiled in mystery, ten were burned at sea, eight were sunk in collisions, and three were sunk by ice. Since 1879 it is satisfactory to find that the number of losses have not been nearly so numerous. The most memorable are the burning at sea of the "Egypt," of the National Line, and the "City of Montreal," of the Inman Line, both without loss of life; the stranding of the "State of Virginia," and the sinking of the "State of Florida," by collision with a sailing ship, and of the "Oregon," in collision with a coal schooner. These facts are so far satisfactory that they show a great decrease in the list of accidents during what may be considered the modern period of the steamship. This may be accounted for by the fact that, having passed the transition period, the officers in charge were more thoroughly acquainted with their duties, and the ships and engines were more efficiently constructed. The record of last year is of a most satisfactory kind. Notwithstanding all the risks from collisions, hurricanes, icebergs, and other causes, we find that nearly 2,000 trips were made from New York alone to various European ports, and that about 200,000 cabin passengers were carried, in addition to 372,000 immigrants, all without any accident. The risk of collision has been very much reduced by the adoption of the system of "steam lanes," suggested by Professor M. F. Maury—that is, of having definite courses for the steamers, based on calculations as to probable areas of fog and ice. If any accident should occur to a steamer there is thus every probability that assistance will be rendered by one of her companion ships.

The improvements which have taken place in the methods and appliances of navigation have, no doubt, added much to the safety of the ships, and this has been increased also by the higher standard of education, and consequently of intelligence, than formerly was found, both among officers and men. Sir William Thomson, in a volume of papers recently published, has said: "It is a common saying that sailors are stupid; but I thoroughly and heartily repudiate this statement, not from any sentimental fancy, but from practical experience. No other class of artisan is more intelligent; and, moreover, sailors' wits are kept sharp by the ever nearness of difficulties and dangers to be met by ready and quick action." Sir William himself has done much to improve navigation, not only by his writings on subjects directly connected with it, but also by his inventions. His improved compass and his sounding apparatus are to be found in all first-class steamers, and his influence has been felt in many direct and indirect ways. We would refer to the volume of papers above mentioned on subjects relating to navigation for full details regarding these, and also for suggestions which may come to be of great practical utility in the future. He expresses the opinion that the regulations for preventing collisions at sea contain everything that human wisdom has been able to devise for diminishing the chances of collision. The action of the recent Maritime Conference at Washington showed that the members agreed with this opinion, as they proved very conservative in their policy. They declined to adopt a large number of resolutions sent in from more than one country of importance, and contented themselves with a number of not very important amendments, and with the passing of some new rules for the marking of wrecks and the removal or destruction of derelicts. Considerable improvements have been made in recent years in lighthouse arrangements, but Sir William Thomson would like to see all the lighthouses flashing out their characters like electric signals, instead of the present rather slow revolving method. A certain advance has been made in another direction in the application of the Morse alphabet to marine signalling by sounds. Sir William is anxious that lighthouses should be able to flash light signals. He says that a lighthouse, to fulfil the reason of its existence, must not only be seen, it must be recognised when seen. He argues that there has not hitherto been amongst lighthouse authorities quite enough determination to make every effort to give a distinctive character to coast lights which science and common sense have placed at their disposal. The dangers from collisions with

Digitized by Google

icebergs have been reduced by the useful charts which are issued by the Hydrographic Bureau at Washington. From the records of this Office it appears that from 1882 to 1890 thirty-six steamers were more or less injured by ice in the North Atlantic, although some of these were freighting and coasting vessels. Probably the commonest explanation of the fate of missing ships is collision with ice in fog or in the darkness of the night. In case of accident, the number of boats now available is much larger than formerly, but to ensure that all the passengers in one of the large Atlantic steamers should be accommodated would require a very great amount of space.

We need not go into details of the improvements which have taken place in the construction of the ships and engines, as we have drawn attention to them from time to time. A large number of bulkheads is the most important point which requires attention in order that safety may be ensured, and, in fact, these and double bottoms are prime necessities. The bulkheads should not only be transverse, but also longitudinal, so that the engines driving separate screws may be quite self-contained. There can be no doubt that the bulkheads saved the "City of Paris" last year, and that was the case in spite of the fact that the longitudinal one was damaged by the breakage of the engines. It seems rather odd that the twin-screw and separate engines did not commend themselves to shipowners and shipbuilders at an earlier period, as they had been in common use in the Royal Navy. Of course in the Navy the arrangement was adopted on account of its advantage in manœuvring, but the security afforded by it in case of accident to one set of the engines is a sufficient reason for its being adopted in large passenger steamers. This has already been recognised by the proprietors of some of the most influential lines. The improvement in the quality of the materials used in the construction of ships and engines, as well as in the methods of working them, has done much to lessen danger, and we are convinced that our shipbuilders and naval engineers are now in a position to take a considerable step in advance as regards speed without lessening the safety of ocean travelling.

PROGRESS IN INDIA.

The great problem in India, which has been confided to the people of this country to solve, is one which deserves more attention than it receives from our politicians and legislators, as it is one of great complexity, and on its right solution will depend, not only the welfare of millions of our Eastern fellow-subjects, but also to a very considerable extent the continued prosperity of many of the industries of this country. The statement which is laid every year before the House of Commons, exhibiting the moral and material progress and condition of India, may, in a sense, be regarded as an elaborate balance-sheet, showing from year to year the measure of success which is attending our rule in the East, and the numerous problems—political, economic, industrial, and financial—that are constantly calling for solution. It affords a great deal of material, not only for study, but also for discussion, if only sufficient interest could be excited in it. While we do not think it desirable that the House of Commons should be made a court of review of the doings of the Government of India, we think it a misfortune that greater interest is not taken in our great dependency.

Possibly one of the most important movements, and the one which is likely to have most effect on the future of India, is the development which is taking place in local government. No fewer than 755 towns in British India have been formed into municipalities, and, besides these, many district and local boards have extensive powers of various kinds. In these and other ways the people of India are learning practically how to govern themselves. Of course, difficulties and differences of opinions occur, but with regard to the main objects on which municipal funds are spent—namely, water supply, hospitals and dispensaries, streets and roads, drainage, sanitation, and education—the general opinion seems to be that municipalities do more for the benefit of their citizens than was done before by Government officers. In the matter of water supply and sanitation considerable progress has been made, but, of course, a great deal still requires to be done. When we consider that during the past ten years the population has increased by 29 millions, and that it now reaches a total of 286 millions, we have some idea, not only of the magnitude, but also of the rapidly increasing complexity, of the problem, and that, in the matter of education especially, the development has not kept up with the increase of population. The sea-borne trade of British India increased during the year by a hundred million rupees. From an industrial point of view, possibly the most important fact is that the imports of cotton goods declined 4 per cent., and metals and machinery increased 24 per cent., both facts being indicative of the industrial development which is taking place in India. Machines and the materials for making them are being imported, while the factories are beginning to turn out textile and other products sufficient for the wants of the people. The output from Indian coal mines during 1889–90 was upwards of two million tons of coal, or 19 per cent. more than in the previous year. The intellectual activity of the country was represented during the year by 9,725 new books and publications, including, however, new editions of old works, and of these about nine-tenths were in the vernacular languages. On the whole, the statement of progress in India is one which we can contemplate with considerable satisfaction.

CORNELL UNIVERSITY.

In keeping our readers informed of the educational progress of the world, we have very often found it necessary to refer to institutions in the United States of America as illustrations of the arrangements which are necessary in order that the educational wants of the times may be supplied, for, notwithstanding the progress which has been made in this country, it cannot be denied that more original ventures are made in America than here. Of all the institutions to which we have from time to time referred, no one fulfils the ideal of a modern university better than Cornell University, the managers of which have steadily kept in mind the wish of Ezra Cornell to found an institution where any person can find instruction in any study. It not only has faculties in the older departments of learning, but its scientific side is practically a technical school, in which instruction can be obtained in all the modern scientific professions. We have at different times given an account of the constitution and development of the University, so that we need not now repeat details. We wish, however, to direct the attention of those of our readers who are specially interested in the subject of education, to an illustrated description of the University, which has been written by Frank C. Perkins, Associate Member of the American Institute of Electrical Engineers, and published at the Art Printing Works of Mathews, Northrup, & Co., Buffalo, N.Y., and which gives a pictorial and descriptive view of the opportunities offered by Cornell University for general and technical education. The general courses include those leading to degrees in arts, philosophy, letters, and science, and for these the facilities offered are very complete indeed. But it is to the technical courses that we wish specially to allude. These include agriculture, architecture, chemistry, civil engineering, electrical engineering, mechanical engineering, and law. In 1890–91 the corps of instruction contains the names of one hundred and seven professors and instructors, besides twenty-five special lecturers. The number of students enrolled during the same year is 1,382, of whom more than a hundred are pursuing graduate courses. We are especially interested in the Sibley College of Mechanical Engineering and the Mechanic Arts, of which Professor R. H. Thurston is the director, and in which there are twelve other professors and instructors. It includes all the necessary lecture and class rooms, extensive drawing rooms, workshops of equal extent, a mechanical laboratory for the prosecution of engineering investigations and scientific research, and for the instruction of graduate and professional engineers, as well as for the somewhat extensive course of instruction in methods of experimental work provided for undergraduates.

COOPER'S HILL COLLEGE.

A report has been in circulation that it had been decided to close the Indian Engineering College at Cooper's Hill, but we are officially informed that there is no truth in the report, and that, on the contrary, its class accommodation is at present being enlarged.

Ever since its institution by the Duke of Argyll, the College at Cooper's Hill has been the subject of considerable controversy and discussion. The Institution of Civil Engineers protested against its being started, because it was of opinion that it was desirable to have in the Indian engineering service men with different kinds of training, and therefore, to a certain extent, with different types of mind. It was pointed out that "in the proposed College the minds of the pupils will all be moulded in the same forms. There will be none of the emulation of different schools of thought and action, and none of that independence and originality of resource which have produced the best engineers."

The immediate cause of the foundation of the College was the difficulty of obtaining properly qualified candidates for the Indian engineering service under the system of open competition. It was found that the best of the young men in the profession would not come forward, and that those who did were for the most part merely crammed for the examination, and were not *bonâ-fide* engineers. The provision for experience in office and practical work was very often got in a very perfunctory manner, and was more formal than real, some men actually keeping their offices, not for executing actual works, but for the purpose of scheming proposals or making imaginary designs, so that their pupils might obtain a qualifying certificate. Since the College was instituted, however, there has been a great advance in all departments of engineering education, and there would not now be the slightest difficulty in obtaining a sufficient number of men who had passed through a college course of study and at the same time possessed a good acquaintance with practical work. There can be no doubt that, if the conditions of service in India were somewhat modified in the manner in which we have at different times indicated, there would not be the slightest difficulty in keeping the Public Works Department well supplied with thoroughly qualified men. There is only one department for which provision would have to be made, and that is forestry, for the study of which as yet no proper facilities exist in this country. But now that the Agricultural Department is taking up the subject of agricultural education, this could easily be arranged, as a slight addition to the subjects of some of the colleges would give all that is wanted—at least, all that can be done in this country, where there are few forests. At present the students of Cooper's Hill College have to spend some time in France and Germany in the forestry departments there, and this could still be done by those who were selected for India.

THE PETROLEUM WEALTH OF RUSSIA.

In view of the great interest which is attached to the development of the use of liquid fuel, we give a few details of an article which recently appeared, on the petroleum wealth of Russia, in the *Economiste Russe*. The extraction of naphtha is confined almost exclusively to the Caucasus, in the peninsula of Apchéron, and principally in the environs of Baku. After the annexation of Baku to Russia the petroleum industry was at first a monopoly, which brought into the treasury, from 1821 to 1872, an annual revenue of 87,000 roubles. This monopoly was suppressed in 1872, and an excise duty imposed, the yield of which to the Imperial Exchequer in 1888 was nearly 7,000,000, and in 1889 over 9,000,000 roubles. From 1832 to 1862 the production was confined within narrow limits, and it varied from 255,500 poods to 358,300 poods annually, the pood being equivalent to 36lb. avoirdupois. From 1863 to 1868 it rose to between 538,900 and 998,900 poods, and continued to rise until it amounted to 1,685,229 poods in 1869, the year from which its enormous development dates. In 1870 the production amounted to 1,704,465 poods, in 1875 to 6,285,728, in 1880 to 20,736,949, in 1885 to 115,000,000, and in 1889 to 206,897,100 poods, of which the environs of Baku supplied about 99 per cent.

The principal companies engaged in the extraction of petroleum are the Nobel, Caspian, Baku, Caspian and Black Sea, with other smaller companies in the neighbouring districts. The petroleum extracted from the wells is carried by pipes to the large stations or reservoirs, and thence distributed in the same manner to the works. The system was inaugurated in 1877. The distilleries are, for the most part, established at Baku, where they form a special district, which is known as the "black town." In 1889 the number of distilleries was 147, and their total product amounted to 181,590,232 poods, of which 62,000,000 were light oils, 1,000,000 heavy oils, and 113,000,000 residues. The working of petroleum at Baku is placed under the direction of a committee of experts, established in 1886. The greater part of the petroleum extracted is consumed in the interior of the empire. It is carried from Baku by the Caspian Sea, then by the Volga to Tsaritsyne, from which place a certain amount goes up the river, but the greater part is carried by rail, in tank waggons, to all parts of European Russia.

Petroleum intended for foreign markets is shipped chiefly from the port of Batoum, and the amount exported continues to grow rapidly. In 1883, refined

Digitized by Google

petroleum only represented 41 per cent. of the total exports: whereas in 1890 it was 84 per cent. In the year 1889, over 6,000,000 poods of lighting oils and benzene were exported from Russia to the United Kingdom, 4,000,000 to Austria, 3,000,000 to Germany, 2,000,000 to Italy, 2,000,000 to Belgium, and smaller quantities to Holland, Roumania, Spain, Denmark, Sweden, Norway, Greece, France, &c. Turkey took in the same year 7,000,000 poods, Persia 336,000, and Japan 330,000 poods of lighting oils and benzene. In 1888, 77 per cent. of the total exports were effected *viâ* Batoum, and in 1889, 80 per cent. The article concludes by quoting the opinion of Professor Mendeleef to the effect that there is no indication of an approaching failure of the petroleum supply of the Baku basin, leaving out of the question the other districts of Russia which still await the development of their naphtha wealth.

THE RECENT CENSUS AND LARGE TOWNS.

Some interesting results of the recent census as regards the twenty-eight large towns which are dealt with in the Registrar-General's weekly returns have recently been published. According to these returns the population of the twenty-eight towns amounted to 9,398,000, which shows an increase of about 1,000,000 over the population in 1881, or at the rate of about 12 per cent. The rate of increase during 1881 to 1891 has therefore diminished in comparison with the period 1871 to 1881, when it was computed to be 16½ per cent. It has been observed that when the growth of the population has reached a certain stage, the rate of increase has a tendency to diminish, but the large increase in the number of emigrants during the last decade as compared with the preceding decade must be considered as helping to prevent the apparent rate of increase of population from being maintained.

It was recommended by a departmental committee, which was appointed in February, 1890, that a quinquennial census of a limited scope should be taken midway between the full decennial censuses, in order that more accurate statistics may be available between those dates. The statistics recently obtained show that the population of the twenty-eight towns is less by 64 per cent. than had been estimated by a comparison of the returns of the births and deaths during the intervals. The following table shows with respect to some of the more important of the twenty-eight towns the population according to the census of 1891, the population according to the census of 1881, and the increase during the decade 1881 to 1891:—

Towns.	Population. Census 1891.	Population. Census 1881.	Increase or Decrease. 1881-91.
London	4,221,452	3,816,483	+404,969
Bristol	222,049	206,874	+ 15,175
Birmingham ...	429,906	400,744	+ 29,162
Nottingham ...	212,662	186,575	+ 26,087
Liverpool	517,116	552,508	− 35,392
Manchester ...	506,409	341,414	+164,995
Salford	198,717	176,235	+ 22,482
Bradford	210,938	183,032	+ 27,906
Leeds	369,099	309,119	+ 59,980
Sheffield	325,304	284,508	+ 40,796
Hull	184,267	154,240	+ 30,027
Newcastle	187,502	145,359	+ 42,143
Cardiff	130,283	82,761	+ 47,522

The growth of the population of London within the registration district is thus shown to be at the rate of 10 per cent. Liverpool is the second city in England as regards population, and Manchester is third, with 506,409 inhabitants, which shows an increase of 48 per cent. over the previous census. The large increase in Manchester is largely attributable to the greater area included in the last census. Glasgow is stated to have a population of 532,282. Cardiff has increased at the rate of 57 per cent.; Newcastle, at the rate of 29 per cent.; Leeds, 19 per cent.; Oldham, 19 per cent.; Hull, 19 per cent.; Huddersfield, 17 per cent.; Blackburn, 16 per cent.; and Derby, 16 per cent.

Letters to the Editor.

ARTILLERY STEEL.

To the Editor of "Industries."

Sir,—The interesting paper contributed to the Iron and Steel Institute by the Director of Ordnance, a portion of which appears in your issue of last week, is evidence that in future the character of the material of our artillery will receive the scrutinising attention that its supreme importance commands.

Without referring to the part of the contribution that describes the more or less hypothetical—shall I say fanciful?—phenomenon, I should like to make a few comments on the assertion made by Dr. Anderson, that, "like ice and water, steel and cast iron have a greater volume in the solid than in a liquid state." My experience and theoretic investigations tend to show quite the contrary, and that, like most, if not all, metals, both iron *per se* and in its carbide form as steel expand with the addition of heat, according to well-known coefficients of measure of dilation (*vide* Fizeau, *Annuaire du Bureau des Longitudes*, 1885), until a temperature is reached that destroys the static molecular integrity, and the metal becomes fluid. Even then the volumetric dilatancy proceeds *pari passu* with the increase of temperature; consequently the liquid condition must be of greater volume than its cold one. Otherwise—and here is a question for Dr. Anderson—if the cold condition occupies a greater volume than the fluid one, would not the metal, on cooling, burst or fracture the moulds containing it?

In my contribution to the discussion on Professor Greenwood's paper, Vol. XCVIII. Minutes Inst. C.E., page 200, I attempted to enunciate by calculation the formulæ, the molecular density, or equivalent specific gravity, and degree of volumetric increase of metal (steel) heated to melting point, and inversely the volumetric reduction in cooling from the fluid to the solid condition, which may be taken to equal $\frac{-22}{6967}$ of the fluid mass.

Inversely the cold steel, of a volume x, occupies a volume y when melted thus:—

$$x + \left(\frac{x + 22}{6967}\right) = y.$$

The explanation of the fact that sometimes a piece of cast iron thrown into a bath of molten steel floats on the surface is obvious.

When a pig or ingot is run or cast on cooling from the outside inwardly, the shell or outside surfaces of the ingot cool initially to near size of the internal dimensions of the mould, the internal part of the mould or casting, on being cooled, leaves gas-enclosed cavities equivalent to $\frac{23}{6967}$ of the total mass or bulk of metal.

So that actually the pig or ingot is a compound of metal and enclosed gas cavities, and its compound density and specific gravity is very little different from that of the fluid metal; and when this cold compound metal and air is thrown into the bath of steel and becomes heated, the effect of the expanded gases is evolved, and the bubbles of escaping carbon-monoxide from the metal in process of decarbonisation sometimes forces the added metal above the surface.

Let Dr. Anderson try the experiment of throwing into a bath of *dead melted steel* a piece of iron or steel of a thoroughly dense character—a portion of a steel rail or tool steel, or a broken cast-iron pipe will do—and I think he will find it disappear below the surface and remain there until melted.

Mr. Snelus draws attention to the fact that if cold steel ingots are placed in a furnace they sometimes blow up like guns. This is not, I think, so much due to internal molecular stress as to the expansion of the enclosed gases in the cavities.

A simple thermodynamic calculation will show the enormous pressure that will be exerted by the rigidly enclosed gases; as they are compressed by the influence of the added heat this effect clearly accounts for the violent rupture.

If steel ingots are imperfectly cast, oil-hardening can only partially restore molecular equilibrium. The range of useful effect of the oil is the limit of its temperature below volatilisation point—say 600°—whereas the initially internal stress is a function of 2,500° at the temperature of solidification.

The same remarks apply to annealing, but in a less degree, as the range of useful effect may be equivalent to 1,100°. If a metal is cast in a perfect state of equilibrium it requires neither annealing nor yet oil-hardening, and no mechanical treatment will improve its general characteristics, as the density of a perfect metal is unalterable, and the specific gravity is always a true index of the physical value of the metal.

There are many other points raised in Dr. Anderson's important, instructive, and inviting communication, which are deserving of attention and might *benefit by critical analysis*.

It is, I suggest, desirable, in producing metal suitable for guns or projectiles, to so cast it that its contraction cavity co-efficient x, or $\frac{22}{6967}$, shall be reduced to the lowest practicable extent; otherwise no system of treatment—chemical, thermic, or mechanical—will restore absolute molecular contact or perfect density, and consequent neutrality and freedom from internal stress of steel or iron.

Yours, &c.,
London, 6th June, 1891. B. W. Thwaite.

THE ATLANTIC MAILS.

To the Editor of "Industries."

Sir,—Will you or some of your readers kindly tell me where I may obtain the Parliamentary paper giving the times of passage in 1890 of all the steamers carrying the above mails? You directed your readers' attention to the return a short time ago.

I have tried the General Post Office here, but they do not know anything about the paper. Therefore, if you give the information desired, you will much oblige,

Yours, &c.,
X. Y. Z.

Belfast, 5th June, 1891.

[The paper referred to is "House of Commons Returns," 116, for this year, and is entitled "American Mail Service." It may be obtained from Messrs. Eyre & Spottiswoode, East Harding Street, London, E.C. Price 1½d.—Ed. *Industries*.]

THE LONDON POLYTECHNICS.

To the Editor of "Industries."

Sir,—Your interesting leading article last week, on the London Polytechnics, directs attention to a subject which should be very carefully considered, and not be allowed to drift into conventional or official lines. I have taken a great interest in the subject of education, and especially of technical education, and I must confess that I have been very much disappointed at the spirit in which the work is taken up even by those who are most enthusiastic. They seldom distinguish between the imparting of information and the giving of a good education to the students. They also fail to recognise that a man may be well informed about many things, and yet be very imperfectly educated.

In a recent report of the National Association for the Promotion of Technical and Secondary Education the opinion was expressed that "if the present movement for technical education is to end in the mere multiplication of science and art classes, formed by incompetent teachers dependent on grants for their livelihood, it may be that the resulting evil will outweigh the good. If the Technical School of the future is to consist of an ill-assorted collection of such classes as are found by experiment to be the most 'paying' from the point of view, not of the education of the boy, but of the remuneration of the teacher, omitting all those humanising studies which are 'merely' educational and not grant earning, the cause of secondary education will not be advanced, but rather thrown back by the change. What is wanted is more elasticity in method and more intelligence in teaching, and unless these results are achieved, very little good can be done."

When recently visiting the Regent Street Polytechnic I was very much struck with the great amount and the variety of the activity about the place. I was specially pleased with the great attention paid to physical development and to recreation, for when these are not overdone—as unfortunately they too often are—they are likely to do the students more good than many of the formal subjects with which they are crammed. Professor Laurie, of Edinburgh, in one of his addresses, published some time ago, said: "Give me a man with an intelligent mind and with a moral purpose in life, honest in his resolves, honourable in his aims, and I will guarantee you in that man the best manufacturer, the best merchant, the best weaver, the best engineer, the best plumber; given the necessary amount of knowledge of business and I will guarantee you against a railway king or a shoddy millionaire." The educational articles which have appeared in your journal have always taken this view of the subject, and I hope you will keep your eye on the development of the London Polytechnics, for on the lines which these take will depend the future welfare of a large number of the youth of London, and, therefore, also the welfare of the country.

It is to be hoped that your advice will be taken, and that the Institutes will be allowed to grow gradually, and be designed so that they may be extended, for, as you point out, their nature is so different from that of any institutions which have been hitherto carried out that the whole question cannot be considered to be beyond the experimental stage, and it would be a great mistake to make them all of exactly the same type.

Yours, &c.,
London, 8th June, 1891. Teacher.

CHANGES IN IRON PRODUCED BY THERMAL TREATMENT.

To the Editor of "Industries."

Sir,—Mr. E. J. Ball's paper "On the Changes in Iron Produced by Thermal Treatment," recently read before the Iron and Steel Institute, is most interesting. It affords, I think, a plausible explanation of the discrepancies summarised by me in *Industries* of April 15th, 1887, in which stress is laid on the importance of noting the variations in temperature in the working of steel.

I therein show the connection which *must* logically exist betwixt temperature and chemical composition, suggesting that the fusion point of iron must vary in accordance with its chemical composition, whence it follows that each variety of steel must be worked at a temperature corresponding to its fusion point.

Mr. Ball has demonstrated that the changes in iron produced by thermal treatment are in accordance with (as regards carbon) its chemical composition. Steel containing $\frac{1}{10}$th carbon, reaches its maximum tensile strength, when hardened, at about 1,300°. This temperature once exceeded, the tenacity of the metal diminishes, although the extensibility increases. With $\frac{2}{10}$th carbon the greatest tenacity is obtained at about 1,000°. Here the relation existing betwixt temperature and the quantity of carbon contained is distinctly shown; further additions of carbon also produce corresponding changes, until at last the point of maximum tenacity disappears almost entirely. It is quite probable that other elements, such as sulphur, &c., may lead to similar modifications as suggested by Mr. Ball.

Further, it is shown that a high carbon steel can be rendered brittle by being simply heated to 1,400°, the incipient fusion point of steel. I have commented on this in my letter previously referred to, in which I stated that differences in steel may be traced to variations in temperature, and that, strictly speaking, steel of a given chemical composition must be worked at a certain temperature corresponding to its composition to ensure good results. I further acknowledged that I knew of no means of ascertaining this, the critical temperature, stating only that it must be a fixed number of degrees below the melting point.

I have in my possession a steel rail which is as brittle as glass—in fact, weaker than crude iron—containing only ½ per cent. carbon, and hitherto the cause of this extreme brittleness has remained unexplained.

It is probable that the brittle rail must have been accidentally treated in a somewhat similar manner to that of Mr. Ball's sample. It is urged that the change is due to a form of iron existing only at temperatures approaching the melting point of the metal, but rendered stable at lower temperatures by hardening or by the pressure of carbon; and certainly, having regard to the recent researches of Osmond and others, this seems probable. I am of opinion, however, from certain researches, as yet very incomplete, that so-called iron contains another more volatile body, and presumably of an intermediate fusion point, betwixt iron and manganese, but I do not wish to insist upon this, as, so far, I have been unable to demonstrate its presence by isolating it from iron.

When I wrote my letter to you in 1887, I was, of course, quite ignorant of the researches of Osmond, and, in fact, I do not wish it to be inferred that my remarks constitute a claim to priority. This letter simply goes to show how practical experience, extending over a long period, seems, on the whole, to confirm the recent researches of Mr. Ball and others.

Yours, &c.,
Metallurgist.

South Wales, 9th June, 1891.

MANNESMANN TUBES FOR HIGH PRESSURE TRANSMISSION.

(From our Berlin Correspondent.)

At a recent meeting of the German Industrial Union, held in Berlin, Dr. W. Siemens gave some interesting information on the use of Mannesmann tubes for the transmission of naphtha at high pressures. Dr. Siemens owns the Kedeberg copper mines and foundries in the Lesser Caucasus, the working of which was rendered difficult by the scarcity of coal and wood. Naphtha, which exists in bulk at Baku as raw petroleum, or the distilled form of it known as "masut," has been, therefore, utilised as a substitute for coal and wood in the working of copper. It is forced into large round furnaces, constructed after the pattern of Mr. F. Siemens, by steam at high pressure in the form of spray. Sufficient heat is thus produced to melt the ore after it has been mixed with the necessary fluxes, and the copper regulus is separated, which can then be further treated in similar furnaces. The transport of the "masut" was attended with great difficulty, as the works are situated on a high plateau, which descends with steep sides to the Kur steppes. The road from the railway station to the foot of the plateau passes over a steep mountain range more than 3,300ft. high, so that mechanical transport was alone practicable. Cable railways and toothed wheel railways were projected, but the great difficulties of the ground, and the unfavourable experience of Dr. Siemens with regard to the use of cable railways, caused both these methods to be abandoned. The use of a tube was then suggested, by which the "masut" might be pumped up from the low-lying railway station. It was found that a pressure of about 1,500lb. per square inch would be necessary, and no tubes had been constructed hitherto which would bear such a working pressure except the Mannesmann seamless steel tubes. For some little time past one of these tubes has been in operation at Messrs. Siemens' works in the Caucasus. Its length at present is only 14½ miles, whilst the distance from the railway station to the works is about 28 miles. The tube at present raises the "masut" to the top of the plateau, but it is proposed to continue it as far as the works, although the transport on the plateau might be effected by other means. The pumps, which were made by Messrs. Humboldt, at Kalk, near Cologne, have been placed at the foot of the mountain, and raise the naphtha, at a pressure of 1,320lb. per square inch, from a reservoir at the station to a reservoir which has been constructed on the top of the plateau. The internal diameter of the tube is 100mm., and it is 4½mm. in thickness. Completed tubes in long sections have been tested, with a pressure of 2,250lb. per square inch, at the works of Messrs. Mannesmann, at Kommotan and Remscheid. The pump has raised hitherto 22 tons daily, but this amount might be increased considerably, since the pressure could be safely raised. There is no leakage in the pipe. Dr. Siemens stated that the erection of the installation would have been impossible except by using the Mannesmann tubes. He thinks that there would be no difficulty in constructing tubes which would bear a pressure of thousands of pounds per square inch, and that transmissions of high pressures for various purposes will henceforth come into more extensive use.

NOTES ON PATENT LAW.

V.

(Continued from page 496.)

The rule that a complete specification must describe the patented invention with such clearness as to enable a competent person, without further direction or experiment, to make the patented article or perform the patented operation, is one that has given rise to much discussion, although, in principle, it is perfectly clear. The principle, as we stated in our last article, is that the reader of the specification may be able to learn from it to practise the patentee's art or to produce his article, very much as he would have learnt if he had been bound apprentice to the patentee for the purpose. Now, this seems to imply a very high degree of precision and great fulness of detail, since otherwise a written description could hardly be supposed to be in any sense equivalent to workshop training. But the force of the principle has been somewhat broken by the rule which has obtained in courts of law that the reader who is to be so instructed is not one who brings a mind quite uninformed to the consideration of the subject, but, on the contrary, one already skilled in the art to which the specification relates. Otherwise it is plain that the rule would have run to absurdity. If every patentee were obliged to start with the elements of his subject as he would if he were beginning to instruct an apprentice in his workshop, it is plain that every specification would assume the proportions of an encyclopædia, and would be overwhelmed with practically useless matter. But if the patentee can take for granted on the part of his readers a general acquaintance with the state of knowledge and familiarity with existing practice in the trade with which he is concerned, the principle already laid down comes to no more than this:—He must with the utmost fulness and particularity specify every step which is novel in his process, and not such as workmen versed in the industry would ordinarily and customarily take. And this is, indeed, the effect of the multitudinous decisions which have been given upon this point. The late Master of the Rolls, Sir George Jessel, stated it in the year 1876, with his accustomed clearness, in the following terms:—"It is plain that the specification of a patent is not addressed to people who are ignorant of the subject matter. It is addressed to people who know something about it. But then there are various kinds of people who know something about it. If it is a mechanical invention . . . . you have, first of all, scientific mechanicians of the first class, eminent engineers; then you have scientific mechanicians of the second class, managers of great manufactories, great employers of labour, persons who have studied mechanics, not to the same extent as the first class, the scientific engineers, but still to a great extent for the purpose of conducting manufactories of complicated and unusual machines, and who, therefore, must have made the subject a matter of considerable study, and in this class I should include foremen, being men of superior intelligence, who, like their masters, would be capable of invention, and, like the scientific engineers, would be able to find out what was meant even from slight hints, and still more from imperfect descriptions, and would be able to supplement so as to succeed, even from a defective description, and, even more than that, would be able to correct an erroneous description. That is what I would say of the two first classes, which I will call the scientific classes. The other class consists of the ordinary workman, using that amount of skill and intelligence which is fairly to be expected from him—not a careless man, but a careful man, though not possessing that great scientific knowledge or power of invention which would enable him by himself, unaided, to supplement a defective description or correct an erroneous description. Now, as I understand, to be a good specification, it must be intelligible to the third class I have mentioned, and that is the result of the law."

But even with these explanations the rule will not seldom be hard to apply. The case which Sir George Jessel was discussing was a simple one, because it related to a mere mechanical invention, and mechanicians of every degree of accomplishment in the scientific and practical knowledge of mechanics are easily found and commonly known. But a very large proportion of modern patents relate to chemical processes and electrical appliances. In these cases it is often impossible really to address oneself to a reader of the standing of a workman, because the subject lies wholly out of his range. Take, for example, the numerous inventions in recent years for turning petroleum or coal tar to use for industrial purposes. These mostly depend upon reactions between complicated chemical substances, and can only be explained by means of elaborate chemical formulæ and highly technical descriptions. To imagine that a labourer or furnaceman could read such a document intelligently would be ridiculous, and, in point of fact, the witnesses who are habitually called in patent actions to speak to the sufficiency of a specification, not merely in reference to these more complicated subject matters, but even in respect of simple mechanical inventions, are persons of eminence—Fellows of the Royal Society, Presidents and ex-Presidents of the Institutions of Civil or Mechanical Engineers, of the Chemical Society, and Institution of Electrical Engineers. No doubt they are asked to say whether, in their opinion, a competent workman would understand the specification, but in answering such a question they doubtless credit the hypothetical workman, not only with a thorough practical knowledge of his craft, but also with a sufficient acquaintance with scientific literature to be able to understand its technical terms and follow its technical argument. Thus it comes to pass that in practice the law conforms to the requirements of common sense. A patentee is constrained to make a frank and full disclosure, according to the best of his knowledge and ability, of what he has patented; but he is not exposed to the risk of having his rights defeated by the mere ignorance and dulness of his neighbours. In other words, his specification will not be held to be insufficient merely because it is difficult to understand. If the difficulty is none of his making, but is inherent in his subject, it will not hurt him; but if it arises through his fault—that is to say, if he has omitted something essential to a correct statement of his meaning, or has misstated some essential point in such wise as to mislead his reader—then the specification will be held to be defective, and so defective that the patent grant is void.

There is a second reason which is given in most of the older cases for this rule that a specification must sufficiently disclose the patentee's invention—namely, that the public may know what is the prohibited ground off which they are warned. The Patent Act of 1883 has, however, made a slight difference—though but a slight one—to the rule of law in this particular. Prior to the passing of that statute it was optional with a patentee to include in his specification a distinct and formal claim, or not to do so. But now his complete specification *must* end with such a claim. It is to this that the public look when they desire to know what would be an infringement of the patentee's rights, and, as we shall be dealing later on specifically with claiming clauses, we may for the present defer the consideration of this other reason for the rule. No doubt, if a patentee intended to dispense with any formal claim, it would be necessary for him to bear in mind throughout his description that the new matter must be made sufficiently distinct from the old to afford his readers the means of telling how much of what he had described they were free to use; but if he puts in a formal claim defining his invention, it is not until that point is reached that he needs to consider its exact boundaries. For practical purposes, therefore, since all complete specifications nowadays are drafted in this way, the only object which a patentee needs to have in view in the preparation of his description is the impartation to the competent workman of what has been his own secret, and will, while the patent lasts, be his own monopoly.

In our next article we shall deal with the law relating to specifications, as apart from claiming clauses.

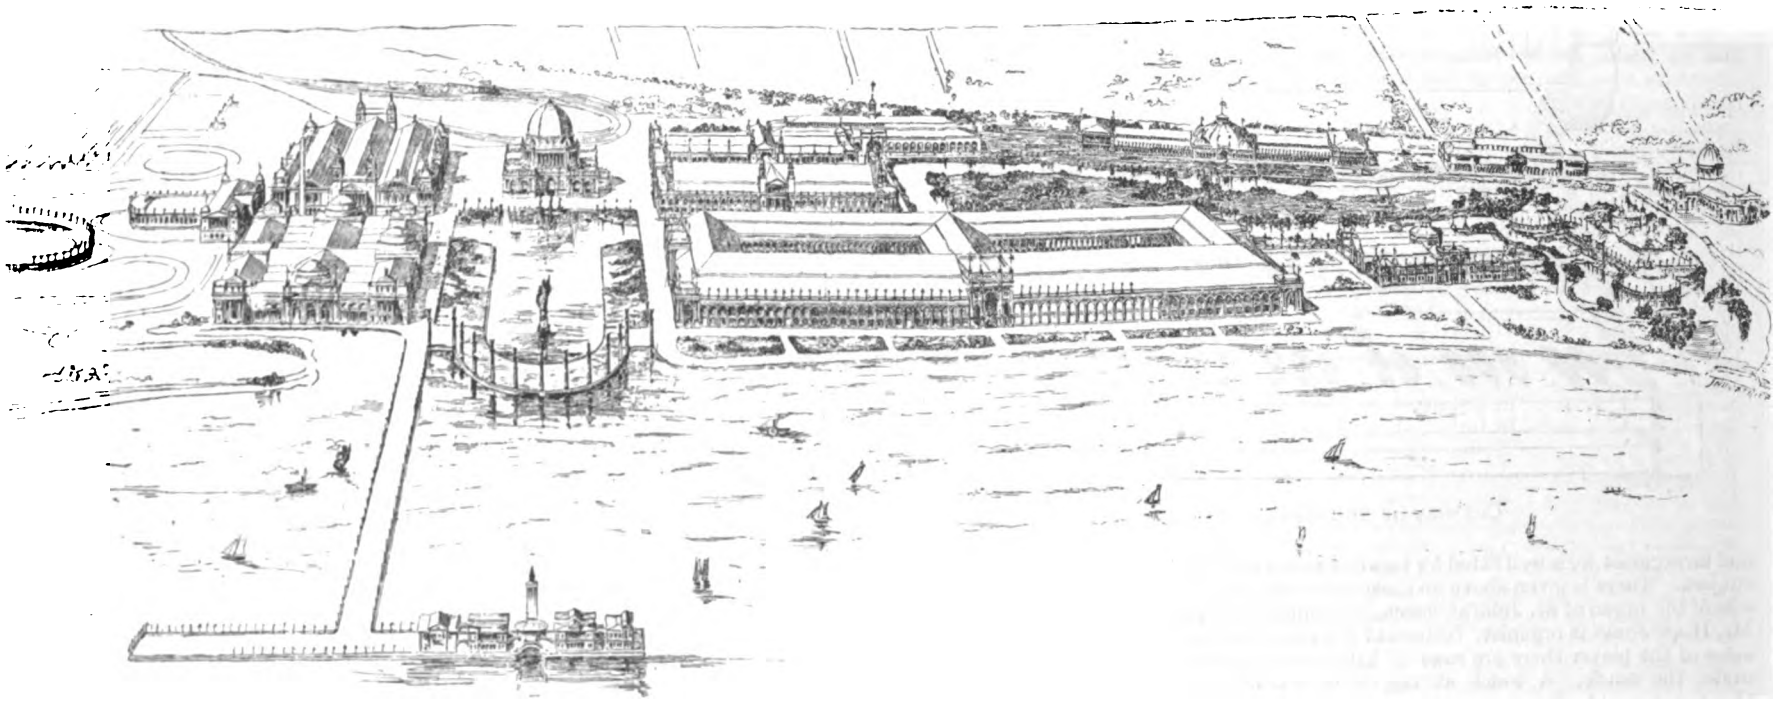
Reviews.



Text-Book on the Steam Engine. By T. M. Goodeve, M.A. London: Crosby Lockwood & Son. 1891.

A book which has reached its eleventh edition would usually be considered to be beyond the sphere of review, as the impression would be that that part of the public for which it was intended had so thoroughly approved of it that nothing more was to be said about it. When, however, we remember that Mr. Goodeve is not only Professor of Mechanics at the Normal School of Science and the Royal School of Mines, but also Examiner in Applied Mechanics and in Steam for the Department of Science and Art, we see at once that anything that proceeds from his pen is not to be estimated in the ordinary manner. Hundreds of teachers and thousands of students look upon the writings of a man holding such positions as worthy of the most careful attention, and in many cases they are carefully crammed, without much intelligent thought, far less criticism. It is therefore all the more necessary that scientific journals should attempt to estimate them quite impartially. During the past few years great improvements have taken place in the examinations of the Science and Art Department, but those who have carefully looked into the matter feel that the subjects for which Professor Goodeve examines have not made the same advance as the others, and that it is possible for students to pass fairly well who carefully cram from his text-books, and who have a very superficial knowledge of the subjects. We must confess that Professor Goodeve, and, in fact, all examiners who are also authors of text-books, occupy rather invidious positions, which tend to reduce teaching in their subjects to a dull routine of low uniformity, however good their books may be.

We may say at once that we do not make these remarks because we have a bad opinion of Professor Goodeve's book. Its contents, on the whole, are good, and students who are taught the subjects in an intelligent manner will find them very useful. The chief

THE WORLD'S FAIR AT CHICAGO.

General View of the Exhibition Buildings Looking West.

fault we have to find with it is in its arrangement, or rather, we should say, its want of arrangement, for it has increased in size, not by a process of systematic growth, but by one of addition. Bits have from time to time been added on, which, however good in themselves, were not in their proper place as regards order and arrangement. Even in the first edition we can remember that this fault was very evident. The book was not so much a systematic treatise on the steam engine as a collection of notes, rather loosely thrown together, and without much connection. Some parts seemed to enter rather fully into the the theory of the subject, but they led nowhere, their bearing on the practical parts was not shown, and the students naturally asked—What is the good of all this theory unless you apply it? Even in the more practical parts there was a curious mixture of subjects, compiled from a great many sources, one of which was easily recognised as the author's well-known text-book on "Mechanism."

We need not discuss the original part of the book, but will simply suggest that, as some sections of it are rather antiquated, they might well be re-written, and supplied with more modern examples and facts, especially relating to multi-cylinder engines. The present edition has two supplements, the first being on gas engines, and the second on the theory of heat engines. The action of gas engines is explained in a very simple and, on the whole, satisfactory manner, so far as the space allowed will admit, but it would have been much better if this had been kept apart and formed into a separate book. The present arrangement looks too much as if it were intended to meet the requirements of the examinations of the Science and Art Department, rather than the wants of students or of engineers.

The part on the theory of heat engines is very good so far as it goes, and gives some elementary demonstrations of matters which are usually proved entirely by the aid of higher mathematics, but students will ask, Why is this at the end of the book? Each paragraph may no doubt be made the subject of an examination question, but the object of a text-book on the steam engine is not to turn out smart examination machines, but intelligent engineers, who are well drilled in theory, and are able to apply it to their everyday work. Now we have no hesitation in saying that students might be able to pass very good examinations in Professor Goodeve's book, and yet not have an intelligent understanding of the theory of the steam engine. We would, therefore, strongly advise Professor Goodeve to consider the advisability of re-writing the whole work and arranging it in logical order. The book contains a large number of examination questions which will be found most useful, for, although we by no means believe in getting up a subject from old examination papers, we are of opinion that students should take every opportunity of testing the progress they are making, and of putting their knowledge into a definite shape, and this can best be done by working out well-selected examples of calculation in the different departments of the subject.

THE WORLD'S FAIR AT CHICAGO.

Above we give a bird's-eye view of the buildings which have been determined upon for the World's Fair at Chicago in 1893.

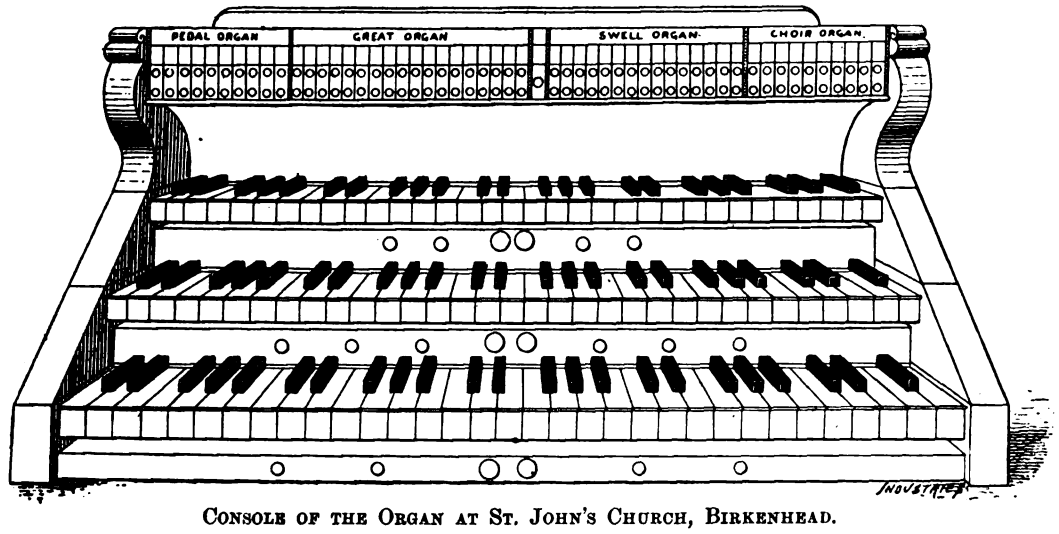
The Board of Architects, which includes ten of the leading representatives of the profession in the United States, has been at work for months upon the details of the great buildings. The general design has already been decided upon, and gives promise of a grand array unequalled at any previous exposition. The structures to be erected by the Construction Department alone, not including those by individual States, industries, or foreign nations, will cover more than a hundred acres of ground space, and consist at present of the following:—Machinery Hall, 500ft. long by 850ft. wide; Agricultural Hall, 500ft. by 800ft.; Administration Building, 225ft. by 225ft.; Mines, 350ft. by 700ft.; Electricity, 350ft. by 700ft.; Transportation, 250ft. by 960ft.; Manufactures and Decorative Arts, 788ft. by 1,688ft.; Horticultural Hall, 250ft. by 1,000ft.; Woman's Building, 200ft. by 400ft.; United States Government Building, 350ft. by 420ft.; Illinois State Building, 430ft. by 160ft.; Fisheries, 150ft. by 400ft. The designs of each of these buildings are being got out by a different architect, and the contract for the construction of each will be given out to different firms, so that no time may be lost in their erection.

A large pier stretching into the lake, and enclosing a harbour available for maritime exhibits, will form one of the features of the grounds. About 1,000 men are at present at work at Jackson Park, where it has been decided to locate the Exhibition, in excavating the lagoons, grading, and preparing the foundation sites of the buildings.

ELECTRIC ORGANS.

By James Swinburne.

The idea, and to some extent the application, of electricity to the mechanism of organs is not new. Gauntlett proposed to build models of various celebrated organs at the London Exhibition of 1851, and to connect them all to one console. Barker, the inventor of the pneumatic pallet, worked out what was probably the earliest practical system of electrically controlled organs.



An organ consists essentially of three or four independent instruments. Each instrument is composed of sets of pipes, called stops, arranged in rows, say, crosswise, on what is known as the "soundboard," probably because it is not a soundboard. The pipes are also arranged in rows from back to front, each row corresponding to a key on the keyboard belonging to that organ. Each key commands a valve, or pallet, letting wind into a channel under all the front to back row belonging to it. Each stop has a long perforated slip or slider running under it, which can be moved so that the holes correspond or not with those leading to the pipes. These sliders are controlled by the draw-stops. A fourfold organ has one pedal and three manual keyboards, called "great," "swell," and "choir." Further mechanism is necessary to connect various keyboards, and to admit of rapid changes of the arrangement of the draw-stops. This appears very simple, but when an organ has about forty stops, and over fifty draw-stops, it becomes very complicated. The first trouble is that it soon becomes almost impossible for the fingers of the left hand to work air valves or pallets large enough to control the wind for twenty or thirty large pipes, even if equilibrium valves are used. I am, as far as possible, using engineering, and not organ-building, nomenclature. To get over this, the air relay, or pneumatic pallet, has been adopted in large organs. The finger then controls a tiny equilibrium valve, which controls an air bellows that does all the work. When this system is applied to the great organ of a small instrument, it is generally arranged to work the "choir" and "swell," too, when coupled to the "great."

There is still another difficulty. In large instruments the pneumatic pallets frequently have to be a long way off the player, and the connections are apt to alter in length and get out of adjustment. In All Saints' Church, Manchester, there is, or was, an organ played from near the reading desk, placed high up on each side of the chancel, 70ft. off. It has mechanical connections, but they are not heavy, and seem to work very well. Generally, an arrangement like that used in pneumatic bells is used, and known as the tubular pneumatic system. Barker, however, controlled his little air relay valves electrically, and realised the advantages of electrical connections in admitting of great simplicity in coupling and key mechanism, as well as ease in connecting distant organs. The electric action, as it is called, has developed especially abroad. Messrs. Bryceson have done a great deal, and many English organs have electric connection. In France there are a large number of these combined electric and air relay mechanisms. M. Carré describes several in a valuable article in *La Lumière Electrique*. Roosevelt, in America, has not only developed pneumatic actions thoroughly, but has employed electricity too. The three-manual organ at Trinity Church, Boston, has not only pneumatic action for the keys, but a pneumatic stop action which admits of an exceedingly convenient composition pedal arrangement. The pedal on being pressed and hitched down draws its corresponding set of stops, and shuts them off again when allowed to rise, without interfering with any arrangement that has already been made. There is also an electric solo organ, but it was out of order when I tried the instrument. There is a concert organ by the same makers in Boston with a set of composition pedals, each with a complete set of draw-stops, which can be arranged beforehand, and come into use when the pedal is pressed. I believe the new Riga organ is electrical.

Mr. Hope-Jones has recently paid great attention to the subject of electric actions. Being an electrical engineer

ELECTRIC ORGANS.

CONSOLE OF THE ORGAN AT ST. JOHN'S CHURCH, BIRKENHEAD.

and an organist, he is well fitted for tackling such a difficult subject. There is given above an illustration of the console of the organ of St. John's Church, Birkenhead, where Mr. Hope-Jones is organist. Instead of draw-stops at the sides of the player there are rows of little tumblers just under the music. A touch at the top or bottom puts the stop in or out. This organ, if arranged in the ordinary way, would have about forty draw-stops. By the use of electric gear, Mr. Hope-Jones produces an organ which has the same effect as an instrument of fifty-three with the ease of manipulation of one of twenty draw-stops. In addition, it has a whole host of composition buttons, crescendo arrangements, and other accessories.

So far electricity seems to have been used to work an air relay only. The use of electricity may easily be carried very much farther than this. The difficulty has been the supply of electrical energy, and batteries have been used. Mr. Hope-Jones, who has had experience in telephone work, has probably reduced the energy needed to a minimum. It seems obvious, however, that to use electricity to work an air relay for working a valve needing a pull of a pound or two through half an inch is absurd; and our electrical readers may well study the question, as given, say, twenty watts available, the whole mechanism of the ordinary organ might be swept away, and an infinitely more convenient and much less costly instrument devised. It is easy to get the power. In England the blower, who does the whole of the work when air relays are used, works a thing like a pump handle up and down. In France he works two levers with his feet. Sometimes the blower is a water motor or a gas engine. All that is wanted is rotary motion. Even if rotary motion is provided, by means of hand cranks, water motors, or gas engines, the feeders are generally on the principle of a smith's bellows. We would suggest that such a machine as the Baker positive blower would be very much cheaper and better, giving a uniform supply without beating. The electric power can then be supplied by a very small magneto machine. This need have no commutator, it may supply alternating currents of low enough frequency to be silent. There is then nothing to get out of order, and owing to hysteresis, if closed circuit electromagnets be used, there is practically no sparking at the various contacts. Organ music is limited entirely by the mechanism of the organ and develops with it. In Germany they have only one sort of organ music, of which the works of Merkel, Rheinberger, and perhaps Mendelssohn may be taken as examples. This needs no accessory mechanism, and even modern German organs have, we believe, little as a rule. The well-known organ at Tyne Dock, by Schultze, has no composition pedals, and, if I remember aright, no couplers. In France the organ intersperses showy scraps during church service; and many of the organs are not designed for solid playing. The large organ at St. Eustache, for instance, has the pedals so arranged that the player cannot reach them without sliding along the seat. They have all sorts of arrangements for meretricious effects—tremulants, fancy reeds, and "effets d'orage." In England and the United States organ playing has got as far as it can without a change in organ construction. The average church organ spends its time in the monotonous accompaniment of hymns and chants, but the concert instrument plays German fugue music, German chorale organ music or the resulting German organ sonata; then it plays Guilmant and light French music; and then it indulges in a development which is essentially English, the organ arrangement. As much of an orchestral movement as can possibly be compressed into the region of ten fingers and two feet is crammed on three staves, and the organist has to change his stops as best he can. It is probably only in England and America that such things as the overtures to "Der Freischütz" or "A Midsummer Night's Dream" are played on organs. It is only because the mechanism does not give the right combinations quickly enough, if at all, that the overture to "Tannhaüser" does not figure on recital programmes.

It is difficult to think of all that can be done easily and cheaply by direct electric mechanism. If each key makes circuit with a set of small electric valves, one to each pipe, and if the returns to each stop are controlled by what corresponds to the draw-stop, all the ordinary mechanism of pneumatic pallets, expensive soundboards — which sometimes warp — trackers, sliders, rollers, &c., may be swept off. It may be remarked parenthetically that the abolition of pneumatic pallets is itself most desirable. Apart from expense, they tend to develop a bad style of playing. The organ cannot accent a note by playing it louder, so emphasis is given to it by clipping the note before it a little short. Phrasing thus depends on perfect instantaneousness of the action, which is not always found with the air relay. In a cathedral, organ music gets mixed up into a sort of roar which rolls down the aisles in a way poets like, and slovenly phrasing, does not matter, but in a concert room an organist accustomed to a large instrument generally bears evidences of it. With electric mechanism, any stop may be drawn on any manual, or prearranged for any manual and composition button. Any grouping may thus be adopted. In orchestral music, though there are about twenty staves in the score, the instruments fall roughly into a few groups. It should be easy to group the corresponding stops on the organ in the same way for playing orchestral music. This can be done by electricity. Again, in playing from the ordinary piano score of oratorios, there are four lines of voice parts, which demand one keyboard, and two lines of condensed accompaniment, which demand one or two keyboards, which must be coupled instantly to the voice keyboard when there are no hands available to play them. Existing organs generally meet these last requirements. Electric action admits of still another development. In a medium sized hall, one manual may be an ordinary grand piano. A piano could not be combined with an ordinary organ, because the touch is different; but if the console is detached from the organ so as to give breathing room for the piano, the addition of the contacts to the keys will not interfere with the touch of the piano at all. This suggestion will strike many as odd, some may say barbarous, but the harp may almost be considered part of the modern orchestra, and apart from concertos, the piano might also be absorbed too, especially if it were more portable, and several could be employed together.

Enough has been said to show the enormous advantages of simple organ mechanism. One great difficulty will probably be in organ builders themselves. They are often too apt to regard electric action as complicated, untrustworthy, and expensive. It must be remembered that electric work has advanced enormously within the last few years; and if electricity can sweep away the whole of the rest of the action mechanism from organs it is certainly worth consideration. The excellence of the organ at Birkenhead points to the advisability of organ builders going to electricians to get the electrical part of their actions put right, instead of designing it themselves, and then rejecting it as costly or untrustworthy.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

(*From our New York Correspondent.*)

THE annual meeting of this Institute took place at New York on the 19th, 20th, and 21st ult. The business meeting, at which officers were elected for the ensuing year, was held on the 19th ult. The report of Council showed a continuation of the growth in membership, which has now reached a total of 541. Professor Alexander Graham Bell was elected President.

The first paper on the 20th ult. was by Professor F. B. Crocker, on "The Perfection of the Stationary Electric Motor." He classified motors in three types—for long distance transmission, power distribution, and railway work—but directed his attention especially to the stationary motor for distribution. The base, he said, should be a solid iron casting, flat and simple in form, resting directly upon the base frame or floor, which should be preferably of wood for insulation. The base should be heavy to bring the centre of gravity low. A heavy base gives great stability and strength to the whole machine, and is highly desirable in a stationary motor. The bearings should be directly and rigidly mounted on this base, a simple fact frequently disregarded. The field magnet should be bipolar, except in machines above 10 h.p., on account of the great complications caused by a number of armature sections, commutator bars, field coils, &c., necessary in multipolar machines, and the narrowness of the neutral space on their commutators. The field should be of the single magnetic circuit rather than consequent pole type, the former being more economical in wire and current required. A single circuit requires but 70 per cent. of the weight of wire and 70 per cent. of the energy of magnetisation required by a double magnetic circuit. A triple or quadruple magnetic circuit is still more objectionable, requiring about double the wire of a single core of the same total cross-section. There is no objection to using the cast-iron base to complete the magnetic circuit, its ample weight and cross-section affording ample magnetic permeance, and it does not increase the leakage, being magnetically neutral. The field cores should be of wrought iron, because the field wire surrounds them, and if of cast iron would require almost double the cross-section, and therefore, greater length of wire. The pole pieces should also be of wrought iron to reduce their size and also magnetic leakage, they being at the highest magnetic potential of any part of the machine. Since any considerable fitting of wrought iron is difficult and costly, it is best to drop forge the core and pole piece in one part, which permits forming the armature space at the same time. In order to secure sufficient contact and strength, these cores should be set into the cast-iron base, as the ordinary butt joint limits the magnetic conductivity. The supposition that cast iron is cheaper than wrought for magnets is a fallacy. The ring armature is difficult to support mechanically, but the winding does not tend to slip out of place or pile up at the ends, and wires of greatest difference of potential come at the greatest distance apart—that is, on opposite sides of the armature—which is of the greatest importance in high voltage machines. In the case of small ring armatures, where a great number of turns of wire are used, the ring should be split in halves to facilitate winding, and put together afterwards when wound. The armature should have teeth or projections in order to secure the following advantages:—First, to reduce the reluctance of the magnetic circuit, and the weight of wire and energy of current required to magnetise it. Second, to hold the wires in place and prevent them slipping tangentially on the core. Third, the teeth protect the wires from mechanical injury, since any blow or pressure comes upon them instead of the wire. In the trapezoidal tooth armature, the teeth are considerably wider at the top than at the bottom, which, of course, makes between the teeth a slot wider at the bottom than at the top. This shape of tooth and slot has the following advantages over the ordinary form:—First, the wire is more secure, being held against centrifugal as well as tangential force; second, the wire is more perfectly protected, being almost entirely surrounded by iron; third, the armature presents an almost unbroken magnetic surface to the pole pieces, reducing to a minimum the reluctance of the air spaces in the magnetic circuit, and the magnetic leakage, and avoiding Foucault currents and loss of energy in the pole pieces. This form of slots and teeth can be still further taken advantage of by giving the slots a shape agreeing with the form of a section of the winding inside of a ring, the interior spaces for winding being divided into the necessary number of sections by radial lines. This form of slot is especially economical in winding, there being a greater number of turns in the inner layers which are shorter, and fewer turns in the outer which are longer. The teeth make it easy to support the ring

Digitized by Google

since the bolts for carrying it may pass through the teeth without interfering with the winding. Perfect insulation of the armature core is of the utmost importance. The efficiency should be made as high as possible by reducing such elements of loss as are due to current to magnetise field, armature resistance, friction, resistance of air, Foucault currents, and hysteresis. If a machine can run two hours at full load without overheating in any part, the efficiency must be high, unless it is very large and heavy for its power, in which case the surface for conduction and radiation would be great. The following is a table of data of a 3 h.p. motor constructed in accordance with the principles laid down:—

Total weight	350	lbs.
Weight of field wire (No. 24, A.W.G.)	12	lbs.
Weight of armature wire (No. 13, A.W.G.)	11	lbs.
Resistance of field	310	ohms
Resistance of armature	·4	ohms
E.M.F. of circuit	115·	volts
Total current at full load	24·3	amps.
Current used to excite field	·37	amp.
Percentage of current used in field	·015	
Total current required to run free	1·9	amps.
Percentage of total energy to run free	·08	
Commercial efficiency	·80	
Armature speed	975·	r.p.m.
Total magnetic leakage or waste lines of force	·17	
Magnetic efficiency = Lines through armature / Total lines of force	·83	

In the discussion which followed, Professor Thomson pointed out that in order to secure a large amount of surface in a joint between cast and wrought iron, it was necessary to use a flange or something of the kind. The plan suggested in the paper secured the same result by practically taking out some of the cast iron and inserting the wrought iron.

Mr. Mailloux agreed with the author that the lamination of fields and pole pieces was not only expensive, but very unsatisfactory, mainly for mechanical reasons. He also called attention to the fact that the shape of the teeth, their number, clearance, &c., had an influence on the sparking. He believed that a motor could be made as efficient at low as at high speed if made sufficiently large. He would have been glad to have seen more attention paid to such data as would be useful to electricians, as in mechanical engineering, where everything is reduced to formula. It would have been interesting to learn the ratios of speeds to surface—the ratio of watts dissipated to surfaces on which they were dissipated. It would have been instructive to learn the percentage of heat wasted in the field in relation to the surfaces in action.

Mr. J. Martin said it was the former practice of the Edison Company to fit the surfaces of cores and yokes as accurately as possible, but now they were simply planed or turned off. The practical value of continuous and reliable running, regardless of efficiency, was important, as the users, when pressed for work, would rather pay quadruple rates for power than have the machinery stop for even a few moments.

A paper was afterwards read by Dr. E. L. Nichols, of Ithaca, entitled "A Photographic Study of the Electric Arc," based on experiments by Mr. J. C. McMynn. The alternating arc, and the continuous current arc, he said, afforded two distinct fields of investigation. The arc lamp fed by alternating currents invariably hums and sings. The note possesses a definite pitch determined by the rate of alternation of the dynamo, and is not due to the mechanism of the lamp itself. The Jablochkoff candle without mechanism sings as merrily as the lamp with a solenoid regulator. Investigation had satisfied him that the humming of the alternating arc was due to the rapid periodic extinction and re-establishment of the discharge. The paper was accompanied with reproductions of photographs, establishing the intermittent character of the alternating arc.

In the discussion Professor Elihu Thomson doubted that it could be argued absolutely that there was a cessation of the arc because the photograph appeared to show it. The current flowing might be so small as not to give actinic luminosity to the stream.

Dr. Nichols replied that the photographic results were confirmed by observations with a revolving mirror.

Mr. Carl Hering then read a paper on "A New Graphical Method of Calculating Leads for Wiring." The general principle laid down was that for any formula containing three variable quantities, one of which was the product on the quotient of the other two, the "curves" representing their relative values may always be represented by a series of straight diagonal lines drawn through the centre or zero point. Such a set of lines would therefore enable one to make any calculations graphically for that formula.

After this, Professor Edwin H. Hale, of Harvard University, gave a description of his "Thermo-Electric Method of Studying Cylinder Condensation in Steam Engines." He inserted a ¾in. plug in the cylinder wall, in which is set a plate of antimony and another of bismuth, making the best known thermo-electric pair, but, on account of the low conductivity of heat, he afterwards substituted iron and nickel. Wires are led to a galvanometer, and the variations of heat in different parts of the cylinder are determined by fluctuations in current from corresponding plugs. Although the method is not entirely perfected, it has shown sufficient merit to warrant further investigation.

A paper by Dr. F. A. C. Perrine, dealing with "The Practical Aspects of Electric Welding," was then read, and was a review of the various industrial applications of the process, and samples were exhibited by different establishments. There were steel wheels in which all the spokes are welded to the hub at one operation, parts of type-setting machines, in which brass and steel were welded together, parts of bicycles brazed by electrical heat, and fifth wheels of carriages, in which the electrical process effects a great saving of time and labour. One of the machines, used two years for jointing wire, had made 370,000 welds in that time, and by finishing off the joints with an emery wheel the writer stated that the telegraph experts found it impossible to locate them. Difficulty had been experienced in satisfactorily welding cast steel and malleable iron. In discussing the paper, Professor Thomson, the inventor of the process, said that its development had been principally in a line of work where the ordinary welding could not be utilised. There was a natural reluctance in the adoption of such a revolutionary method, and even those who favoured it were inclined to see it thoroughly tested by others before abandoning a well-tried process and incurring unusual expenses.

In the evening Mr. Nicola Tesla delivered a lecture on "Experiments with Alternating Currents of High Frequency"—of which we conclude a special abstract below. The experiments shown were very impressive, and Mr. Tesla is sanguine that they will lead to practical results in electric lighting, although he admits the difficulty of insulation.

(To be continued.)

EXPERIMENTS WITH ALTERNATING CURRENTS OF HIGH FREQUENCY.*

(Concluded from page 546.)

Mr. Tesla showed a lamp with but a single rod filament in a non-striking vacuum with no outward connection. The energy is entirely transferred by condenser action through the medium of condenser coatings in the base of the lamp. He also pointed out how the brilliancy of the lamp could be varied by simply altering the relative positions of the condenser coatings. This the lecturer followed by demonstration of the phenomena with an unexhausted globe, and a single filament mounted therein. The filament when connected to one terminal of the coil heats up to bright incandescence and spins around in the globe. He also demonstrated the heating by the use of Crookes' well-known apparatus consisting of mica vanes mounted above a platinum wire, which was brought to incandescence by connection with one terminal of the coil, and rotated the mica vanes. In order to still further verify the conclusions that the electrostatic effects are alone active, the lecturer placed a Geissler tube at right angles to the coil and at its centre. In this position the tube did not light up. When placed at the ends, however, the tube lit up brilliantly and gave sufficient light to read by. The lecturer showed both uranium and yttria tubes. He then showed how exhausted tubes could be made to glow in an electrostatic field. For this purpose two large sheets of zinc were connected to the terminals of the machine at a distance of about 15ft. apart. The tube when placed between these sheets glowed brilliantly and could be moved about freely. The lecturer remarked that, by merely creating such a field in a room, the mere suspension of the tubes in the room would afford the desired illumination.

Coming to the physiological effects, Mr. Tesla adjusted the conditions so that by touching one terminal with a brass sphere he raised the potential of the coil so enormously that a stream of light came out on the other terminal, and he estimated the difference of potential to be nearly 250,000 volts, and then performed the remarkable experiment of receiving the total discharge in his body, protecting his hands from burning by the brass balls held in his hands. He then lit up lamps by holding them in contact with one terminal or near to the coil.

The lecturer then came to another class of experiments. He stated that he had used a system of conversion from high tension to low with the enormous frequencies of the condenser discharges. Mr. Tesla then showed an interesting experiment, which consisted in passing the converted currents, produced in the manner just described, through a copper bar ⅜in. in diameter and bent into a loop. Ordinarily such a bar would constitute a short circuit, but the lecturer succeeded in bringing lamps stretched across the parallel sides of the bar to incandescence, demonstrating that the impedance in the loop connecting the two sides was so great as to practically prevent the current from passing through it and hence acting upon the lamps in the manner described. He also pointed out the existence of modes on the bar. His method consists in continuously charging and disruptively discharging a condenser into the working circuit, the charging of the condenser being effected by a coil operated either by alternating or direct currents. By this means any desired higher frequency may be obtained from any lower frequency.

The foregoing gives but the merest outline of the many beautiful and highly suggestive experiments made by Mr. Tesla. Notwithstanding the fact that Mr. Tesla excited the intensest interest of his audience for three hours, he was, nevertheless, unable, for lack of time, to bring before them many experiments, some of which, he said, were even of a more striking nature than those brought out.

* Abstract of a recent paper read by Mr. Nikola Tesla before the American Institute of Electrical Engineers. For the above abstract we are indebted to our American contemporary the *Electrical Engineer*.

CELLULOID AND ITS MANUFACTURE.

Considerable progress has recently been made in perfecting the manufacture of celluloid, and the growing demands for a cheap substitute for bone and ivory has caused several new manufactories to spring up for the production of this preparation in recent years. Since celluloid possesses the important advantage over the materials which it is intended to replace in being capable of being moulded, coloured, and worked into any desired shape, it has been adopted for many articles which previously were made of more valuable materials. Mathematical instruments are now largely made from celluloid cloth, formed by coating linen or pasteboard with this composition, and as its coefficient of expansion is very uniform instruments made of it are to be preferred to those made of even the best-seasoned box-wood. Although first manufactured by the Hyatts in America, in 1869, the manufactory established by them at Stains, near St. Denis, in 1876, was the first factory of any importance, and France since that date has possessed a number of smaller works devoted to the production of this article. In that country celluloid is made from a solution of camphor and nitro-cellulose in alcohol, whilst in Germany, in addition to the alcohol, ether is employed as a solvent.

The paste formed in this way is gently warmed, and then rolled out into thin sheets, and in this state loses the last portions of its volatile solvents. The product so ground is a brittle, transparent, horny mass, consisting of either an intimate mixture of camphor and pyroxyline or possibly of a chemical compound of these two bodies. H. Bockmann gives the following analyses of two samples of this material:—

	German.		English.
Nitro-cellulose	64·89	...	73·70
Camphor	32·86	...	22·79
Colouring matter	2·25	...	3·51
Total	100·00	...	100·00

The former of these is met with in commerce in rods, whilst the latter occurs in blocks.

The nitro-cellulose used for this manufacture is obtained by nitrating paper, cotton wool, or wood shavings. A mixture of two parts sulphuric acid and one part fuming nitric acid at a temperature not exceeding 22° C. gives the best results. In some works a mixture of 115 parts of sulphuric acid, sp. g. 1·84, and 93 parts of nitric acid is heated to 80° C., and cotton wool plunged into this bath for a few minutes, and then withdrawn and well washed. This product is entirely soluble in alcohol. Should the nitration be incomplete, a mixture of alcohol and ether will fail to completely dissolve the nitrated cellulose.

Unless the cellulose used has been previously bleached, it is absolutely necessary to perform this operation after nitrating. The nitro-cellulose is disintegrated, washed with carbonate of soda, then with water, and finally transferred to truncated bleaching tubs holding about 10 cubic metres (2,200 gallons). These vats are provided with perforated copper bottoms, through the centre of which pass agitators. The washed nitro-cellulose is added, with three times its volume of water containing 2 per cent. of potassium permanganate; it is left for about an hour, when a fresh quantity of water is added. Then, after standing for half an hour, a strong brine is added, together with some hydrochloric acid. This mixture is allowed to react on the pyroxyline for an hour; then the whole mass is thoroughly washed, first with water, and finally with sulphuric acid, to remove all foreign matters.

The pyroxyline thus prepared, when freed from acid, is carefully dried, cut into small fragments by special machinery, mixed with camphor, and reduced in a suitable mill to a fine powder, about 40 per cent. of water being added to prevent the pyroxyline taking fire. The meal obtained is compressed by a hydraulic press into cakes, which are subsequently broken into fragments and transferred to a closed vessel, where they come in contact with from 15 to 35 per cent. of alcohol of 96 per cent. In twenty-four hours a gelatinous mass is obtained, which is then generally spread out by hollow rollers heated internally by steam to keep the temperature of the exterior surface at about 60° C.; this rolling is continued between cylinders more and more closely set together until a sheet is obtained about 12 mm. thick, having the required resistance and consistency.

In order to expel air bubbles from these sheets, heat and a hydraulic press are used, and finally the celluloid is again compressed in the cold into large blocks, which

Digitized by Google

can be easily stored. When the celluloid is sent out into commerce, these blocks are split into leaves, more or less thick, by means of special planes, or by circular saws moistened with steam. After this treatment the cut leaves are placed in ventilated drying rooms, kept at about 90°. At the end of twelve hours the material is dry enough for sale. Crude celluloid is a transparent horny substance of a pale yellowish colour, with a characteristic odour of camphor; its specific gravity varies between 1·25 and 1·45. It is softened by heat, and is then capable of receiving an impression. At 90° C. it becomes very plastic; further heat softens it, and a temperature of 140° C. decomposes it into pyroxyline and camphor aldehyde. At 195° C. the decomposition is instantaneous; the nitro-cellulose inflames and the camphor is vaporised.

Celluloid is readily inflammable and burns with a crackling flame; on blowing, the flame is easily extinguished, but the mass continues to burn, liberating thick vapours of camphor. It is not affected by concussion, and does not detonate even in contact with fulminates. Sulphuric acid decomposes it rapidly on warming; hydrochloric acid has a much slower action. Nitric acid attacks it slowly in the cold, very rapidly when warmed, and soda lye acts similarly. If it is desired to imitate either marble, ivory, or tortoiseshell in celluloid, it must be coloured uniformly or with layers of different tints. In the first case the colouring matter is incorporated with the mixture of pyroxyline and camphor, for which purpose mineral colours are generally employed. In the second case, different tinted celluloids in the gelatinous state are prepared, and then united to form the desired object having a required colour, the harmonious blending of the colours depending entirely upon the skill of the workmen.

The amount of camphor in a sample of celluloid can be estimated by the following process, due to F. Foerster, and described in the *Berichte*, XXIII., 2981-2989. A weighed quantity is heated with caustic soda, and the solution distilled with steam; the camphor volatilises, and may be taken up from the distillate by means of benzene. The rotatory power of the benzene solution affords a measure of the amount of camphor present. The process is conducted as follows:—Enough celluloid to yield 2–3 grammes camphor is weighed out into a litre flask fitted with a dropping funnel and connected to a condenser. To the condenser is fitted a special receiver to collect the distilled camphor. Sufficient 10 per cent. soda is added by the funnel to saponify the celluloid, and the flask is heated in the water-bath to 80° C. When saponification is effected, a more concentrated solution of caustic soda is run in until the solution contains 10 per cent. of soda. The mixture is then boiled and the camphor distils over. When 120 c.c. have come over (which fills the lower ball of the special receiver), the distillation is stopped, and the distillate, made up to 150 c.c., is extracted with 25 c.c. to 30 c.c. of benzene. The rotating power of this solution is then determined at 20° C. by means of a Laurent's half-shadow polariscope with a 400 mm. water-jacketed tube. The quantity of camphor in the solution is given by the following formula, deduced by Foerster from experiments made with pure recrystallised camphor:—

$$[\alpha]_D = (39{\cdot}755 + 0{\cdot}17254\,C)^0,$$

where $C = \frac{100\alpha}{l[\alpha]_D}$, in which l is the length of the tube in decimetres. Substituting the above value for $[\alpha]_D$, C (or the amount of camphor per 100 c.c.) becomes—

$$C = 115{\cdot}2052\left(-1+\sqrt{1+0{\cdot}0436683\,\frac{\alpha}{l}}\right)$$

Landolt found the value for $[\alpha]_D$ to be—

$$[\alpha]_D = (39{\cdot}185 + 0{\cdot}17084\,C)^0,$$

using camphor purified by sublimation, but Foerster states that a certain amount of decomposition takes place in this process, and that two recrystallisations from 50 per cent. alcohol yield a pure product.

The following results show the accuracy of Foerster's formula:—

Camphor Found.	Camphor calculated to Formula.	Difference.
5	5·0010	+ 0·0001
10	9·9894	− 0·0106
15	14·9982	− 0·0018
20	19·9915	− 0·0085
30	30·0037	+ 0·0037
40	39·9700	− 0·0300

Zaunschirm has also recently pointed out in the *Chemiker Zeitung* that celluloid can be conveniently analysed by dissolving ·2–·3 grammes in 5 c.c. concentrated sulphuric acid in a nitrometer, and measuring the volume of nitric oxide evolved. He assumes that commercial dinitro-cellulose is used in its manufacture, which yields 10·5 per cent. of nitrogen instead of 11·1 per cent., which is the theoretical quantity.

Notes.

LIME AND CEMENT MANUFACTURE IN ALGERIA.

An important industry which has sprung up near Bougie, in Algeria, is the manufacture of hydraulic lime and cement. There are six kilns constantly at work now, consuming from 10 to 12 tons of English coal per day, and producing 70 tons of lime and 30 tons of cement.

THE SILK INDUSTRY AT LYONS.

The year 1890 was not a very encouraging one to the silk industry at Lyons, a falling off of over 12½ per cent. in the production of the previous year having to be recorded. The year was characterised by the struggle between silk-growers, spinners, and throwers, who desired to impose a protective tariff, and the manufacturers of Lyons and St. Etienne, who viewed such a proceeding as ruinous to the trade.

ELECTRICITY METERS.

The committee appointed by the City of Paris to award the prizes in connection with the exhibition of registers of electrical energy has just made its award. The first prize, £400, has been divided between the Aron and E. Thomson meters, which are said to have given great satisfaction, and to be applicable both to continuous and to alternating currents. The apparatus of M. Frager receives the second prize—£40, as applied to continuous currents, and £40 as applied to alternating currents. The third prize, £40, has been awarded to the Marès register, as applied to the measurement of continuous currents.

THE USELESS PRODUCTION OF TENDERS.

Mr. S. F. Walker has sent us a proof of an able article, written by him for our contemporary the *Electrical Engineer*. He points out the enormous waste of money under the present system, where a number of firms are asked to tender, not only in cases where it has been already practically settled who is to have the order, but also where no order is to be given. The practice of asking for tenders when anyone wants to know the price of certain things is only too common, and, as Mr. Walker points out, the cost of preparing estimates eventually comes on the public in the long run. We are afraid, however, that Mr. Walker's proposal of charging for tenders will not come into use. In fact, contractors have often to pay for specifications.

AN ELECTRICAL ENGINEERING EXHIBITION AT TAUNTON.

An Electrical Engineering Exhibition is to be held at Taunton during the months of August, September, and October next, on the grounds adjoining the Taunton Electric Lighting Company's Central Station. The Exhibition will comprise the following:—(1) Lighting by electricity; (2) heating by electricity; (3) machines, &c., for producing electrical currents by mechanical power; (4) electric motors and their applications; (5) electric welding and brazing; (6) electric batteries—primary and secondary; (7) apparatus for electrical measurements; (8) the phonograph; (9) the telephone; (10) electric telegraphs and electric signals; (11) electricity in surgery; (12) electro-plating; (13) applications of electricity in various ways not specified above; (14) steam engines, pumps, &c.; (15) gas and oil engines; (16) models of all descriptions. Applications for space are to be sent to the Secretary of the Exhibition, Mr. Harry C. Willson, Bath Electric Light Works, Bath.

"JOSS-STICK POWDER."

Last year, amongst the exports of the Chinese port of Wuhu was an item "joss-stick powder," to the amount of more than 3½ million pounds weight. This is one of the peculiar articles of Chinese trade. It is sometimes called "native putchuck," and from it are made the small sticks of incense used largely by the Chinese in their religious ceremonies. Its production, according to a recent Consular report, in the southern portion of the province of Ganhui is very considerable, being estimated at nearly 30,000 tons annually. It varies very much in quality, the best, which is made from the bark of a species of elm, being valued at about 18s. a cwt., while the bulk of the production is most inferior, being made of refuse and twigs of all kinds, and is scarcely worth 1s. a cwt. Formerly what went out of the province was taken chiefly by native boats paying duties to the native customs, and the quantity that passed through the Imperial Maritime Customs was comparatively small, and confined to the better qualities. Last year it would seem to have occurred to some merchants in Chinkiang to effect a saving by bringing it down from the interior under the protection of transit passes. The authorities of that port, however, refused to issue these passes for "Joss-stick powder" on the ground that it is not one of the articles to which the issue of such passes is, by the rules in force in Chinkiang, restricted; and this drove the merchants into trying what effect applying for the passes at Wuhu would produce. No objection was made to the issue of the passes by the Chinese authorities there, and thus it came about that the export in 1890 rose to over 32,600 cwt.

SIMLA WATER SUPPLY.

The detailed project for pumping water into Simla during the dry months, prepared by Mr. A. Younghusband, has, states *Indian Engineering*, been approved and forwarded to the Government for sanction by the municipality. The total cost of carrying out the works is estimated at Rs.4,85,000, and the annual working expenses in a very dry year at Rs.15,614. The Government has been asked to give a free grant towards the initial cost of the work. In the event of the Government being unable to give a free grant of the amount required to carry out the work, Government is asked to lend the amount required, approximately 5 lakhs, on interest at 4 per cent. per annum. In order to cover the annual cost of working, the Committee will, if the Government approve, make proposals regarding a water rate. The maximum sum required will not exceed 2 per cent. on the assessed value of house property in Simla, including that in the bazaars.

THE PORT OF DULUTH, ON LAKE SUPERIOR.

The port of Duluth, on Lake Superior, is rapidly growing in importance. The total arrivals and clearances amounted, in 1890, to 2,534 vessels, with an aggregate tonnage of 2,740,354 tons, more than double the tonnage of five years ago. The receipts by lake, according to the Customs returns, consist chiefly of coal, cement, lime, salt, and railroad iron, and amounted to 1,000,923 tons; and the shipments, chiefly wheat, flour, other cereals, and iron ore, aggregated 1,079,131 tons; but this in some respects does not represent half the real trade of the place, as the manifests of vessels landing part of their cargo at Duluth, and then proceeding to Superior, are surrendered at the latter port, which is thus credited with much that is landed at Duluth. The same custom is followed with outward vessels, which, clearing light from Superior, are not credited in the Customs records of Duluth with the cargo taken from that port. Superior, or West Superior, still further west than Duluth, only came into existence quite lately, and is fast rising into an important shipping port.

RAILWAYS IN RUSSIA.

The statistical report of the Minister of Communications in Russia, recently published, sets forth that, although the gross receipts have slightly diminished as compared with 1888 and 1889, the net receipts were higher in 1890. The length of road in miles, with the passengers carried, and earnings, in roubles, for the past five years have been as below:—

Year.	Miles of Road.	Passengers.	Earnings. Roubles.
1886.....	16,388	34,330,683	222,087,481
1887.....	16,912	34,757,926	249,692,074
1888.....	17,422	36,773,818	279,444,317
1889.....	17,702	38,740,577	276,357,278
1890.....	18,158	39,754,241	275,830,889

The State owns 5,338 miles of road and 12,820 miles are owned by companies. The largest increase of traffic, 22 per cent., was on the Trans-Caspian Road. Extensions are said to be contemplated, amounting in all to 20,000 miles, and the matter is now under consideration. Permission has been given for the construction of a line from Riazan to Kazan by the Moscow and Riazan Railway Company. The line, which will be 300 miles in length, will be commenced as soon as practicable. It has also been decided to construct a line from Koorsk to Voronezh, which will be 200 miles long. All the railways planned for construction during the present year will be built by private companies, and not by the Government, which is sufficiently occupied with the support it is giving to the Siberian and Petrovsk Railways.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

25th May, 1891.

8813. Greening & Barringer — Automatic stop valve.
8818. Rennie, D. — Furnaces for melting metals.
8819. Bevan, W. — Annealing apparatus applied to heating furnaces.
8820. Fielding, J. — Compound duplex pumping engine.
8821. Shillito, T. R. — Igniting tubes for gas and petroleum motors (*Grob, Schultze, & Niemczik*).
8824. Zimer, F. W. — Treadle and hand-driving mechanism.
8825. Parini, G. C. — Propellers for vessels.
8826. Spencer, J. W. — Stern frames for ships.
8832. Johnson, J. — Fire-doors for locomotive boiler furnaces.
8826. The Rovello Syndicate, Ld., & Howell — Apparatus for the manufacture of wire.
8837. The Rovello Syndicate, Ld., & Howell — Apparatus for obtaining copper.
8838. Ritson, G. A. — Rotary engines.
8842. Jacobsen, A. — Bottle-filling machines.
8843. Jacobsen, A. — Apparatus for filling bottles.
8847. Gardner, H. — Machinery for sawing metals (*Hanford*).
8855. Lombard, N. — Cross-head blocks for engines.
8856. Kennedy, J. — Machinery of boom dipper dredges.
8859. Thompson, Ramsay, & Thompson — Steam and pressure gauges.
8860. Walsh, J. E. — Floating cranes and elevators.

26th May, 1891.

8875. Mead, J. J. — Lime-grinding mill.
8884. Massey & Hitchen — Number and weight indicator.
8886. Noton, W. — Scutchers for preparing cotton.
8887. Jacob, F. — Hand tools of the Archimedean drill type.
8902. Harris & Shuttlewood — Machines for making double-rib warp fabrics.
8915. Newton, P. A. — Apparatus for mounting and working ordnance (*Littlejohn*)
8933. Sternbergh, J. H. — Machines for punching, shearing, and the like.
8938. Johnston, A. — The manufacture of paper and mechanism connected therewith.
8940. May, W. de C. — Piston valves for steam engines.
8949. Thompson, W. P. — Boiler furnace grates (*Kudlicz*).
8953. Smith, J. — Regulating or controlling the flow of liquids.

27th May, 1891.

8999. Tyler & De Vesian — Apparatus for raising sunken vessels.
9000. Johnson, J. Y. — Machinery for cutting wood (*Frois*).
9004. Leaker & Bonne — Apparatus for drying grain.
9005. Stott & Stott, Jun. — Steam boilers.
9006. Boult, A. J. — Gas, petroleum, or carburetted air engines (*Lerasseur*).
9008. Hall, J. C. (of the Halton Engineering Company) — Valves.
9009. McCulloch, J. McG. — Steam boilers.
9010. Boult, A. J. — Filtering apparatus (*Wackernie*).
9016. Redwood & Redwood — Apparatus for measuring depth of water in oil tanks.

28th May, 1891.

9038. Southall, J. — Gas and oil engines.
9040. Walker, G. B. — Heading and tunnelling machines.
9045. Lucas & Yeomans — Cyclometers.
9046. Frotscher, L. — Steam press for woven fabrics.
9059. Moncrieff, R. W. — Paper-making machines.
9065. Newton, P. A. — Duplex engines (*Worthington*).
9080. Wade & Cherry — Means for use in indicating, communicating, and economising motive power, and in preventing shocks to machinery.

29th May, 1891.

9084. Murrie, J. — Apparatus for raising liquids and for feeding water into steam boilers.
9093. Wilson, W. — Steam engines.
9100. Walkerdine, A. — Apparatus for lubricating loose pulleys.
9101. Townend, W. — Jacquard looms.
9109. Ford, J. — Self-acting water feed supply to boilers.
9116. Lohr, H. — Spigot valves.
9120. Robertson & Miller — Permanent way of railways.
9124. Azzeroni, G. — Steering gear.
9125. Courlander, L. — Device for expanding or contracting rings.
9130. Pickard, A. — Apparatus for drilling square or other shaped holes.
9140. Miller, G. W. — Faucets for measuring fluids.
9146. Hunt & McKechnie — Setting out or aligning engines.

ELECTRICITY.

25th May, 1891.

8830. Kingdon, J. A. — Transformers.
8845. Haddan, R. — Galvanic batteries (*Cabanyes*).
8863. Lake, H. H. — Rheostats (*Lacombe & Co.*).

26th May, 1891.

8872. Bennett & Hides — Galvanic batteries.
8876. Hoster, A. — Recording mechanism.
8892. Adams, J. H. — Dynamos.
8896. Bolton, R. — Controlling the operation of machinery by electromotive power.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Steam Engines.—*W. T. Lord, London.*—The fluid pressure engines constructed according to this specification are fitted with trunk pistons containing a cylindrical or other oscillating valve having the necessary ports and passages, and adapted to receive and distribute the working fluid. Upon the trunk piston is fitted a tubular extension, for the purpose of conveying steam from the steam chest to the oscillating valve for distribution. The example illustrated below in sectional elevation is that of a single-

acting compound engine, in which A is the low-pressure cylinder containing the trunk piston B. The upper portion C of the engine casing carries a cylindrical chamber D constituting a steam-chest, and being fitted at its lower end with packing in order to make a steam-tight joint with a second trunk carried by the main trunk piston B, the chamber E within the second trunk forming the high-pressure cylinder. In the lower end of the steam chest D is an opening fitted with a gland, through which the inner steam supply tube F works. Steam from D passes through the openings G in the tube F, and through the passages in the oscillating valve H into the high-pressure cylinder, and, the engine being thus set in motion, the valve H is oscillated and presently allows steam to exhaust from the high-pressure cylinder into the interior of the valve H, during which latter operation the low-pressure cylinder is open to exhaust by the passages I, J, K, and L. A further movement of the valve allows the steam from the interior of H to pass by the passage M into the low-pressure cylinder. A relief valve N is placed in the wall between the valve chest and the high-pressure cylinder, to relieve any excessive back pressure in the latter. Several modifications of detail are described, but the principle and mode of operation of the engine is sufficiently made clear in the foregoing. Claims: A trunk piston having one or more tubes attached thereto as steam passages, and containing an oscillating valve; a trunk piston containing an oscillating valve which also forms a steam reservoir; the combination of a relief valve with arrangement of pistons and valve chest described; the arrangement as a whole.—No. 10488. July 7th, 1890. 6*d.*

Injectors.—*R. G. Brooke, Blackpool.*—This invention relates to an improved injector which, when applied in position for use on a boiler, has the combining nozzle, or the delivery nozzle, or a portion of each, or both, within the boiler shell. The improvements also relate to injectors in which the steam nozzle is so arranged that it can be longitudinally moved to control the supply of the water or steam. The accompanying illustration shows in Fig. 1 a longitudinal section, and in Fig. 2 a transverse section, of an injector so constructed that the delivery nozzle and a part of the combining nozzle are within the boiler. A shows the casing which by means of the flange B is secured to the boiler shell, C is the steam inlet branch, D the steam nozzle, E is the water inlet branch, and F the overflow outlet leading from the overflow passage G. On the inside of the boiler shell is the ordinary combining nozzle H and the delivery nozzle I connected to a tubular

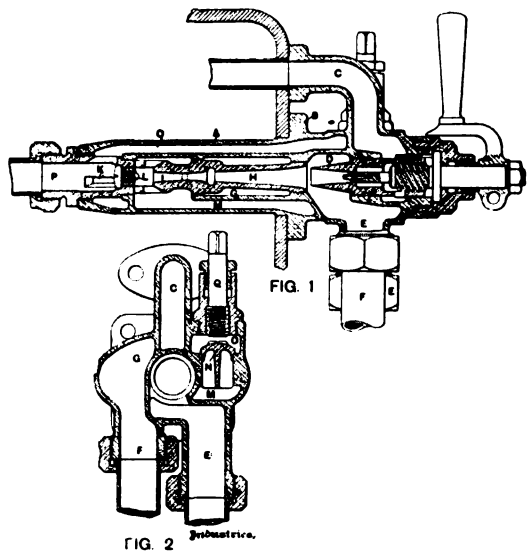

FIG. 1

FIG. 2

bush having two sets of openings J and K, and a diaphragm L between them, closing the direct passage through the delivery nozzle. One set of the openings J lead by the passage M through a non-return valve N, and along the passage O into the other openings K, and thence through the open delivery P into the boiler. The valve N can be held closed by a screw spindle Q. The specification shows other modifications and applications of this invention, among which is one of the type known as an "automatic self-starting injector." Claims: Attaching an injector to a boiler shell in such a manner that a portion of its casing projects into the boiler, and in which the discharge passes through a non-return valve, thence by a passage to the end of the injector casing located within the boiler.—No. 10164. July 1st, 1890. 11*d.*

Making Tubes.—*F. J. Jones, Bedford, Herts.*—This invention relates to a method of making tubes or cylinders of any desired length and diameter, of copper, its alloys, or of aluminium, without a longitudinal seam. The process consists in simultaneously winding a flat strip of metal in spiral convolutions, and welding or soldering together the abutting edges of the convolutions by electricity, the heated edges being pressed towards each other. In making bent pipes the strip would be of varying width, its edges being of sinuous form, according to the position each part of the strip will occupy in the circumference of the pipe, so as to produce a bend of uniform thickness of metal at all points. By substituting a spiral seam for a longitudinal one, the resistance of the joint to rupture is greatly increased. Fig. 1 is an end elevation partly in section, and Fig. 2 a plan, of an apparatus for making straight tubes in which the winding of the metal strip is effected by a mandrel A carrying a collar B of unglazed porcelain or other material upon which the strip is wound, the mandrel being driven by suitable gear, the standard at the far end being removable to allow of the tube being taken off the mandrel. A second collar C of metal of same diameter as B is fitted with a feather connection so as to rotate with and be free to slide on the mandrel A. It is furnished with clamps D by which the leading end of the strip E is made fast for the purpose of winding it by the rotation of the mandrel A. F is a helical guide for the strip, having a pitch corresponding

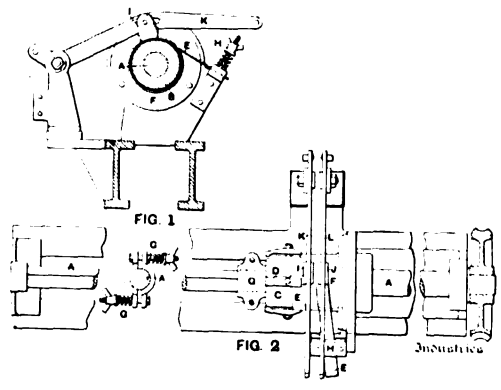

FIG. 1

FIG. 2

to the effective width of the strip when welded. This guide F acts as a fence whereby the strip is guided on to the mandrel. This spiral fence or guide is formed of a short cylinder surrounding the mandrel and fixed to the headstock, but insulated therefrom. G is an adjustable spring clip embracing the mandrel and opposing by its friction sufficient resistance to the motion of the clip head C to cause the edges at the point of welding to be pressed together with the necessary force, as the strip is fed on against the helical fence guide F. H is an adjustable spring clip embracing the strip whereby the laying-on tension of the strip is regulated. I J are electrical contact pieces attached to adjustably loaded levers K L, pivoted side by side. The contacts I J bear respectively upon the convolution already wound on the mandrel, and on the strip being laid on, one at either side of the abutting edges at the point where the weld is to be effected. The levers K L are insulated from each other and respectively connected at any suitable points with the leads from the transformer. The porcelain collar B is secured by a screw-nut on the mandrel A and the collar B, clip head C, contact blocks I J, and guide fence F are removable for the purpose of being replaced by others corresponding to the diameter of the tube to be made. Instead of welding the edges together, they may, as above mentioned, be united by brazing, for which purpose a wire of suitable alloy is fed in along with the strip and between the edges of the convolutions so as to be fused between and unite the adjacent heated edges. The apparatus for making pipe bends is similar in construction and operation to that above described, except that the porcelain collar is curved to the arc of the intended bend, the welded pipe, as it is forced off, being received by a radial arm suitably centred. Claims: Spirally formed and electrically welded or brazed tubes, straight or curved, of copper, its alloys, and of aluminium; the machinery for making the same, as described.—No. 2901. February 22nd, 1890. 8*d.*

Pumping Engines.—*L. d'Auria & H. Robert, Philadelphia, U.S.A.*—This invention relates to the class of non-rotative direct-acting steam pumps, in which, particularly where steam is used expansively, the propelling force of the engine is, in the earlier part of the stroke somewhat greater, and in the latter part of the stroke somewhat less, than the total pressure exerted by the liquid column upon the pump plunger, and it is stated that the compensating devices generally employed in such cases practically nullify the accelerative work resulting from excess of steam pressure above the pressure of the water; this specification describes means whereby these engines may use steam expansively without the loss of this accelerative work, a kind of balance weight being provided, whose useful effect relatively to the moving parts of the pump is increased by giving it a proportionately greater speed, as will presently be seen. The vibrating arms usually employed to operate the steam valves are considerably extended, and are loaded at the end of their longer arms with weights, for the purpose of increasing the accelerated mean weight. The position of the weights upon the arms can be shifted, and as this shifting affects the value of the accelerated mean weight, it will affect also the piston speed, other things remaining the same. The arrangement is considered to be a controlling, as distinct from a compensating, device, and is claimed accordingly, and as described.—No. 2883. February 17th, 1891. 8*d.*

Governor and Safety Apparatus.—*W. M. Musgrave, Bolton.*—This invention is arranged to operate the valve-gear to shut off steam to prevent excessive speed, and, in the event of any derangement, to stop the engines. One modification of the apparatus is illustrated in the accompanying illustrations, Fig. 1 being a side elevation and Fig. 2 an end view. A spindle A mounted in bear-

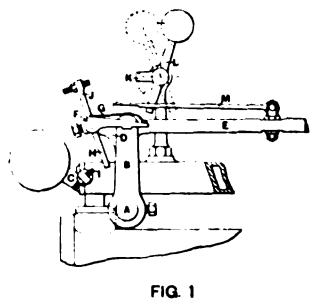

FIG. 1

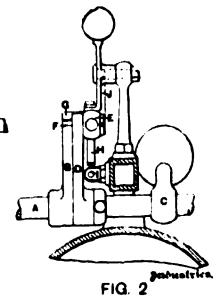

FIG. 2

ings on the cylinder or valve chest is connected by suitable means to the valve-gear, and has secured upon it two levers B and C, and loosely mounted upon it a lever D. This lever D is operated by a rod E (which is connected in the usual manner to the governor), and carries a catch piece F kept in position by a spring G which engages with a lever B. Should the speed of the engine cause the governor to rise to its highest position, the rod E causes the catch piece F to be disengaged by means of an arm H being brought into contact with the screw I, and the spindle A will be turned by the action of the falling weight on lever C, and so actuate the valve gear and stop the engine. If accident should cause the governor to reach its lowest position, the arm J makes contact with projection on lever L, and the catch piece F is disengaged and the engine stopped as before described. The lever L may be moved into the dotted position by the attendant to prevent the apparatus acting when engine is stopped in the usual way, but the lever L is returned by notched rod M upon restarting engine. Several other arrangements are described for carrying out this invention, and in one of them a spring is substituted for the lever L. Claims: The method of preventing excessive speed in motive power engines, and means for stopping same, consisting of a catch released from a lever or spindle working the valve-gear by levers or the like attached to said catch, and coming into contact with stops through the extreme rising or falling of the governor, together with automatic means for operating spindle and valve gear; also claims the various modifications described.—No. 2605. February 13th, 1891. 6*d.*

Drilling Machines.—*J. Claridge & R. Middleton, London.*—This invention relates to improvements in the Tyler and Ellis square hole drilling machine. In these improvements, instead of keeping the roller on the drilling spindle or its sleeve by means of two spiral springs, a second cam or template is substituted, struck to such dimensions that a line drawn through the centre of the spindle from the face of one cam or template to the face of the other shall always be of the same length; thus, a roller placed on the opposite side of the spindle to the point of contact of that used in the Tyler and Ellis machine will always remain in contact with the second cam or template, and maintain the contact of the first roller with its cam or template. The contact of the second roller, and through it of the first roller, is maintained in order to meet any small irregularities of the cams or templates. The arm which carries the second roller may be moved free from its template or cam when it is desired to bring the drill spindle vertical for drilling round holes. Another improvement consists in the employment of a sliding bracket for carrying the ball bearing of the spindle, which bearing, when moved by screw upon

Digitized by Google

the main head, varies the size of hole to be drilled. A solid spindle, with altered form of tool socket, is employed. The driving gear is placed at the ball bearing, so that the machine is driven at the nearest possible point to the work. An arrangement of index is described, operated by the adjusting mechanism of the tool, to indicate the dimensions of the hole about to be drilled. Claims: The use of the whole of the improvements described, which, to be properly appreciated, require that reference be made to the quoted patent of Messrs. Tyler and Ellis, No. 3850, A.D. 1890.—No. 20716. December 19th, 1890. 8*d*.

Gas Engines.—*H. T. Dawson, Salcombe, Devon.*—The engine described is a four-cycle motor in which the piston performs the operations which, in other engines, are regulated by a valve, this engine having a piston which, besides reciprocating, revolves once for each stroke of the engine. In the accompanying illustrations of the engine Fig. 1 is a side elevation, Fig. 2 a

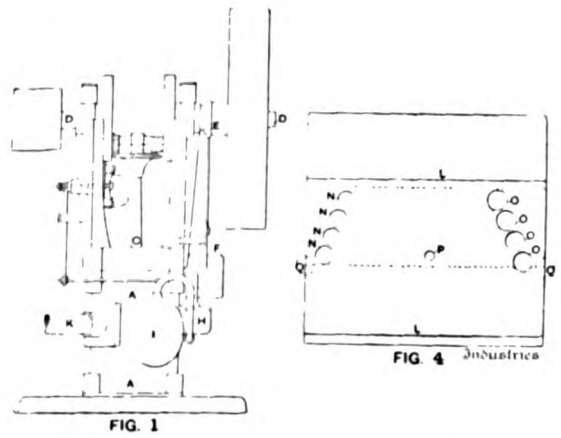

FIG. 1

FIG. 4

vertical section of the cylinder and piston, showing the connecting rod, crank pin, and some other parts, Fig. 3 is a horizontal section, and Fig. 4 will be referred to later. In these figures A is the cylinder, water-jacketed, and containing a piston B, which by a connecting rod C drives a crank on a shaft D; an eccentric E on this shaft actuates an air pump F, whose object is hereinafter explained, and an elastic bag receives the air from the pump. H is a casing containing a governor valve which opens for the admission of air and gas to the cylinder. An elastic bag I serves to maintain a uniform gas pressure. J is the ignition apparatus, and K the exhaust or outlet from the cylinder. The piston is tubular and about twice the length of the stroke, the piston tube L being closed by a diaphragm M situate at about a fourth of its length. The cylinder is about thrice as long as the stroke, and has long ports at about its centre part, which extend spirally in the cylinder walls for rather less than the length of the stroke. Fig. 4 shows, to a larger scale, the interior of the cylinder developed. The full circles show the ports or passages formed in it. The ports N in this figure serve for the admission of air and gas, and they all communicate with a passage formed partly in the walls of the cylinder and partly in the port cover, and form or run into one long port. They also communicate with the governor valve. The exhaust ports O are similarly arranged. P is the firing port. One modification of the arrangements for rotating the piston while it reciprocates may be readily understood from the illustrations. The piston has a port through its tubular part at about the centre of its length serving for all the purposes of admission, ignition, and exhaust. The relative position of this aperture is indicated by dotted lines in Fig. 4, and is marked Q; it is carried by the movement of the piston successively over the ports of the cylinder. In some cases the governor valve is so constructed as still to admit air when the gas passage is closed. This partially destroys the vacuum in the cylinder, which would otherwise be excessive, and arrangements are made whereby, although the governor may vary the quantity of the charge, its proportions of air and gas remain approximately

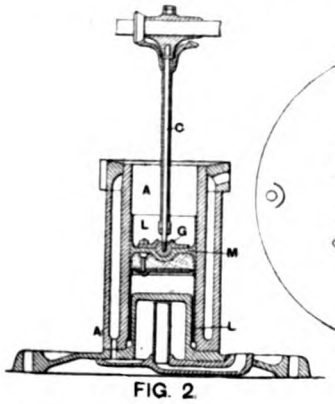

FIG. 2

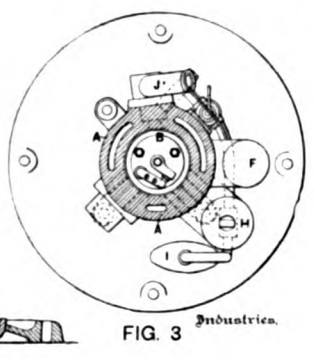

FIG. 3

constant. The ignition apparatus, in one of its forms, consists of a tube or capsule of metal or of porcelain contained in a furnace chamber to which a current of mixed gas and heated air is supplied, the air being forced in by the air pump F before referred to. The tube is gradually brought to and and kept at a state of high incandescence, and rapid ignition of the charge is said to result in consequence. The extra stages are sometimes adopted, by which a clearing charge of air is drawn in and expelled between the quadruple series of operations at first referred to. Claims: A four or six-cycle engine in which a reciprocating and rotating piston operates as a valve in the manner described; the governor and valve details varying the quantity of the charge, while the proportions of gas and air therein remain constant; the various modifications of ignition apparatus; also the various modes of imparting rotation to the reciprocating piston. Claims also the gas engine as a whole.—No. 6407. April 26th, 1890. 1*s*. 1*d*.

Apparatus for Burning Hydrocarbon Fuel.—*J. P. Swift, Woods Holl, Mass., U.S.A.*—This invention relates to apparatus for burning hydrocarbon oil, especially crude petroleum, as a fuel to supply heat for making steam, and for like purposes. Outside the steam generator, for example, is an initial combustion or ignition chamber, the bottom of which is preferably formed of a pan covered with asbestos, mineral wool, or similar substance. Oil is fed into this chamber by any suitable feed, and is ignited therein by any well-known means. Air to support combustion is admitted by an air opening provided with a damper for regulating purposes. The oil ignited and burning in this chamber gives off vapour or gas, which passes through an outlet of annular form on its way to the point where heating is required, and, to complete the combustion of the vapour or gas in the ignition chamber, an air pipe leads air from the exterior of the apparatus to the centre of the annulus, and beyond the outlet a second pipe is provided in which the vapours and air finally mix, and by which they are delivered to the furnace of the boiler or the like. The arrangement thus far described is defective in that there is a tendency to the formation of soot around the edges of the outlet pipe and along its walls. Its formation around the outlet edges is obviated by leading an additional air supply into the apparatus to mingle with the vapours at the beginning of the outlet pipe, and a third air supply may be led into the outlet pipe at some point along its length, for a similar purpose. Claims: The apparatus substantially as described in the first portion of the description, and the apparatus in detail, with the additional pipes for air supply arranged as described.—No. 6502. April 28th, 1690. 8*d*.

Guillotine Paper Cutters.—*H. Harrild, Jun., & J. F. Buckland, both of London.*—In the machines constructed according to this invention the improvements comprise a novel arrangement of the parts by which the up-and-down motion is given to the knife frame and to the clamping beam, with the object of doing away with the counterbalance weights hitherto employed in this class of machine to prevent the knife frame and beam descending of their own weight when the machine is disconnected from the driving power or the brake is applied. These improvements are embodied in the machine shown below, in which Fig. 1 is half of

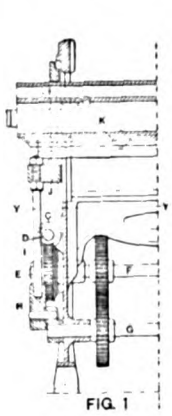

FIG. 1

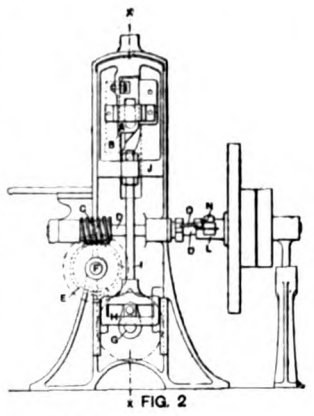

FIG. 2

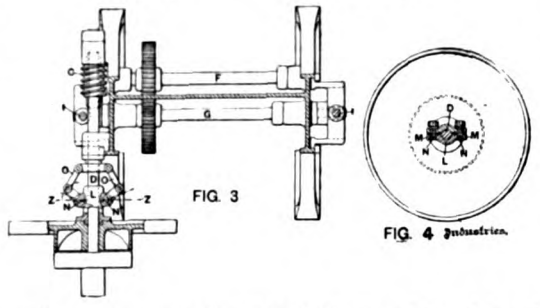

FIG. 3

FIG. 4

a vertical section on the line X X of Fig. 2, and Fig. 2 is a side elevation, Fig. 3 a horizontal section on the line Y Y of Fig. 1, and Fig. 4 a section on the line Z Z of Fig. 3. A is the knife frame and B the clamping beam. The up-and-down motion is given to the knife frame by the following means:—A worm C on the first motion shaft D drives a worm-wheel E carried by the shaft F, which, by spur gearing, rotates the crank-shaft G, the cranks of which, as the shaft revolves, give up-and-down motion to the slide blocks H, which move in vertical guides in the side frames of the machine. These slide blocks H are connected by rods I to upper slides J, which carry the knife frame A and the presser beam B, so that these receive the requisite up-and-down motion. The presser beam B moves in vertical guides, and the knife frame moves during the lower part of its travel in inclined guides K in the presser beam, so that by its slanting or oblique movement it acts upon the paper with a draw cut. The motion being communicated by worm gearing, the knife framing is prevented from descending by its own weight, and the usual counterbalance weights may be dispensed with. The arrangement of clutch mechanism consists of a split clutch L mounted on the fly-wheel shaft D, and having dowels or analogous devices to enter corresponding holes in the wheel so that the clutch and wheel shall rotate together. The clutch has flanges or lugs M, tapped to receive screw bolts N, which when given a slight turn bring the flanges towards each other, and thereby cause the clutch to grip the shaft D. When the shaft is thus gripped it turns the fly-wheel and clutch; when, on the other hand, the clutch is slacked, the fly-wheel and clutch turn loosely on the shaft. The screw bolts N are turned by toggle levers O, connecting them with a grooved sleeve on the shaft, which is operated as is customary. Claims: The paper cutting machine, and also the clutch mechanism, substantially as described.—No. 10253. July 2nd, 1890. 8*d*.

Compensating Mechanism for Signals.—*J. P. Annett, Southampton.*—This is an improved arrangement of mechanism for actuating signal wires in such a manner as to allow the wire to expand or contract according to variations of temperature, and the essence of the invention is that the wire is free to move according as it is acted upon by the temperature and is not in absolute connection with the lever until the lever is worked for the purpose of operating the signal. In the example given, a vertical rod is operated by the signal lever, and at the lower end of that rod is a pulley wheel. At about the normal level of this wheel and in line therewith is a second wheel centered in a fixed frame; secured to this frame, above the last-mentioned wheel, is a pawl pivoted at its centre and having a grooved portion bearing upon the single wire where it leaves the upper side of this pulley and passes below the pulley upon the vertical rod, going thence under another pulley closely adjoining, from which it passes to the signal. At the signal box end the wire terminates in a weight, which rises or falls with variations in the length of the wire, and keeps it at uniform tension, but which, of course, is insufficient alone to operate the signal. Upon the signalman wishing to operate the signal, he works his lever, which pulls the vertical rod and its wheel upwards; the wire being also pulled upwards, tilts the pawl, and one end thereof being thus raised the opposite end grips the wire and holds it stationary between the fixed pawl and the pulley; further motion of the vertical rod must therefore haul in the wire and cause its opposite end to work the signal. Upon the vertical rod being lowered, the wire is first slacked out, placing the signal at danger, and the pawl is next released, leaving the wire free, as at first. Claims: The compensator as described.—No. 8697. June 5th, 1890. 6*d*.

Resistance Governors.—*G. P. Spooner, Portmadoc, North Wales.*—The idea of the inventor is to use a spring clutch to connect the driving and driven shafts, and to arrange it so that when the power is being utilised the springs are compressed and

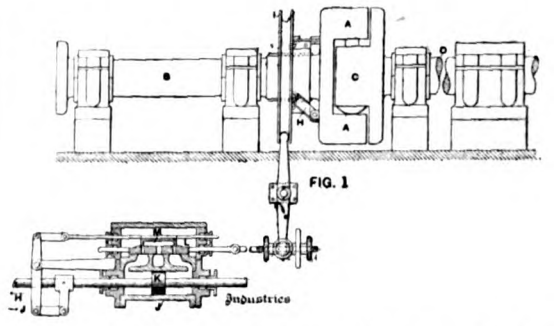

FIG. 1

steam is admitted to the cylinders without throttling. When the work is suddenly reduced or thrown off—for example, when in a marine engine the propeller rises out of the sea—a lever acts on the throttle-valve to govern the distribution of steam. The arrangement is illustrated in side elevation Fig. 1 as applied to a marine engine, Figs. 2 and 3 being views of details. A is a disc fast on the driving shaft B, and C is another disc fast on the propeller shaft D. Three studs E pass through the disc A, and three similar studs F pass through the disc C. These studs E and F terminate inside the discs in sockets, and have placed between each pair helical springs, Fig. 3. Attached to the studs E are levers H connected to a grooved pulley I, which is capable of longitudinal movement upon the shaft. While the resistance is normal the springs are compressed, but should any change take place in the resistance the wheel I is moved along the shaft, and so can operate any suitable governing device. The inventor describes an apparatus shown in Fig. 1, for governing the engine. A steam cylinder J is fitted with a piston K attached to a piston rod communicating with the throttle-valve. Two valves L and M are arranged as shown, one of which L is connected by means of a rod to a lever retained by the grooved pulley I, the other valve M being connected by means of a lever and rods to the piston rod, as may clearly be seen. The action is as follows:—When the wheel I is drawn along the shaft by the reduction of resistance the valve L is moved so that steam passes to one side of the piston K. This moves the piston K to operate the throttle-valve, and by this movement of the piston rod the valve M is moved and cuts off the steam from the cylinder J. Another modification is described for actuating the

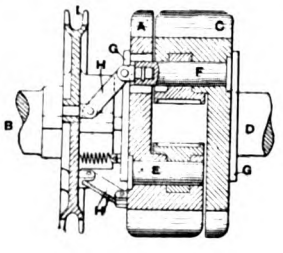

FIG. 2.

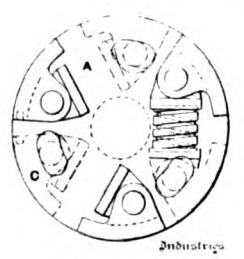

FIG 3.

grooved pulley by means of bell-cranked levers. The last arrangement described is where the grooved pulley is mounted on the propeller shaft, and the propeller shaft is capable of sliding longitudinally in its bearings. Helical springs are placed between the driving and propeller shafts. Claims: In apparatus for governing steam engines the utilisation of the variations in the load by means of springs to operate the throttle-valve; and the various arrangement described in the specification, including attaching pulley to propeller shaft.—No. 19852. December 5th, 1890. 8*d*.

Slide Valves.—*T. Townson, Stoke-on-Trent.*—The object of this invention is to obtain very short and direct steam and exhaust ports, and thus to diminish clearance. This is effected by forming the cylinder covers as a valve chest or casing, and adapting a slide valve to work across port faces at right angles to the axis of the cylinder. The cylinder covers are furnished with valve covers to allow the working faces to be planed and scraped, and to permit of the valves being placed in position. The valve stems are carried through the side of the covers, and are actuated by a secondary shaft, which is driven from the main shaft by suitable toothed gearing. It is preferred to make

Digitized by Google

the steam and exhaust passages separate from one another to avoid the cooling action of the exhaust steam. Expansion slides on the back of the main slides may be employed if desired. In one construction of slide valve the valve has two faces, one being the face controlling the admission and exhaust of the steam, and the other face, at right angles therewith, forming a surface which moves in contact with a bearing surface arranged to support the weight of the valve, which is kept up to its work by steam pressure. A port in one face communicates with the cylinder, and a port in the other face with the exhaust. The exhaust port is placed so as to be as near as possible to the exhaust outlet, the length of both steam and exhaust ports being determined by the thickness of the metal of the cylinder ends. At the stuffing-box end of the cylinder the valve is partially divided, so as to pass the exterior of the piston-rod stuffing-box. Claims: Arranging the valves to work on the cylinder ends; the valve with faces at right angles as described; the whole of the arrangements described and illustrated in the specification.—No. 8209. May 27th, 1890. 8*d*.

Steam Boilers.—*P. Kosinski & V. Kisielnicki, Warschau, Russia.*—This apparatus for the generation of high-pressure steam consists of two concentric cylinders, the bottoms of which are made hemispherical in form, the cylinders being let one into the other, leaving an annular space between the two. Between the two cylinders a flat helix is placed, so as to form a helical channel in which the water lies, and around them is an annular cylindrical casing containing at its lower part the grate. The products of combustion are led from a grate below the outer cylinder, around the cylinder passing over its upper edge and down an annular passage adjacent to the inner wall of the inner cylinder, finally ascending to the exit by a central flue. Water is periodically injected into the lower portion of the water space, and ascending the helix is converted into very high pressure steam, highly superheated, which by suitable connections may be withdrawn from the upper part of the steam space. Claims: The boiler for generating steam of exceptional pressure, arranged as described.—No. 4461. March 12th, 1891. 6*d*.

Hot Air for Furnaces.—*N. S. Hawks, Forest Gate, Essex.*—The leading principle of this invention is that air should be forced into easily removable chambers in the uptake or smoke-box of a boiler, that it should be heated in those chambers, and led afterwards into closed ashpits to support combustion. The heating chambers, in one modification adapted for marine use, consist of casings, one to each furnace, placed in the uptake over the ends of the tubes and fitted with short tubes passing through the chambers from front to back and forming extensions to the main boiler tubes, the chambers being either hinged to the boiler by horizontal or by vertical hinges, or being fitted to travel on rollers running upon horizontal guides, so that the ordinary boiler tubes may easily be got at. The air is forced into the chambers by a centrifugal fan, and is circulated between the short tubes by guide or baffle plates, being afterwards led to the ashpits or elsewhere as desired. Where the chambers are caused to travel horizontally, pins upon their sides "take" into inclined slots made in vertical angle irons secured to the tube-plate; this ensures that the chambers shall take a good bearing against the tube plates. They are lifted out of engagement with the slots by screw shackles, borne by the rollers upon which the chambers are supported. In lieu of the heating chambers of the type described, a smoke chamber may be arranged so that its hollow walls fitted upon the tube plate surround the ends of a group of boiler tubes; one side, or the front, of this chamber has a perforated plate, which impedes the exit of gases from the boiler tubes, and this perforated plate can at any time be turned upon hinges for purposes of regulation or to enable the tube ends to be got at. There are no special heating tubes in this modification, the air to be heated being led around within the hollow walls of the chamber, which may be corrugated or provided with internal and external gills, to baffle the air being heated and to add to the heating surface. This last example is shown as fitted to a locomotive, the air inlet pipe being trumpet-mouthed, to receive the indraught resulting from the motion of the locomotive. Claims: The heating chambers as described, hinged; the same, arranged to travel on rollers; and the chamber with perforated front to retain, normally, a considerable proportion of the gases, and being otherwise constructed as described.—No. 6647. April 30th, 1890. 11*d*.

Travelling Cranes.—*J. Platt, Royton, Lancaster.*—The improvements described are applicable either to hand or power cranes, and their object is that the three motions of hoisting, lowering, and traversing may be accomplished by one operating rope or chain, if the crane be worked from below, or by one and the same handle shaft if worked overhead. The rope pulley for hoisting is arranged as is usual, and a small pinion sliding on a shaft can be put into or out of gear with the hoisting pulley, and when put into gear causes a pair of drums, one at each end of the traveller, to rotate at equal speeds. The load hangs in the bight of a chain whose opposite ends are connected to the two drums, and when these two drums are operated as aforesaid at equal speeds, the load is neither hoisted nor lowered, but is traversed transversely to the right or left in accordance with the direction of motion of the hoisting shaft by which the two drums are thus operated. But the pinion referred to above may be drawn out of gear with the hoisting pulley, and brought against a fixed stop, which prevents it and one of the drums from revolving, whereupon, if the hoisting pulley be operated, the load will not be traversed, but will be raised or lowered as the case may be. Separate transverse travelling gear is avoided, longitudinal traverse being obtained as is customary, the operations of raising, lowering, and transverse traversing being governed by one rope. Claims: Substantially, the arrangement described, and operating as in the last paragraph.—No. 9480. June 19th, 1890. 6*d*.

ELECTRICITY.

Electric Batteries.—*H. H. Lake, London.* (*W. Dowse, Boston, Mass., U.S.A.*)—In this battery, by the peculiar arrangement of the solutions with reference to the elements of the battery, local action is said to be entirely obviated, and, there being no chemical action except when circuit is closed, it becomes unnecessary to amalgamate the zincs employed. The example shown is a quadruple cell, there being four porous cups within an outer vessel. These cups contain the zinc elements, preferably made cruciform to expose considerable surface to the liquid within the cup, and the elements are connected together by a ring secured to the tops thereof. The copper element is bent around the porous cups, the ends of the plate not meeting. In the bath for the positive elements chromic acid is employed, or any solution of a chromate or bichromate. The copper plate has for a bath sulphate of copper. A mixture of sal ammoniac, chromic acid, bisulphate of mercury, and chromic acid is preferred for the zinc bath. A solution of copper sulphate is poured directly into the outer vessel, a perforated feed cup containing copper crystals being immersed therein. Claims: The chromate, bichromate, or chromic acid bath for one element, in combination with a sulphate of copper bath for the opposite element; also the variations thereof, and the form and arrangement of battery described.—No. 3589. February 27th, 1891. 6*d*.

Electric Railways.—*A. M. Clark, London.* (*The Waddell-Entz Electric Co., Brooklyn, N.Y., U.S.A.*)—This is claimed to be a new system of electric transportation, consisting mainly in the employment in such a system of a continuous armature, which armature is stationary, and extends from end to end of the track to be traversed by the vehicle. This armature exercises its force upon a field magnet, which is carried by the vehicle to be propelled, with the aid of brushes or analogous contact devices that travel with the vehicle and convey the current from mains or conductors to that portion of the armature which is under the influence of the field magnet. One advantage claimed for this system is that the power applied is in the nature of a direct pull, and does not depend upon the weight of the car for its tractive force. Another advantage claimed is that the armature winding can be regulated to suit the traffic as regards speed and power required along different portions of the route. Thus, on an ascent, the windings may be closer than on a level. All conductors carrying dangerous currents are completely sealed in conduits which admit of no mechanical or electrical communication between the said conductors and the street or vehicle, and which prevents leakage, due to moisture or otherwise, and permits of the use of higher potentials than would otherwise be possible and consequently induces higher efficiency. Referring now to one form in which this invention may be employed, which is represented in Figs. 1 and 2 of the illustrations, A shows the armature placed in a conduit B below the level of the street C. The armature is a continuous coil extending from end to end of the track. D is the field magnet suspended within the conduit

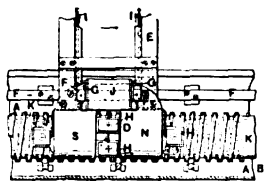

FIG. 1.

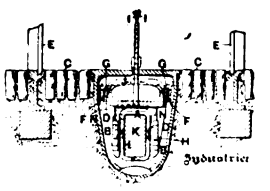

FIG. 2.

B from the vehicle E, and which embraces the armature A. F F are the mains or conductors, which are secured within the conduit B, and extend from end to end of the road. G G are contact pieces carried by the magnet D, and bearing against the mains or conductors F F. H H are the brushes which are carried by the field magnet D, and bear upon the outside of the coiled armature A. The magnet D is excited with the aid of conductors I I that lead from the car or vehicle E to and around the spool J of the magnet D. The winding of the armature A is that of a continuous coil upon an iron core, and corresponds to a Gramme ring armature cut at one place and laid out straight. In another modification the parts as represented in Figs. 1 and 2 are substantially duplicated, with the exception that instead of the continous core K a travelling core is represented, this travelling core being only about as long as the field magnet D, and, in fact, of sufficient length only to complete the magnetic circuit between the two magnet poles. Claims: Various modifications of the apparatus described in the specification, and consisting substantially of a stationary armature in combination with a movable magnet, the latter carried by the vehicle, together with the various accessories necessary to enable the magnet on the vehicle to be influenced by the current in the armature windings, and so effect the movement of the vehicle.—No. 4758. March 17th, 1891. 8*d*.

CHEMISTRY.

Bicarbonate of Soda.—*J. Vivian, St. Bees, Cumberland, & G. Bell, Wavertree, Lancaster.*—This invention refers to apparatus used in the manufacture of bicarbonate of soda. The apparatus comprises two or more carbonators arranged one above the other, and each provided with a perforated valve adapted to act as a gas and blow-off cock, the said carbonators having formed around them a jacket or jackets, within which brine on its upward course, preparatory to its treatment in the carbonators, is caused to circulate for the purpose of cooling the contents of the said carbonators and of receiving any ammonia that may leak therefrom. Between the carbonators is a cooling apparatus in which carbonic acid is cooled as it flows from one carbonator to another. An arrangement of apparatus according to this invention with three carbonators is shown in the accompanying illustrations, in which Fig. 1 is a vertical section of the upper portion of the apparatus, and Fig. 2 is a vertical section of the lower portion, these two portions when in use being arranged one above the other. The apparatus and the mode of operating the same may be described as follows:—A B and C are the carbonators which are charged from the saturator (which comprises an outer cylindrical casing D with an inner cylindrical vessel E) with brine saturated with ammonia gas. Carbonic acid gas is then forced by an engine through the pipe F and perforated valve G, and into the carbonator A, rising through the liquor therein. The carbonic acid gas arriving in the upper end of this carbonator flows through pipe H into a lower cooling apparatus, passing upward through the tubes I thereof, and downwards through the tubes J. It then flows through the pipe K and perforated valve L into the carbonator B, rising through the liquor therein to the top thereof, whence it passes through pipe M into the upper cooling apparatus, flowing through the tubes I and J thereof and the pipe N to the

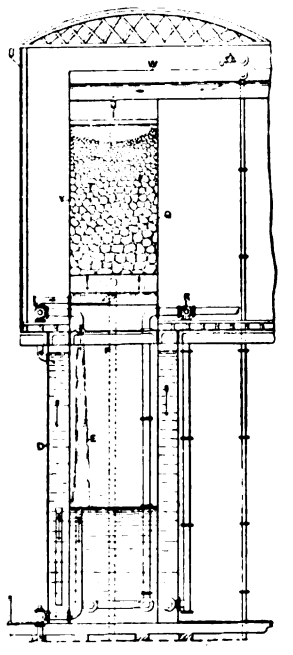

FIG. 1

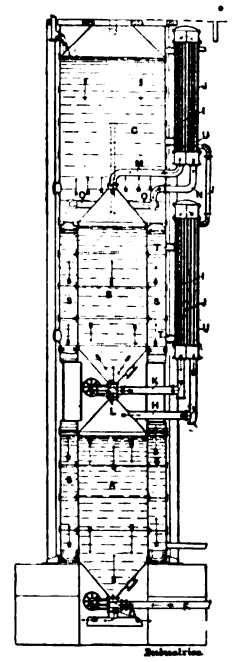

FIG. 2.

perforated pipe O by which it is distributed through the liquor in the carbonator C. The gas not absorbed in this carbonator passes through pipe P into the tower Q, through which it rises, meeting the descending brine, which absorbs any ammonia that may be present in the escaping gas. Any gas not absorbed escapes by the outlet R, and may be further dealt with if necessary. Whilst carbonic acid is passing through the carbonators in the direction of the arrows shown in full lines, and converting the saturated brine therein into bicarbonate of soda, brine is forced into the annular space S between the carbonators A B and the outer casing, circulating upward through the said space and cooling the contents of the two carbonators. The brine then flows through the two branches T into the casing U of the lower cooler, and through pipe V into the casing of the upper one, whence it passes to the brine cistern W. From this cistern it descends into and percolates through coke X with which the tower is packed, going thence to the saturator, where it is treated with ammonia gas supplied from any suitable still. After the brine has been sufficiently treated in the saturator it is taken in succession through the carbonators C B and A, its conversion being completed in the latter. By cooling the contents of the carbonators the yield is increased. Claims: In apparatus for the manufacture of bicarbonate of soda by the ammonia soda process, the arrangement of two carbonators one above another, and each provided with hollow perforated valves such as G and L adapted to act alternately as gas and blow-off cocks, so that gas can be distributed to the contents of the carbonator above them, and the contents of said carbonator can be run off when desired; cooling the carbonators, and the general combination for the purpose described.—No. 7527. May 14th, 1890. 8*d*.

MISCELLANEOUS.

Stockless Anchor.—*F. J. Sinnette, Southampton.*—The improved stockless anchor described in this specification is composed of two principal parts, specially proportioned and arranged so as to transmit the stresses from the arms to the shank without depending upon the strength of the bolt connection as is usual. The shank passes into the tripping head, which is slotted to receive it, the portion of the shank just above the tripping head being enlarged, and the tripping head being provided with projections on its upper side, on each side of the slot and in line with the shank of the anchor. The tripping head and arms or flukes constitute one member of the anchor, and the shank the other, the two being connected by a bolt, which, however, works in an elongated hole and acts merely as a connecting link to keep the parts in proper relative position. When the anchor takes the ground the arms and tripping head oscillate over to one side, and the projections on the tripping head thrust against the enlargement of the shank and the stress is directly transmitted from one part to the other by contact, and the bolt connection has no tendency to shear as is commonly the case. Claims: A stockless anchor with tripping head which surrounds the lower end of the shank, both shank and tripping head being provided with enlargements forming bearing surfaces for the purpose described.—No. 8194. May 27th, 1890. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

THE GARRUCHA AERIAL ROPEWAY.

In our issue of the 30th January last we gave extracts from the Foreign Office Report on the iron ore mines in the district of Garrucha, in the South of Spain. Reference is there made to an aerial ropeway employed for conveying the ore from the mines near the village of Serena to the shore of the Mediterranean, for shipment at Garrucha. As this ropeway is, we believe, the most important aerial line that has yet been constructed, a description of it will no doubt be of interest to our readers, and by the courtesy of Messrs. Commans & Co., of 52, Gracechurch Street, London, E.C., who are the representatives for this system of ropeway in this country, we are now enabled to give full particulars of this interesting line.

The chief feature of this—the Otto—system of rope transport is the employment of *two fixed carrying ropes*, along which the buckets are hauled by a light endless running rope. The advantages of using fixed ropes are, that it is possible to carry heavy loads, cross large spans, and surmount the steepest gradients with safety. Without this system of transport these rich mines would

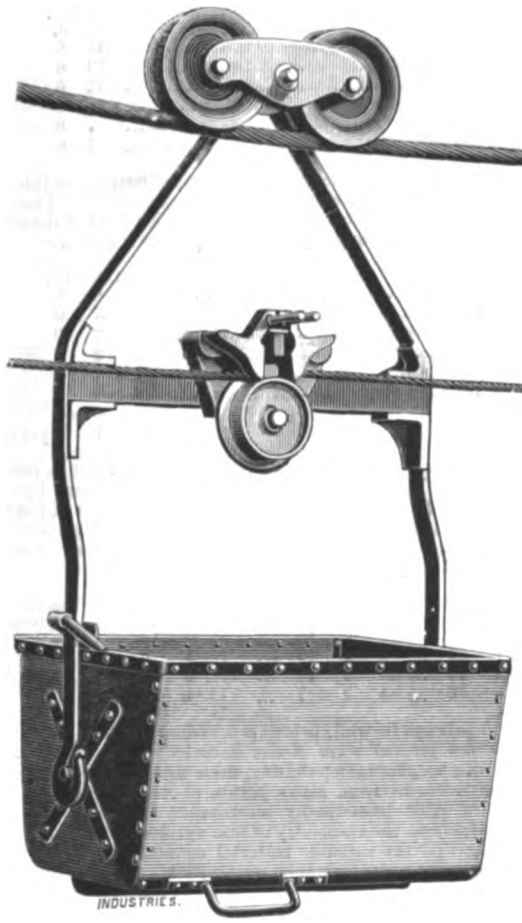

Fig. 1.

probably not have been opened out, as the cost of an ordinary railway would have been very great, and more than absorbed all prospective profit on the sale of the ore.

The standards for these lines are made either of wood or iron, and, according to their height and the strain they have to withstand, are either two or four legged. Figs. 2 and 3 show the design of a four-legged wooden support seen in perspective in the view (Fig. 6, on page 578) of the line, and which is 85ft. in height. Fig. 6 also shows a perspective view of the largest span on the line (918ft.), situated near the Villa Reforma. At this point no less than six empty and six full buckets are suspended at one time between the supports. One of the standards on this line has a total height of 118ft. The two-legged supports are held in position with guy rods. Figs. 1 shows clearly the relative positions of the fixed and hauling ropes, and Fig. 2 shows how the carriers pass the supports.

These carriers consist mainly of four parts—a truck or runner, a triangular-shaped hanger, the bucket or skip, and the grip for attaching the carrier to the hauling rope. The form of buckets depends largely on the nature of the material to be transported; for ore, coal, &c., a bucket arranged to be tipped by hand is usually employed, as illustrated in Fig. 1. The buckets used on the Garrucha Line are of this form, and have a capacity of 7 cwt.

A most important detail, to ensure regular and uninterrupted working of a line, is the form of grip that is adopted for attaching the buckets to the hauling rope.

THE GARRUCHA AERIAL ROPEWAY.

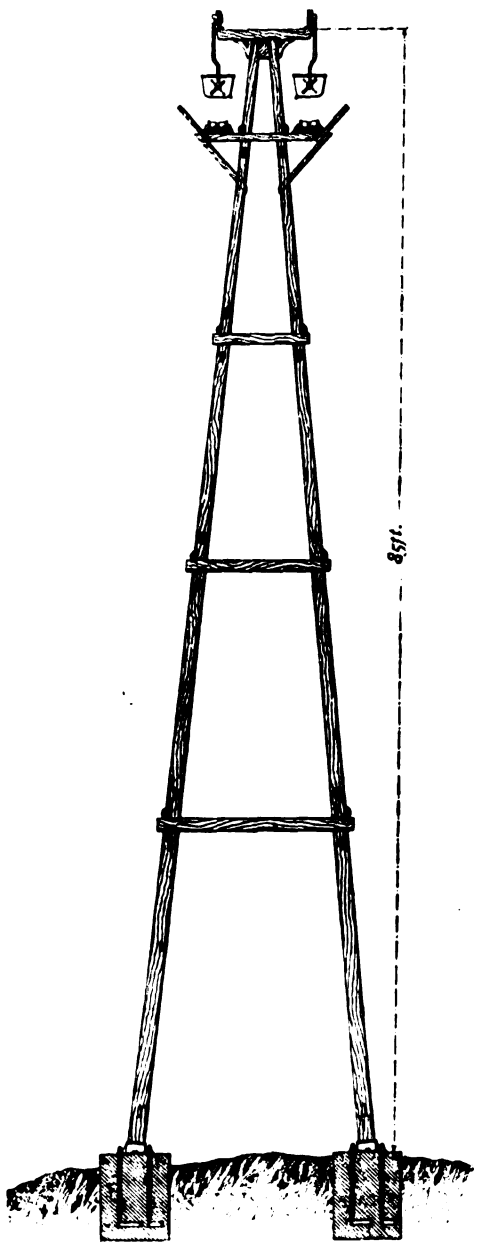

Fig. 2.

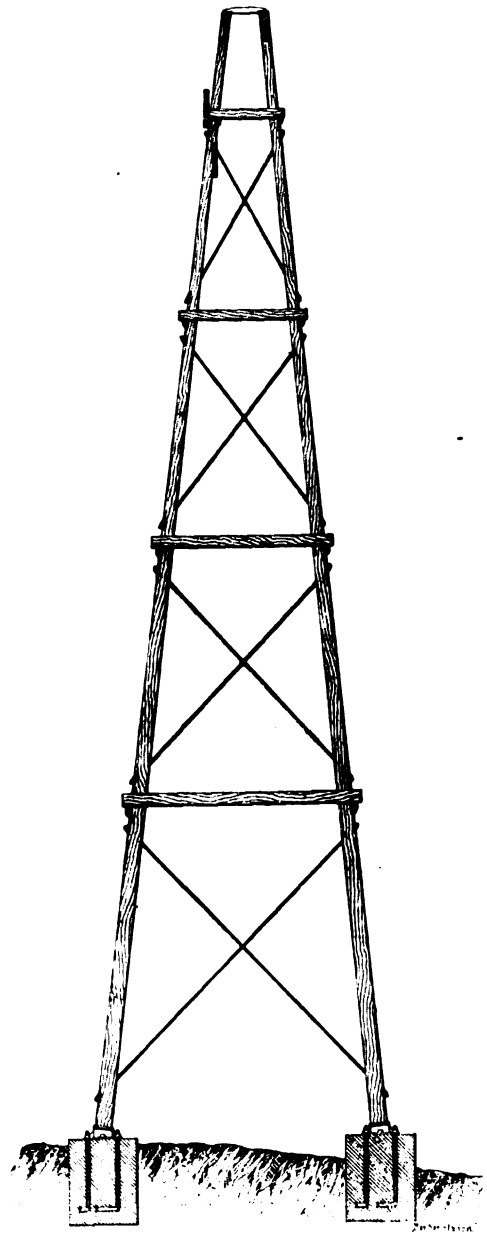

Fig. 3.

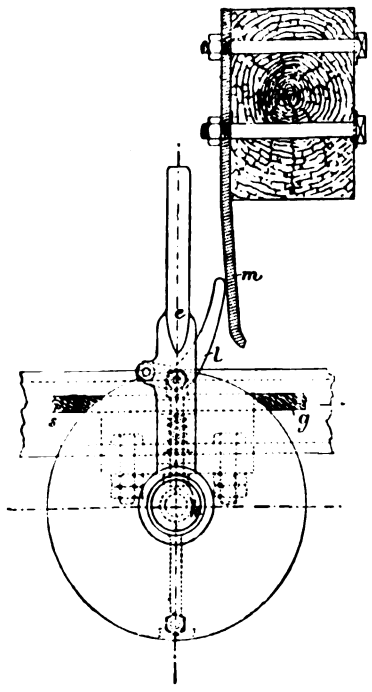

Fig. 4.

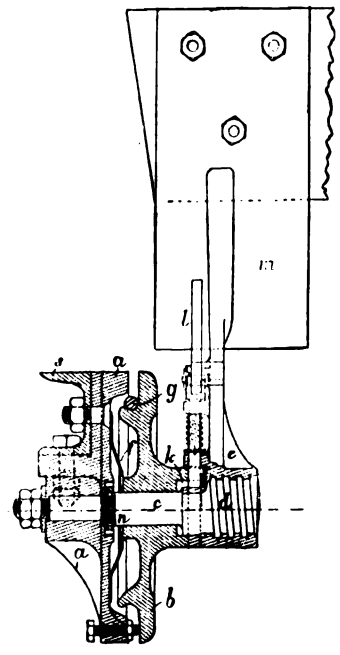

Fig. 5.

For lines with easy gradients friction grips are employed; these are of two kinds—the first, used for gradients up to 1 in 6, is shown in elevation and section in Figs. 4 and 5, and consists of two smooth-faced discs *a* and *b*, one rigidly attached to the cross-bar of the hanger, the other being free when out of action to revolve and act as a guide and supporting roller for the hauling rope. The spindle carrying the movable disc has a square thread on its outer end, and carries a lever, the boss of which forms the nut. If the lever is

Digitized by Google

THE GARRUCHA AERIAL ROPEWAY.

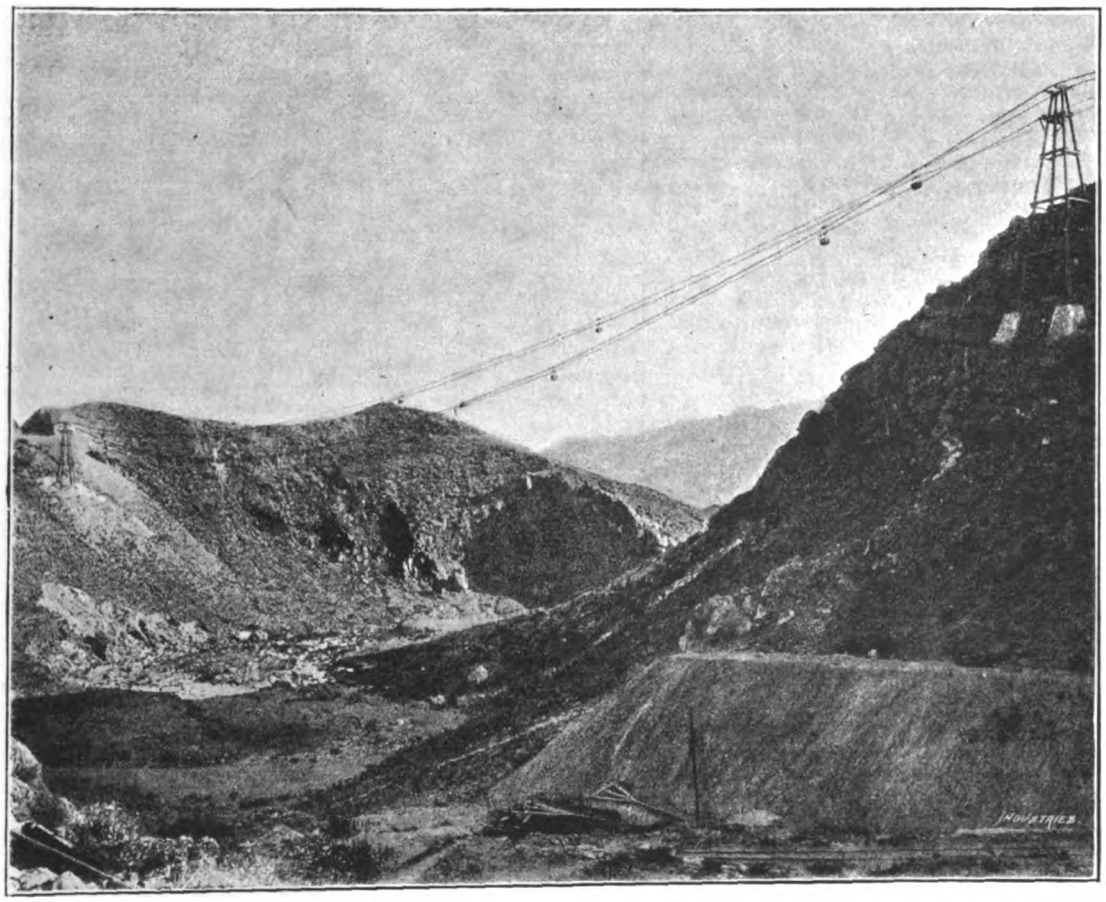

Fig. 6.—918ft. Span near Villa Reforma.

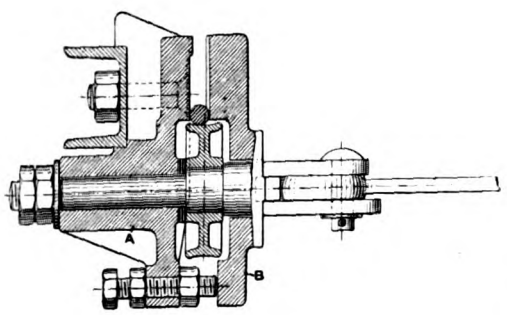

Fig. 7.

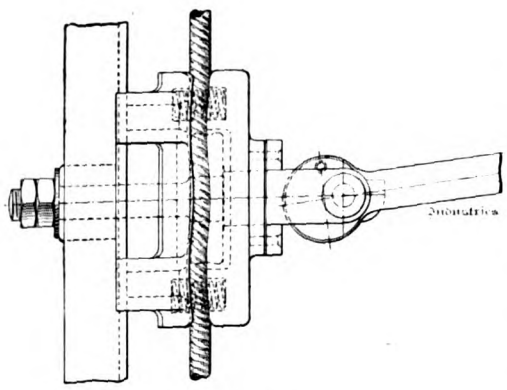

Fig. 8.

hanging down the discs do not grip the rope, and are kept apart by a spring. On raising the lever, however, through an angle of 180° the discs are made to approach each other, and the hauling rope is tightly gripped between them. The lever is prevented from falling in transit by a small spring trigger. For gradients from 1 in 6 up to 1 in 3 a friction grip with corrugated jaws A B (Figs. 7 and 8) has recently been employed, which differs from the disc friction grip above described, in that the movable plate or jaw B is corrugated and does not revolve, the pressure being obtained by means of a lever and eccentric, as clearly shown in the illustration. Both forms of grip work exceedingly well, and permit of the buckets being attached at any point of the hauling rope.

As on the Garrucha Line there are gradients of 1 in 2½, a friction grip would not be sufficiently reliable; it is necessary, therefore, to employ the "pawl" grip, shown in Figs. 9, 10, and 11, on page 579, representing a front elevation, end sectional elevation, and general plan respectively. This consists of two symmetrically placed pawls C C, free to move in a vertical plane, with forked ends, which drop down on either side of the knots attached at intervals to the hauling rope. The hauling rope itself is carried on a roller D slightly below the pawls. To throw the pawls in and out of gear pins are attached to their upper ends, and these at the stations come in contact with guide rails, which raise the pawls, automatically releasing the hauling rope and permitting of the carrier being switched off on to the shunt rails at the station. A large number of these grips, we are informed, are now at work, and in no instance have they been known to fail.

The latest and best form of knot, shown in Figs. 12 and 13, has a star section, and has an outside diameter slightly in excess of that of the hauling rope. The strands of the hauling rope lie in the helical grooves as shown, the ribs forming the star projecting sufficiently above these to form a shoulder to press against the pawls of the carrier coupling. The knot is made fast to a steel wire strand E about 6ft. long, which takes the place of the hempen core in the hauling rope; by this means it is rigidly held, and any strain distributed, the strand forming the core being tightly gripped throughout its length by the strands of the hauling rope itself. The advantages of this form of knot are that it can be quickly attached to, and—when worn—removed from, the hauling rope without cutting the same; for fixing it is not necessary to employ white metal, which was found to very much impair the strength of the rope; moreover, the hauling rope does not lose its flexibility at the point of attachment, and any breakage of single wires is at once visible and easily repaired.

(To be continued.)

ECONOMICAL PUDDLING AND PUDDLING CINDER.*

(Concluded from page 556.)

I do not propose to do more than incidentally touch upon the composition of the finished metal, and the rest of this paper will, therefore, be devoted to a brief consideration of the character and composition of the fettling used and the cinder produced. It may, perhaps, in this connection, be of interest to some members to have on record a few details illustrating the practice of one of the oldest and best known firms in the South Staffordshire iron trade. For these figures I am indebted to the kindness of Mr. A. E. Barrows, who for some time past has worked in the Metallurgical Laboratory of the Mason College, and who is connected with the firm of William Barrows & Sons, of Bloomfield, Tipton. It will be remembered that it was at these works that the modern or "boiling" process of puddling was first introduced, more than half a century ago, by the late Joseph Hall, one of the early members of the firm, and the excellence of the iron made by this firm has been referred to by several metallurgical writers, including the late Dr. Percy, while their brand of B. B. H. is of world-wide reputation. The iron used will, of course, vary with the class of work in hand, but consists of a mixture of about four brands of all-mine pig iron; such a mixture would contain about 0·55 per cent. of phosphorus. The weight charged is 4 cwt. 1 qr. 18lb. The varieties of fettling used, together with the prices delivered at the works in March last, are as follows:—

	Per Ton. s.	d.
Best tap	17	6
Ore (purple)	13	6
Bull-dog	12	6
Do. ground	15	0
Roll scale	7	0
Hammer slag	1	0

Calcined pottery mine is also an important fettling in this district, but so far as I am aware hematite is not used. The consumption of fettling, as calculated over a week's work of the above iron, was, per ton, averaging 25 cwt. 2 qrs., as follows:—

	Cwt.	Qrs.	Lb.
Best tap	3	0	0
Ore	0	3	0
Bull-dog	2	2	0
Do. ground	1	2	0
Scale	1	1	0
Hammer slag	4	0	0
	13	0	0 per turn.

Or nearly 10¼ cwt. of fettling per ton of pig. It must be remembered that this is for best iron, and is more than is used by ordinary makers. The following figures give the weight of pig iron charged, the puddled bar obtained, and the cinder produced in three ordinary heats as above, the weights being taken for me for experimental purposes:—

Weight Charged. Cwt.	Qrs.	Lb.	Yield. Cwt.	Qrs.	Lb.	Tap Cinder Boilings. Cwt.	Qrs.	Lb.	Tap Cinder Tappings. Cwt.	Qrs.	Lb.
4	1	18	4	2	14	1	1	0	1	1	0
4	1	18	4	2	14	1	0	0	1	1	12
4	1	18	4	2	7	1	0	20	1	2	0

It will perhaps be well, before proceeding further, to indicate what is the present state of our knowledge in relation to the removal of phosphorus in puddling, since this is probably the most important element from many points of view. So far as I am aware, the most trustworthy information is contained in Mr. Stead's papers on the chemistry of iron purification, and to me it is surprising that the valuable material contained in these papers has not met with greater public recognition. The correctness of Mr. Stead's conclusions has since been practically confirmed by Messrs. Harbord and Tucker. Briefly stated, the facts are as follow:—Under ordinary conditions of puddling, with a sufficiency of cinder and a fairly high temperature, a large proportion of the phosphorus is oxidised during the melting down of the pig iron, so that the melted metal frequently contains less than half of the phosphorus originally present. Phosphorus is further eliminated during the quiet period which precedes the boil, so that at the beginning of the boil the metal frequently retains not above one-fourth of the original amount of phosphorus. When the metal once becomes granular, or comes to nature, phosphorus elimination almost entirely ceases. The presence of silicon in excess retards phosphorus elimination; manganese acts in the same way when present in excess, but when part of the manganese has been removed, and the two elements are present in about equal proportions, they are rapidly removed together, and yield a very pure product. Oxide of manganese added to the slag does not appear to act like manganese in the pig, but the presence of an impure cinder at the latter part of the process may cause phosphorus to be once more reduced, and to pass back again into the iron. In short, the reactions in the puddling furnace closely resemble those of the basic Siemens process, which, of course, is what might be expected, since the fettling used is basic, and in each case the iron is melted in the furnace itself. Prior to Mr. Stead's researches, it was apparently the custom to regard the puddling and Bessemer processes as closely related, and that this erroneous view in part survives is shown by references I have given in the earlier portion of this paper. In the Bessemer process the metal is melted in a separate furnace, and the result is that the reactions of the acid and basic-lined converters not only differ from each other, but also differ from those of the puddling furnace. In the basic Siemens furnace, on the other hand, melting is performed in the furnace itself, and during the melting down, in a bath of rich cinder, it is quite possible, as Mr. Harbord has shown, to almost entirely remove the phosphorus originally present in the pig. It is also possible in the puddling furnace, with pigs which do not contain too much silicon or manganese, and with suitable fettling, to remove almost the whole of the phosphorus during the melting-down

* Paper read by Mr. Thomas Turner, Lecturer on Metallurgy, Mason College, Birmingham, before the Iron and Steel Institute, on the 7th ult.

Digitized by Google

stage. In the puddling process, since the removal of phosphorus almost ceases when the iron is no longer fluid, a high temperature during the boil, and particularly in the early part of the boil before the damper is put down, assists in the complete purification of the iron, by keeping the metal longer in the fluid condition, and promoting the action of the cinder.

As it is necessary, before discussing the relative economy of various kinds of fettling and cinder, to have some definite view as to the constitution of puddling cinder itself, I will here venture to put forth my own views on this matter. In the earlier portion of this paper I have referred to the unsatisfactory manner in which fettling is often referred to as oxide of iron, while, as a matter of fact, ferric oxide (Fe_2O_3) alone is not a satisfactory fettling on account of its infusibility. In skilful puddling, the cinder plays a most important part, not only during the middle and end of the operation, but also during the melting-down stage itself; and it is a bad workman who, during the earlier part of his heat, has to make cinder either by the oxidation of his iron or by melting down his side or bottom fettling. In other words, there should be a sufficiency of fluid cinder present in the furnace to cover, and thus to clear, the iron as it melts. Having thus a bath of fluid cinder to begin with, the workman has then to rely upon his less fusible fettling, and partly upon atmospheric oxidation, to supply the ferric oxide he needs during the process.

Magnetic oxide of iron is produced when iron burns in air or oxygen, and is usually represented by the formula Fe_3O_4 (or FeO, Fe_2O_3), though there are considerable differences in the proportion of ferrous and ferric oxide found in various samples of native magnetite and in the artificial "best tap." This magnetic oxide is fusible, as is evidenced by the fluid cinder on an "oxide bottom," sometimes used in reheating furnaces when "best tap" is made. But though magnetic oxide is fusible, it does not melt nearly so readily as ordinary puddling cinder. Ferrous silicates, such as FeO, SiO_2, or $2FeO,SiO_2$, are readily fusible, but have little oxidising power, and the iron they contain is not easily reduced by the action of carbon or other reducing agents. Good tap cinder, if carefully crushed and freed by a moderately powerful magnet from any shots or globules of iron, is found to be almost wholly attracted by a powerful magnet, thus showing the presence of a considerable proportion of magnetic oxide of iron. In connection with some experiments of this kind, it struck me that as a small part of the crushed cinder is not attracted by a magnet, it might be possible in this way to separate the phosphorus or other impurities, and to obtain a fertiliser on the one hand and best tap on the other from puddling cinder. I therefore repeatedly treated a sample of such cinder with a powerful magnet, until a portion was obtained which was not attracted, while the whole of the rest, about 85 per cent. of the original, was attracted. On analysis the following results were obtained:—

	Original Sample.		Portion not Attracted.
Silica (SiO_2)	17·12	...	18·06
Phosphoric anhydride (P_2O_5)..	7·62	...	7·22

From this I conclude that no further separation of the sort I had in view was possible, and that the part attracted was merely richer in magnetic oxide of iron, while the part not attracted was richer in ferrous silicate.

These and similar considerations lead me to put forward the following suggestions. Puddling cinder may be regarded as being essentially composed of two substances—ferrous silicate and magnetic oxide of iron. The first of these is readily fusible, comparatively neutral so far as its influence on the constituents of the iron is concerned, and cheap. It can be obtained at an almost nominal cost in the form of hammer-slag, which still retains in addition a very appreciable and useful quantity of magnetic oxide. Magnetic oxide itself, on the other hand, is less fusible, and with much ferric oxide is extremely refractory. It is an active oxidising agent, and is the chief constituent of the best tap, bull-dog, &c.; for it is erroneous to suppose that these materials consist of ferric oxide alone. During the puddling process, the more readily fusible silicate melts first, and then dissolves the magnetic oxide, or the still more refractory ferric oxide, which when dissolved forms magnetic oxide; and thus puddling cinder may be regarded as a solution of magnetic oxide, that is, of ferrous and ferric oxides, in ferrous silicate. Or, to put it in another way, just as the galvaniser uses hydrochloric acid dissolved in water to clean his sheets before coating them with zinc, so the puddler uses magnetic oxide of iron dissolved in a nearly neutral cinder to remove the impurities of his crude iron.

If the explanation thus given be the true one for puddling cinder, it is doubtless to a large degree applicable to other processes where oxides of iron are used as oxidising agents, such, for instance, as the old-fashioned refinery, the American bloomery, the Swedish and Styrian processes for producing iron or steel in an open-hearth, and the "washing" processes introduced by Bell and Krupp. In all of these cases the slag obtained is silicious and fusible, and contains a variable amount of dissolved magnetic (or ferric) oxide. Further, it would appear that since, in modern puddling, the greater part of the oxidation which takes place is due to the action of the cinder, this question of the amount of the dissolved oxide is of the highest economic importance. The ferrous silicate melts easily, and can be used in a form which costs next to nothing, and obviously it must be economical to have the highest proportion of this material present which is consistent with good working.* On the other hand, ferric oxide (which is an essential constituent, and often the source of magnetic oxide) is necessary, but dear. Too large a proportion of magnetic oxide, therefore, means preventible loss of fettling, while too small a proportion will involve the use of more time, a larger total weight of cinder, and consequent waste of fuel.

For these reasons I contend that a knowledge of the weight and composition of the cinder produced in puddling is of the highest practical value in enabling us to judge of the success of the process. It will, of course, be understood that in these and the subsequent remarks, I am merely endeavouring to elucidate the main principles which underlie the puddling process, and not to dogmatise or to lay down any hard and fast lines of procedure which it is obviously impossible to do in a case like the present, where the operation is conducted on small quantities at a time,

* Though ferrous silicate itself has comparatively little oxidising power in the puddling furnace, it doubtless acts as a carrier of atmospheric oxygen from the furnace gases, and thus contributes to the oxidation of the impurities present.

on nearly all varieties of pig iron, and with many kinds of fettling, and when success or failure is so often dependent upon the skill and attention of the workman.

In the ordinary process of puddling there are two distinct varieties of cinder produced, and the difference between the two is generally overlooked, though I think this difference is of great importance. The first variety of cinder is usually known as "boilings," from the fact that it boils over the foreplate during the heat, and is collected in the tapping-waggon. The second kind is known as "tappings" and is tapped out at the end of the process. The "boilings" are usually more or less honeycombed in structure, and are more easily fractured than the tappings, which are, on the other hand, more compact and dense. The tappings are free from metallic iron, while the boilings always contain some shots or globules of metal, which are carried over by the turbulence of the boil, and in some specimens recently examined I found as much as 16 per cent. of metal in the form of small globules, which were separated by a moderately powerful magnet from the crushed cinder. These globules of iron still retain carbon, and, being in contact with an oxidising slag, they produce carbonic oxide, which burns in jets at the surface of the molten cinder. The tappings, on the contrary, usually evolve little or no combustible gas. I think it may be considered, as a general rule, if the tappings are very lively in the waggon while hot, and very honeycombed and brittle when cold, that the process is not so satisfactory as when the boilings are more quiet and compact. Now it is somewhat remarkable to find how differently experienced men work these two varieties of cinder. Thus, while Mr. Harrison, a manager of many years' experience in South Staffordshire, advocates the production of practically no boilings, but retaining the whole of the cinder in the furnace till the end of the process, the figures given by Mr. Barrows earlier in this paper show that at one of the best works in the district they produce about an equal weight of tappings and of boilings. And yet another manager, who would prefer to have his name unmentioned, but to whose experience and practical knowledge I attach the very highest importance, recommends that so far as possible all the cinder should be boiled out, and only so much allowed to remain as can be carried to the hammer with the balls. But all will, I think, agree that the balls should, when taken to the hammer, retain a considerable quantity of tolerably thick cinder, which should so adhere to the iron as not to leave a trail behind on the way to be shingled, and yet which, when under the hammer, should cover and almost bathe the metal in slag.

For the purpose of my experiments, by the kindness of gentlemen who are or have been students in the Metallurgical Laboratory at Mason College, I obtained three sets of samples from different works—namely, samples of three heats from Mr. T. Ashton, of Netherton, one heat from Mr. Tolley, of Darlaston, and three heats from Mr. Barrows, of Bloomfield. The samples, therefore, represented seven heats worked under ordinary conditions, and in each of which satisfactory iron was produced; they were collected from different works using various kinds of iron and varieties of fettling. In this way it was hoped to obtain a mean result, which would as fairly represent the general practice as is possible under the circumstances. The samples were first crushed and treated with a magnet to extract any metallic iron that was present. In each case the boilings contained shots of iron, while the tappings were free from such metal. The mean composition, as deduced from the seven heats, was as follows:—

	Boilings.		Tappings.
Ferric oxide (Fe_2O_3)	6·94	...	12·90
Ferrous oxide (FeO)	62·61	...	64·62
Silica (SiO_2).....	19·45	...	15·47
Phosphoric anhydride (P_2O_5) ...	6·82	...	3·91
Not estimated (MnO, S, CaO, &c.)	4·68	...	3·10
	100·00		100·00
Total iron	53·55	...	59·29

I have not ventured to calculate how much of the ferrous oxide was combined with silica and phosphoric anhydride and how much oxide of iron was free, on account of the uncertainty as to the exact composition of the silicates and phosphates of iron that occur in tap cinder. The above figures, however, show a marked difference in the composition of the two kinds of cinder, the boilings being richer in silica and phosphoric anhydride, while the tappings contain more ferrous and ferric oxide, and consequently more iron. I know that blast furnace managers who use puddling cinder have a decided preference for tappings, and this is only what would be expected from the above analysis. This difference in composition is connected with the fact previously noticed, that the greater part of the silicon and phosphorus are oxidised during the earlier part of the process. Now, it is obviously necessary that these impurities should be oxidised and pass into the slag if a good product is to be obtained; but experience also shows that in order to produce a good iron it is necessary to have a fairly pure tapping cinder, as otherwise the impurities are either not wholly removed, or, if removed, they may actually pass back into the metal again. But if we wish to have economical working, the consumption of fettling must be reduced as much as possible; while, if we desire a pure product, the cinder must be rich and pure. How, then, are these two apparently opposite conditions to be obtained?

The purification of iron by oxide has been referred to as a "washing" process, and in an earlier part of this paper I have compared it to a "pickling" process. Certainly the final separation of slag from the granules of iron is not unlike the washing of a precipitate in the laboratory. If, for the sake of illustration, we consider the case of a quantity of oxide of iron contaminated with a soluble salt, and assume that the material will in the moist state retain one volume of the washing water. If then the oxide of iron be agitated with 100 volumes of water and filtered, the amount of remaining impurity will be only $\frac{1}{100}$ of the original quantity. But if the oxide were agitated with 10 volumes of water, and filtered, the impurity would be reduced to $\frac{1}{10}$; and if it were again treated in the same manner with 10 volumes of

Digitized by Google

water, the impurity would now amount to only $\frac{1}{100}$ of that originally present. Thus, by twice washing with 10 volumes of water, we obtain the same result as by the use of 100 volumes with a single washing. Now it seems to me that this principle is applicable to puddling cinder, especially when very impure pigs are to be used. Enough fusible cinder should be used to produce a bath sufficient to cover the metal as it melts, and this cinder need not be of an expensive character, since hammer-slag and similar materials are cheap. The character and proportion of ferric oxide in this cinder must, of course, be varied according to the pig to be treated, the object in each case being to remove the greatest possible amount of silicon and phosphorus at the beginning of the process. Having thus transferred the impurities from the pig iron to the cinder, and as far as possible *saturated the cinder with impurities* (which is, I believe, the key to economy at this stage), this cinder should be removed from the furnace, and this is most easily done, not by tapping at this stage, as was formerly the custom at some places, but by regulating the damper so as to produce a good boil, and thus boiling out the impure cinder into the tapping-waggon. Care must, however, be taken to avoid undue loss of metal in the form of globules at this stage, and the boiling cinder should be tested occasionally by crushing in a mortar, sieving, and treating with a moderately powerful magnet.

It must also be borne in mind that it is easy to spoil the iron by having either too little cinder or a too fluid cinder during balling, as this leaves the finely divided metal exposed to oxidising gases at a critical stage of the process. In puddling unusually pure iron, or metal that is more apt to produce a deficiency than an excess of cinder, obviously the foregoing reasoning with regard to the boilings does not apply, and it may in such a case be best to produce little or no boiling cinder. The general practice of the present day is to use much more impure pig iron than was the case forty years ago, and hence the importance of a correct knowledge of the composition of cinder at different stages of the process becomes more necessary. It is perfectly certain that it is possible, by the use of a sufficiency of cinder, by thoroughly boiling the iron, and by boiling out a good deal of the first cinder, to produce a splendid bar iron from very impure materials, and the quality of the finished iron often depends more upon the details of manipulation than upon the chemical composition of the original pig iron.

The average composition of the three samples of tappings and boilings previously mentioned is given in the following table, from which it will be seen that the amount of ferric oxide in the boilings is fairly uniform, and does not vary over a wide range in the tappings, while the other constituents show considerable differences, though in each case the same fact is noticed—namely

	Boilings.			Tappings.		
	1. Three Heats.	2. One Heat.	3. Three Heats.	1. Three Heats.	2. One Heat.	3. Three Heats.
Ferric oxide (Fe_2O_3)	6·28	7·53	7·40	13·24	11·61	14·00
Ferrous oxide (FeO)	59·91	63·96	64·86	59·83	67·46	68·46
Silica (SiO_4)	19·31	17·12	20·38	18·12	11·02	14·29
Phosphoric anhydride (P_2O_5)	7·68	7·62	4·52	4·90	5·06	2·53
Not estimated.....	6·82	3·77	2·84	4·91	4·83	0·72
	100·00	100·00	100·00	100·00	100·00	100·00
Total iron.....	51·00	54·91	55·63	55·10	60·60	63·05

that the boilings contain more phosphorus and silicon, and less oxides of iron, than the tappings. But when it is found that, in slags from different works conducting the same process, variations exist which amount to more than 50 per cent. of the silica present (viz., 11·02 and 18·12 per cent.), and to just over 100 per cent. in the amount of phosphorus (2·53 and 5·08 per cent. respectively), the question naturally arises whether these slags are equally economical, and whether it is possible in any simple manner to determine the relative economy of various samples of puddling cinder.

To do this it is necessary to have some standard of comparison, and to obtain a satisfactory standard is not easy, while it would probably be impossible to get any one standard which would be of general application. Thus I can only hope to suggest an approximation to the truth. But it is fully settled, I think, that a puddling cinder may be an efficient purifier and yet contain as much as 20 per cent. of silica and 8 per cent. of phosphoric anhydride. Possibly even more impurities than this might be permitted, and with a reduction of silica more phosphorus could be allowed, and *vice versâ*. Still experience shows that such a cinder is efficient, and we may, for purposes of comparison, regard this as a saturated boiling cinder. But the above table shows that we have usually about 5 per cent. of other constituents which were not separately estimated, while the ferric oxide is very fairly constant at about 7 per cent. Hence, as the composition of a boiling cinder for comparison, we may take—

Ferric oxide (Fe_2O_3)	7
Ferrous oxide (FeO)	60
Silica (SiO_2)	20
Phosphoric anhydride (P_2O_5)	8
Other constituents.....	5
	100

Such a slag as that above given contains scarcely any FeO in addition to that necessary to neutralise the SiO_2 and P_2O_5 on the assumption that the compounds $2FeO,SiO_2$, and $3FeO,P_2O_5$ are formed. On examining the table of analysis, it will be found that sample No. 1 agrees almost exactly with the suggested composition, while sample No. 2 is lower in silica, and No. 3 considerably lower in phosphoric anhydride than the standard. These are, therefore, unsaturated cinders, and are, for that reason, less economical, since either rather less fettling, or a cheaper kind of fettling, or a more impure iron, could have been used without interfering with the purification so far as the boiling stage is concerned.

If it is difficult to suggest a standard of comparison for boiling cinder, it is more difficult still to lay down any definite rule in the case of tapping cinder, on account of the variety in the quality of the iron to be produced, the weight of the tappings, and other causes. The following would, however, be tolerably economical and sufficiently pure for most purposes:—

Ferric oxide (Fe_2O_3)	12
Ferrous oxide (FeO).....	60
Silica (SiO_2)	18
Phosphoric anhydride (P_2O_5)	5
Other constituents.....	5
	100

On comparing the table of analysis, it will be noticed that sample No. 1 is again very nearly of the character suggested, while No. 2 is low in silica, and No. 3 rather lower in silica, and considerably lower in phosphorus. It must of course be remembered that this sample is from very best iron, and the apparent extravagance may be to some extent necessary.

To appreciate the importance of this question, it is only necessary to calculate the effect of such difference of composition as is here noticed on the annual cost at a large works. Thus, No. 3 sample of tappings contained 10·45 per cent. of Fe_2O_3 and FeO together in excess of what is necessary, if it is possible to work with the composition I have given. The oxide so calculated is pure, and equal to best tap at 17s. 6d. per ton. The tappings are, in round figures, 1 cwt. per heat, or 6 cwt. per turn, or about 50 cwt. per week per furnace; 10 per cent. of this gives 2½ tons, which, at 17s. 6d. per ton, would cost £2 3s. 9d. per furnace per week, which, in an ironworks of the largest size, with, say, fifty puddling furnaces, would mean £5,000 per annum.

Before closing this paper, I should like to say a few words as to the probable nature of the changes which take place during the oxidation of the impurities of the pig iron during the puddling process. I have previously referred to the fact that a number of actions are possible, some of which involve the use of much more fettling than others, some of which yield much iron, and others none. Now, any explanation which may be suggested must be in harmony with the observed facts, such as:—That oxidation is carried on by oxide of iron, which is partly produced from the pig iron itself, but chiefly supplied in the form of fettling. Ferric oxide alone is too infusible to play an important part in the process, but acts when dissolved in cinder. Puddling cinder consists largely of ferrous silicate, which is readily fusible, but not easily reducible, and which amounts to two-thirds of the whole slag in the early part of the process. Puddling cinder contains magnetic oxide of iron, which is present in greatest proportion in the tappings. The amount of ferric oxide present is usually pretty constant at the same stage of the process in different heats, and increases as the purification of the metal progresses. Impure pig irons do not necessarily give the smallest yield of puddled bar per unit weight of pig iron used, the contrary being particularly noticed with very common irons. The weight of puddled bar obtained may exceed the weight of pig iron used, especially if plenty of suitable fettling has been used, and the metal well boiled, so as to give a pure product.

Now, so far as I can at present see, these conditions involve the reduction of both ferric and ferrous oxides together according to an equation of the following type:—

$$xFe_2O_3 + yFeO - zO = 2XFeO + yFe,$$

in which, starting with ferric and ferrous oxides, by the removal of oxygen, ferrous oxide and iron are obtained. If we consider ordinary magnetic oxide (Fe_3O_4), this equation would become

$$FeO,Fe_2O_3 - O_2 = Fe + 2FeO,$$

and such an equation probably represents a close approximation to what actually takes place in many cases, since we know that both FeO and metallic iron are produced. The relative amount of each will doubtless depend upon the conditions which exist in any case under consideration, and more particularly upon the proportion which exists between the oxidising power of the slag, and the kind and amount of impurities which have to be removed.

A consideration of the thermal aspects of this question supports the view that ferrous oxide or ferrous silicate take but little part in the oxidation under ordinary conditions. The heat developed by the combination of 1 gramme of iron with oxygen in different proportions is approximately as follows:—

1 gramme of iron oxidised to		Fe_2O_3	yields	1,725	calories.
1	,,	,,	Fe_3O_4	,, 1,600	,,
1	,,	,,	FeO	,, 1,350	,,

By calculating from these numbers the amount of heat required to liberate the same quantity of oxygen for each of the three oxides, we obtain the following values:—

To liberate a unit weight of oxygen and produce metallic iron from	FeO	absorbs	1,350	calories.
,, ,, ,, ,,	Fe_3O_4	,,	1,200	,,
,, ,, ,, ,,	Fe_2O_3	,,	1,150	,,

Now, since more heat is required to obtain an equal weight of oxygen from FeO than from either Fe_3O_4 or from Fe_2O_3, obviously but little FeO will be reduced so long as higher oxides are present; but in tap cinder much, at least, of the FeO is already combined with either SiO_2 or P_2O_5, and this would render the reduction of the iron still more difficult. Of the remaining two oxides, Fe_2O_3 is somewhat more readily reduced than Fe_3O_4, but much more infusible, and, as we have seen, oxidation is carried on in the puddling furnace chiefly by the fluid cinder which contains magnetic oxide. Hence it is not unreasonable to suppose that the infusibility of ferric oxide would counteract the slight advantage it possesses in reducibility, and that the main reaction is of the type above given.

Further support of this view is afforded by the results of some of my own experiments performed six years ago (*Jour. Chem. Soc.*, 1885, p. 474), in which it was observed that, on fusing silicon pig in a crucible with ferrous silicate, the proportion of silicon and manganese was but very slightly reduced, while these elements were rapidly oxidised by slags containing ferric oxide, or by the action of atmospheric air. I then concluded that ferrous silicate, apart from atmospheric oxidation, has very little influence on silicon or manganese in pig iron, and stated that:—"From the fact that manganese is more readily oxidisable than iron, it might have appeared that ferrous silicate would itself probably act as an oxidising agent in removing manganese from pig iron. But these experiments appear to show that the real action of ferrous silicate is rather that of a carrier of oxygen than of a true oxidising agent. Ferric oxide is first formed, and this is reduced by the bath of metal present."

On the other hand, an experiment performed by Mr. Stead (*Cleveland Engineers*, 1877, p. 153), in which a small quantity of pig iron was fused with an excess of oxide of iron, chiefly in the form of ferrous oxide, appears to prove that phosphorus is oxidised by ferrous oxide, and that, at the same time, it reduces an equivalent amount of iron from the slag. This experiment is scarcely conclusive, as no account was taken of other elements present in the pig; but if ferrous oxide removes phosphorus and reduces an equivalent amount of iron, while silicon and manganese are oxidised by ferric oxide and reduce no iron from the slag, this would explain some of the apparently anomalous yields obtained with certain common irons, to which I have before referred. Too much importance must not be attached to crucible experiments, however, as the conditions are not the same as those which obtain in the puddling furnace, and additional experimental evidence is required in order to further elucidate some of these points.

It may, in conclusion, be necessary for me to again remind you that my paper is intended to partake more of the character of a contribution to the discussion of a subject which is of interest to many members of this Institute than as a dogmatic assertion of fixed and unalterable views; and if what I have said should be of use in assisting to clear up some points which are obscure, and in causing others with wider opportunities for practical observation to investigate the matter more fully, I shall feel that the object I had in view when this paper was commenced has been fully realised.

THE ROYAL NAVAL EXHIBITION.

ELECTRIC LIGHTING PLANT.

The necessary arrangements for the electric lighting of this Exhibition having been entrusted by the executive to Messrs. Siemens Brothers & Co., it was decided by this firm to carry out the same on the lines of a small central station, and for this purpose an engine and dynamo room 68ft. long and 29ft. wide was provided, but, after deducting from these dimensions the space apportioned to visitors, there remained a floor area of only 48ft. by 21ft. whereon to erect six sets of engines and dynamos, aggregating collectively over 1,100 h.p. In addition to this building, a boiler-house measuring 60ft. by 29ft., and containing seven steel boilers constructed by Messrs. Davey, Paxman, & Co., was also provided.

Briefly, the general lighting may be said to be effected by some 200 1,000 (approximate) c.p. arc lamps and upwards of 2,000 Edison-Swan 16 c.p. incandescent lamps, suitably dispersed about the various galleries, grounds, kiosks, &c. The arc lamps, of Siemens' new pattern—similar to those in use at the British Museum—are run two in series, and work with a current of 9 amperes each, those employed for illuminating the galleries being suspended from the ribs of the roofs, while those used in the grounds are hung in groups of six, on 40ft. lattice iron masts. To supply the current required for these 2,200 arc and incandescent lamps, also numerous motors (used for working models in various parts of the buildings), and the lighthouse lamps, Messrs. Siemens Brothers have installed five of their continuous current dynamos and one separately excited alternator, the leads from all of which are taken to a switch-board (of the firm's central station engine-room type), provided with all necessary controlling, regulating, and measuring instruments, magnetic, and other cut-outs. From the switch-board the current is led by means of Siemens' lead-cased and iron-sheathed underground feeding mains to the network of distributing conductors placed throughout the buildings and grounds.

As the continuous current dynamos used are substantially the same as the makers' latest type, recently described by us (see *Industries*, Vol. X., page 401), we need not again refer to details of construction, nor does the alternator, being of the well-known type, need description here. It will therefore suffice for descriptive purposes to consider the plant as divided into two groups, the first consisting of three of the makers' shunt-wound dynamos (type H.B. 24/36), each capable of giving an output of 1,500 amperes at a pressure of 120 volts whilst absorbing 260 h.p. Driving power is supplied by three of Willans' central-valve engines, each indicating about 300 h.p., with steam at 120lb. boiler pressure, and when running at the required speed of 350 revolutions per minute. Each of these units occupies a base area of 108·5 square feet (*i.e.*, 15ft. 6in. long by 7ft. wide), and stands 9ft. high, the combined efficiency of engine and dynamo at full load being given as about 86 per cent. It is claimed that, with one exception, these are the largest direct-coupled high-speed engines and dynamos in existence, and that they, in themselves, are a sufficient generating plant for a fair-sized lighting station, as they are capable, if worked together, of supplying current for upwards of 8,000 16 c.p. lamps.

The second group is made up of three units, the first consisting of one H.B. 15/19 dynamo coupled direct to a Willans vertical open type engine. The bed-plate on which these are mounted is 8ft. 6in. by 3ft. 3in., and the whole would stand with a headroom of 5ft. 3in. This dynamo, when running at 320 revolutions per minute, is equal to an output of 200 amperes at a pressure of 120

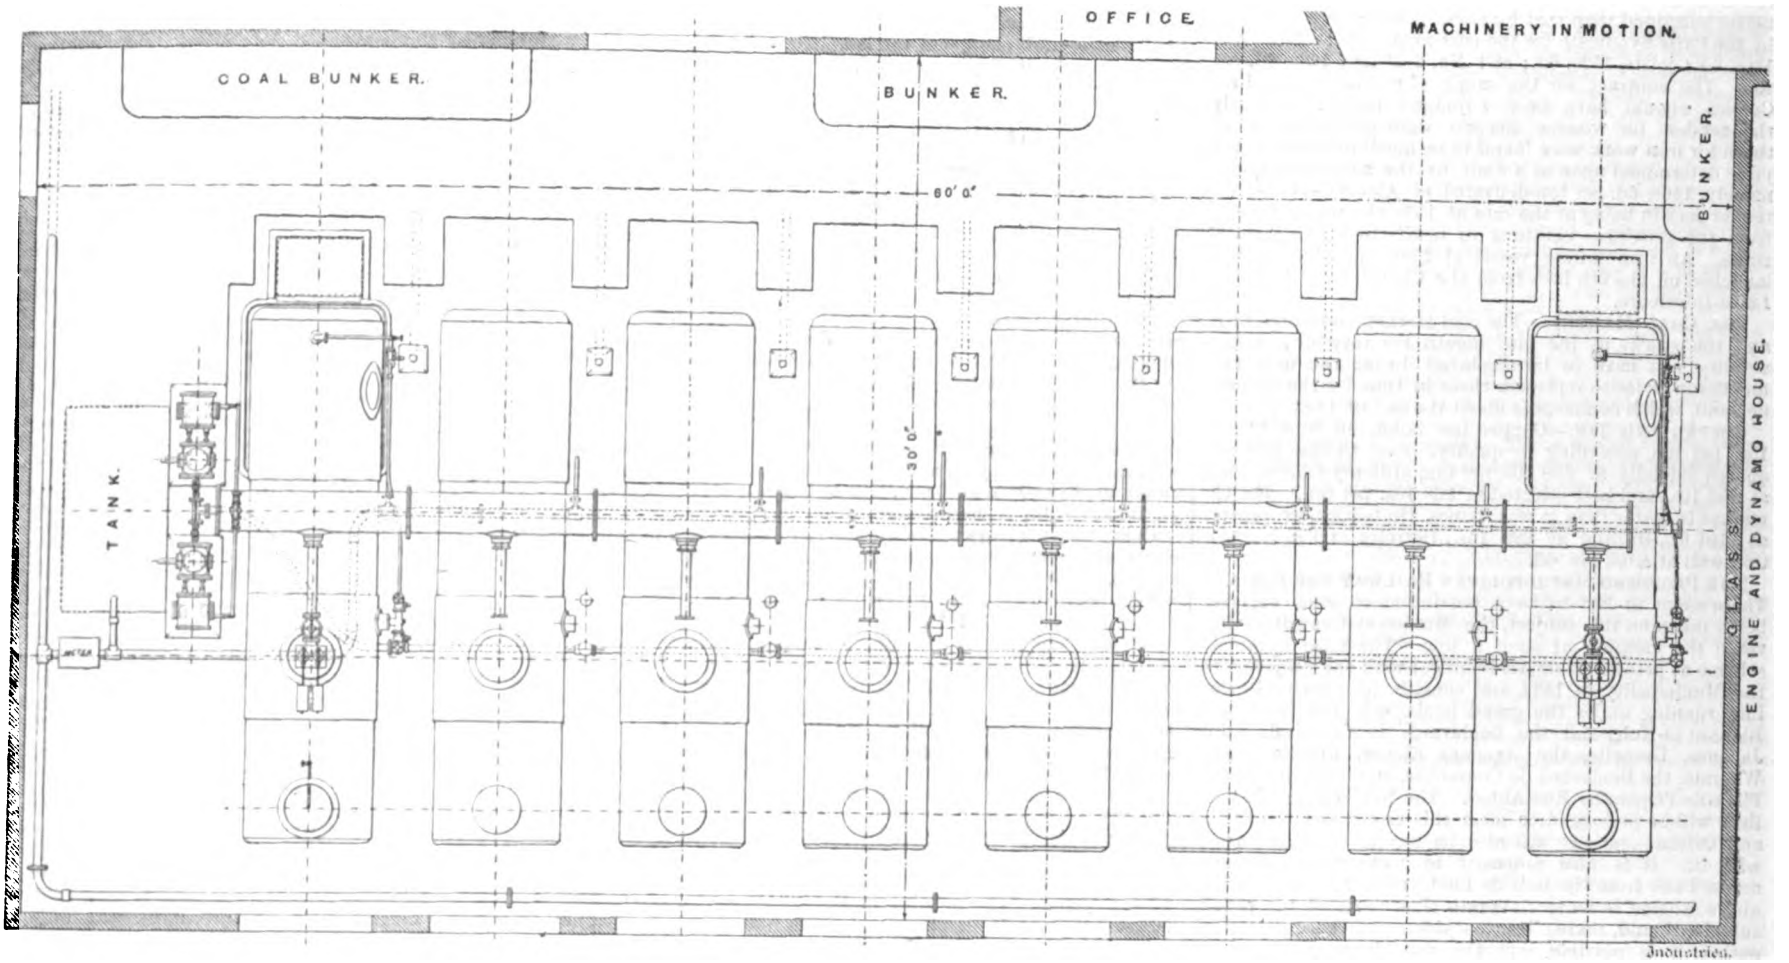

Fig. 1.—Plan of Boiler House.

volts. The second unit of this group, occupying a space of 8ft. 6in. by 4ft. and standing 6ft. high, is made up of one H.B. 16/19 dynamo coupled direct to a Willans engine, and gives an output of 400 amperes, under 120 volts pressure, when running at 475 revolutions per minute; while the remaining unit, devoted to maintaining the arc lamp of the lighthouse, yields, by means of a Siemens W_{20} separately excited alternator, running at 420 revolutions per minute, an output of 40 kilowatts (*i.e.*, 500 amperes 80 volts). This is also driven by a Willans engine, the over-all dimensions being 5ft. 3in. by 9ft. 6in. by 6ft. 9in. The following are brief particulars of the engines above mentioned:—

The large engines are of the double-expansion compound non-condensing type, having three pairs of tandem cylinders, mounted, high-pressure uppermost, over a three-throw crank shaft (120 degrees between each throw), the high and low pressure pistons being 14in. and 20in. in diameter respectively, and 9in. stroke. These engines, standing on a base 7ft. 8in. by 3ft., indicate, as before stated, 300 h.p., and when doing so consume about 20lb. of steam at 120lb. pressure per indicated horse-power per hour, but similar engines fitted for condensing and working with steam of 160lb. pressure have been proved to require only 14lb. of steam per indicated horse-power per hour. We purpose illustrating and describing this engine in an early issue.

The G.G. type engines are compound non-condensing four-cylinder engines, having 8in. high-pressure and 14in. low-pressure pistons and 6in. stroke. These engines, numbers of which have been supplied to the Navy, stand on a base of 3ft. 8in. by 2ft. 4in., and are 5ft. high. With steam of 120lb. pressure they indicate 80 h.p. when running at 475 revolutions per minute. The open-type engine differs from those above described in that it has steam-jacketed low-pressure cylinders, and, as its name implies, all below these, such as piston and connecting rods, guides, cranks, &c., are open, as in the ordinary type of inverted cylinder engine. The steam to the high and low pressure cylinders is controlled by piston valves placed outside these cylinders and driven by eccentrics in the ordinary way. This engine, when running at 350 revolutions per minute, indicates 60 h.p.

Steam is supplied to the several engines mentioned by a battery of seven steel locomotive-type boilers constructed by Messrs Davey, Paxman, & Co., of Colchester,

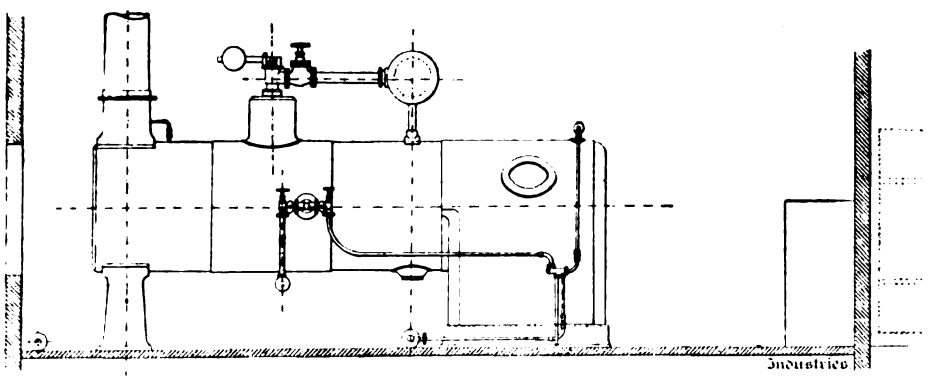

Fig. 2.—Part Sectional Elevation

and shown in plan and elevation in Figs. 1 and 2, the boiler-house in which they are placed measuring 60ft. by 29ft. In addition to these the same makers have supplied two other boilers, or nine in all, of exactly the same construction, and which latter are placed contiguous to the Camperdown Gallery for driving the various machinery therein. Each of the boilers has a grate area of 16½ square feet and 710 square feet of heating surface. They were constructed for a working pressure of 140lb., and each has been carefully tested, hydraulically, to 250lb. per square inch. The inside fire-boxes were made from Messrs. Davey, Paxman, & Co.'s special mild steel, all flanging being done by special hydraulic machinery, and, as an additional precaution, every plate was most carefully annealed after passing through the various machines. All the plates, planed or turned on their edges, had the rivet holes drilled in position, and closed by special quality steel rivets. A steel receiver, made up of 6ft. 6in. lengths, the flanges whereof are welded on, runs across the entire battery, and into this each boiler discharges its steam, provision being made, by means of suitable stop valves, to allow of the opening or shutting off of any of the boilers. The feed-water for the electric light boilers, each of which evaporates over 3,000lb. of water per hour, is supplied by two of Mumford & Anthony's "Duplex" steam pumps, and, in addition, each is fitted with a Gresham & Craven injector.

In closing this necessarily cursory description of the electric lighting plant at the Exhibition, we may congratulate the executive upon the successful termination of the excellent and efficient arrangements made by each of the firms interested, and upon the satisfactory working of the whole installation.

RAILWAYS IN ILLINOIS, U.S.A.

Illinois has the greatest railway mileage of any State in the Union, having 10,163 miles of main line, 926 of second, third, and fourth tracks, and 2,928 miles of sidings. The total capital stock, funded debts, and current liabilities of the railway companies in Illinois for all mileage operated in 1890 amounted to £403,236,785, or £10,833 per mile, and the net income on 41 railways was £6,591,582, while 21 railways showed a net deficit of £285,391. The total earnings from operation in Illinois in 1890 amounted in the passenger department to £3,600,805, in the freight department to £9,924,453, and from miscellaneous sources to £390,266, making the total earnings £13,915,524, and showing a slight increase in the passenger traffic and about 10 per cent. increase in freight returns over the preceding year. The operating expenses in 1890 were £2,646,438 chargeable to passenger traffic, and £5,612,917 to the freight department, total £8,259,355, an increase of under 2 per cent. on the year 1889.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 16th June, 1891.

The Iron Market.—There is no change in the state of the iron market. The demand for joists continues to be better sustained than that for bars. The prices established by the Paris Syndicate for the past week were:—Best bars, 140s. 6d.; joists, 152s. 6d.; and No. 2 sheets, 168s. 8d. per ton. The contract for the supply of railway material for Corsica should have been adjudged to-day, but only the tenders for wooden sleepers were accepted, as all those for iron work were found to be much in excess of the price determined upon as a limit by the administration—namely, 146s. 6d. per ton delivered at Ajaccio—the lowest tender sent in being at the rate of 153s. the ton. Reports from the provinces continue to testify to a fair state of trade. An iron sailing vessel of 2,000 tons burden was launched on the 6th inst. from the Chantiers de la Loire, Loire-Inférieure.

The Coal Market.—The coal market continues firm, and the stocks at the pits' mouth are very low. Great activity will have to be displayed during the next two months in order to replenish these in time for the autumn demand, which commences about the end of August.

Copper and Tin.—Copper has fallen off from 12s. to 15s. per ton, according to quality. Best Chilian bars are quoted officially at £58 10s. per ton, ordinary Chilian bars at £56 10s., and best selected at £60 10s. per ton. The tin market is better than it was, Banca tin being now quoted at £101 9s., Billiton at £99 16s., Detroits at £98 9s., and Cornwall at £103 17s. 6d.

The Proposed Metropolitan Railway for Paris.—There seems at last to be a possibility of some decision being taken on this subject, the Municipal Council having voted the creation of such a line. The most approved scheme at present is almost identical with one proposed to the Municipality in 1883, and consists in a main circular line running under the grand boulevards, the Boulevard Richard-le-Noir, and the Boulevards de l'Hôpital, Saint Jacques, Grenelle, the Avenues Kléber, Friedland and Wagram, the Boulevard de Courcelles, and returning to the Place de l'Opéra by Rue Auber. The Northern and Sceaux lines will be prolonged to meet this circle, and the Lyons and Orleans stations will also be put in communication with it. It is also proposed to make a line running across Paris from the Bois de Boulogne to Vincennes. The above scheme is more elaborate than most of the others submitted, and, taking into consideration the question of outlay, it is possible that the committee appointed to examine into the question may reject it.

The Panama Canal.—M. Charles de Lesseps has published a letter in the Parisian journal, *Le Jour*, which says that his father and himself will shortly be able to make a statement with reference to their administration of the affairs of the Panama Canal Company, and to explain the motives of their past action.

BERLIN, 15th June, 1891.

The Iron Market.—The demand for rails on the part of the Breslau State Railway management has generally amounted during the first half of each year to 4,000 tons, but this year the demand is considerably greater. An order for 15,330 tons of steel rails has already been placed with the Royal Laura Works and the Upper Silesian Supply Company. The rolling mills will, therefore, be well supplied with work for some time. The price offered by both works for steel rails was £6 4s. 4d. per ton.

The Coal Market.—Tenders for patent fuel, nut coals, furnace, and foundry coal were recently invited by the management of the Right Bank Rhenish Railway. No offer was made for 20,000 tons of patent fuel; the lowest offer for 4,500 tons of foundry coal was made by the Gelsenkirchen Mines, which offered coal at 10s. 2d. per ton, delivered at the Germania Pit.—A seam of coal has been bored into at Welsberg, near Schattenstein, in Oberfranken, and a company is being formed for the purpose of working it.

Woollen and Cloth Trades.—The condition of the cloth market has been unfavourable in some important respects. Notwithstanding the severity of last winter, business in the poorer and moderate sorts of wool was confined within narrow limits, and was less than that of previous years. For better and superfine sorts the market was satisfactory. The lessened sale of the poorer wools is shown by the diminished earnings caused by the strikes. Wool merchants are despondent about forward orders for next winter, especially since the spring business did not develop in consequence of the continuance of severe weather. Business in light woollens did not become active till the beginning of May. The regular demand for raw material has decreased very little, and prices have been well maintained, so that manufacturers frequently find business unremunerative.

Regenerative Petroleum Lamp.—Mr. Julius Schnelke, of Berlin, has recently constructed a petroleum lamp which is similar in working to the Wenham and Clarke gas lamps. The petroleum is evaporated in a chamber, and after having passed through a ring of small tubes is burnt as a gas without a wick, and produces an inverted flame. The products of combustion serve for the heating of a system of baffle plates, by means of which the air necessary for combustion is well heated before reaching the burner. The flame is perfectly white, and the regulation of the oil, which flows from a reservoir above, is easily effected by a needle valve, which at the same time secures the entrance of a clean oil into the lamp. The heating of the evaporating chamber is effected by a small flame, which is fed either by petroleum or by spirit, and which is automatically extinguished as soon as the evaporation of the oil has commenced, and the lamp is in working order. Photometric trials show that the lamp has a high illuminating value per unit of oil consumed.

VIENNA, 15th June, 1891.

The Iron Market.—The general condition of the iron market has not changed during the past week, and prices remain stationary. Notwithstanding the brisk demand for all sorts of iron, it is impossible for manufacturers to raise the prices, as foreign markets would then be able to compete successfully with our own market. The price of pig iron only has increased, and shows a firm tendency, whilst a good business is being done in rolled iron. Bohemian firms are very well represented in the Jubilee Exhibition at Prague, and it is evident that the Bohemian machine works are the most important works in Austria. The total value of the engines which are constructed in Bohemia annually amounts from £1,350,000 to £1,950,000. The capital invested in these works is nearly £2,000,000. From 7,000 to 10,000 workmen are employed, and the wages paid amount annually to £480,000 to £500,000. The production of Bohemian pig iron amounts to 200,000 tons.

Electrical Engineering.—On the 11th inst. a large electrical central station at Carlsbad, in Bohemia, was started. The installation consists of five Babcock-Willcox boilers, each with 1,310 square feet of heating surface. Four steam engines of 125 h.p. each and 360 revolutions have been supplied by the Brunn Machine Works. The engines are directly coupled with the alternating current dynamos, and also drive the exciters. The dynamos are of the A. 6 type, constructed by Messrs. Ganz & Co. in Budapest, and have an output of 80,000 watts at a pressure of 2,000 volts. The central station is situated at a distance of about 1¼ miles from the town, to which the current is carried by a conductor above ground of 8mm. diameter. The current is distributed through the town by an underground cable, of which about 12½ miles have been laid, and the secondary conductors also are carried underground. The public transformers are on the Zipernowsky-Déri-Blathy system. The lighting of the streets is effected by 90 arc lamps at 12 amperes and about 180 incandescent lamps of 16 c.p., which, however, do not work simultaneously. Private establishments in the town have been anxious to adopt electric lighting, and nearly the whole of the output of the present installation has been applied for. At Prague an electrical railway has nearly been completed. A mountain railway is being constructed by Herr Krizik to the Belvedere, and thence an electric railway of about 2½ miles is being made to the Exhibition ground in the Baumgarten. Austrian firms continue to take a prominent part in the Frankfort Electrical Exhibition. Professor A. von Waltenhofen, director of the Electrical Institute in Vienna, has been elected a member of the committee of awards.

BRUSSELS, 16th June, 1891.

The Iron Market.—The market has again become slack owing to the lowering of the price of pig iron in England. There is, however, some hope of a rise in consequence of the favourable state of the French market. Constructive works are well supplied with orders. Some large contracts for fish plates have just been awarded, as well as for a supply of metal frames and supports for the repair of works at Maestricht. The Liége works are constructing some mechanical separators for the coal mines at Werister.—On comparing the exports of the first four months of this year with those of the corresponding period of last year, it is found that the exports of steel have considerably decreased. Steel rails show a decrease of 11,000 tons; miscellaneous steel work, 10,000 tons; manufactured steel, 1,000 tons; miscellaneous rolled iron, 4,500 tons; manufactured iron, 2,000 tons; cast iron, 7,000 tons; rolling stock, 5,000 tons; machines, 6,300 tons—making a total of 46,800 tons. The imports have been maintained, with the exception of rough cast iron, which has decreased from 87,000 tons in 1890 to 30,000 tons in 1891.

The Coal Market.—The award of contracts, which is fixed to take place to-day, is awaited with some impatience. Supplies are decreasing in the Liége and Charleroi districts, and the price would possibly rise, if it were not for the import of French coal, which is of good quality. There is a large demand for coke, which is likely to rise in price again. Coke is now quoted at 14s. 10d.; screened coal, at 9s. 7d. to 10s. 5d.; lump coal, for furnaces, at 11s. 2d. to 12s.; household sorts, at 12s. 10d. to 16s. On the 17th inst. the Naval Department will award contracts for 12,000 tons of coal or patent fuel.

Electric Lighting.—The Julien Company has erected an installation of incandescent lamps of 20 c.p. in the large market of Ixelles, which are lighted by means of two batteries of Julien accumulators. Some installations have recently been carried out at Charleroi, in consequence of the success attending the central station erected by M. Dulait. At Antwerp the prospect of an arrangement with the gas company causes the former projects for the lighting of the town to be revived.

Linens and Textile Fabrics.—Linens and yarns imported from Russia have been offered at a low price, but little business has been done. For home made linens and yarns the market is very small. Linen threads show some activity, but manufacturers are well supplied with orders, and prices are very firm. Bruges has produced a larger supply of linen than usual, and there is a slight rise in price of the better qualities.

The Port of Brussels.—M. Van Mierlo, chief engineer of the public works in Brussels, M. de Paepe, chief engineer of the railway administration, M. Maillet, chief engineer of roads and bridges, and M. Dustin, have gone to Brême in order to visit the port, and will afterwards visit the port of Dunkirk.

DÜSSELDORF, 16th June, 1891.

The Iron and Steel Market.—The better tone which was recently apparent in this market has given way, and business in the pig iron market has again become inactive. For manufactured goods there is a good demand, and business shows a tendency to increase. The award of contracts for railway material continues, and on the 19th inst. a supply of 5,000 tons to 6,000 tons is to be placed by the Baden State Railways at Karlsruhe. The Dortmund Union has received from the State Railway management at Cologne an order for iron to be used in the construction of the railway station there at a cost of £78,300. The owners of the blast furnaces of the Rhenish-Westphalian Union, which produce Thomas iron, and the owners of the Luxembourg blast furnaces have arranged a common place of sale in Düsseldorf for phosphorised iron, which is used in the manufacture of steel and iron flux. The Bochum-Steuer trial has attracted much attention in industrial and other circles. Political relations in Bochum have been strained for some years past, and the Ultramontane, the Liberal, and Social Democratic parties have been bitterly opposed to one another. The leaders of the various parties have shown a bitter personal hatred. The journals which represent the Ultramontane party have published such insulting statements that the other party, with Mr. Baare, the general director of the Bochum Union, at their head, have felt compelled to institute an action for libel against the editor of an Ultramontane journal. The latter has replied by bringing an accusation against the Bochum Union before the Government authorities that false marks have been placed on the rails and axles for sale with the knowledge of Mr. Baare. The inquiry which has been instituted does not, so far, give much foundation for this accusation. It is unfortunate that accusations, which have been made against the Bochum Union without full proof, and probably from personal motives, should reflect on the iron industry throughout Germany.

The Coal Market.—The coal market remains firm, and prices are well maintained. In consequence of continued rain the Rhine has risen considerably, and shipments at Duisburg have in consequence been much decreased. The shipments, however, of Westphalian coal amounted to 110,000 tons.

Electric *versus* Gas Lighting.—A controversy is at present going on between Mr. Hegener, the former manager of the Cologne Gas and Water Works, and Mr. Riemer, an engineer of this town, as to whether the electrical central stations, which are now in course of construction in the larger number of the important towns of Germany, are likely to be profitable. Mr. Hegener is decidedly of opinion that they will not earn a profit, while Mr. Riemer, relying on the practical experience of Mr. Haniel and Mr. Lueg, regards the prospect of these installations as favourable.

AMSTERDAM, 15th June, 1891.

The Stearine Candle Factory at Gouda.—In 1883, when this company had been in existence for fifty years, a pension fund for the employés was started by the board of directors, who set aside £4,166 from the reserve fund for that purpose, and engaged themselves to pay into the pension fund an annual percentage of the profits for the benefit of the participating members. It appears from a recent report, that the pension fund has benefited to the extent of £16,312 from 1883 to 1890. Last year £1,660 was available for distribution, being equal to 21 per cent. of the total of the wages paid.

The Western Sugar Refining Company at Amsterdam.—In 1890 this undertaking made a clear profit of £36,976. After writing off £16,635, there remained a balance sufficient to pay a dividend of £9 3s. upon each share of £83. 43,500 tons of raw sugar were treated in 1890, against 32,500 tons in 1889.

Cinchona Culture in Java.—The official report of the Government cinchona plantation in Java states that the crop of 1890 amounts to 534,562lb., 142,396lb. being Cinchona succirubra, 6,447lb. Cinchona Josephiana, 342,271lb. Cinchona Ledgeriana, and 43,448lb. Cinchona officinalis. 100,000lb. of bark were collected in the first quarter of 1891. The bark sold at Amsterdam out of the crop of 1890 fetched 1½d. per unit for common kinds. The Cinchona Ledgeriana fetched good prices, and even better ones were realised by the bark of the Cinchona succirubra—viz., up to 2s. 4d. a pound. The "Melattie" Company's cinchona plantations in Java have done well in 1890, and the shareholders receive a dividend of 11 per cent., after placing £250 to reserve, and writing off £166.

Digitized by Google

DUTCH GUIANA.—At the opening of the States in Paramaribo, on the 12th ult., a report was read concerning the economical progress of the colony in 1890. It appears that Dutch Guiana produced last year 1,963 tons of Muscovados sugar, 6,149 tons of vacuum pan sugar, 1,168,962 litres of molasses, 532,239 litres of rum, 2,169 tons of cocoa, 572,113 bunches of bananas, 7 tons of coffee, 9 tons of rice, and 241 tons of corn. 1,380 immigrants arrived in the colony during 1890, among them the first Javanese labourers imported into the colony.

STOCKHOLM, 13TH JUNE, 1891.

THE GOTHENBURG EXHIBITION.—As the completion of the buildings in connection with this Exhibition advances, it becomes evident that it will be both extensive and interesting. The principal building is 336ft. long and 134ft. broad, but its accommodation is insufficient, and many auxiliary buildings have been erected in consequence. The exhibitors number about 1,000, and a great many of them intend to show machinery in motion driven by electricity. The whole of the buildings will be lighted by electricity.

DREDGERS.—The Munktell engineering firm has recently delivered several large dredgers. One has been supplied for Ystod, 85½ft. long and 22ft. broad, with a compound engine of 50 h.p., in addition to which there are two smaller engines of 5 h.p. each. The greatest dredging depth is 26ft., and capacity about 3,000 cubic feet per hour. A somewhat larger dredger has just been completed for Kalmar, but the largest will be the one just ordered for the town of Hango, in Finland.

NEW STEAMER.—The new steamer "Göteborg," built by the Bergsund Engineering Co., for the Bohnslön Steamer Co., had a satisfactory trial trip about a fortnight ago. The steamer is 160ft. long and 35½ft. broad, and is fitted with triple-expansion engines of 700 i.h.p.

CHRISTIANIA, 13TH JUNE, 1891.

THE NEW RAILWAYS.—The construction of the Nestun-Os Railway was commenced a few weeks ago. The period required for the completion of the lines, recently sanctioned by Parliament, will extend over six years. The annual grants were estimated to be about £166,000. The first lines to be completed will be the Kongsvinger-Flisen Railway, the Hamar-Lillehammer Railway, and the Lillehammer-Losna section of the Lillehammer-Sel line. The Söterdale Railway and the Losna-Sel section would be delayed until the second half of the term of six years. In accordance with this plan the Kongsvinger-Flisen line could probably be opened in the autumn of 1893, and the Hamar-Losna Railway a year later.

STATE GRANTS TO ENGINEERS.—The Norwegian Government having voted a sum to be distributed among engineers who do not hold State appointments, so as to enable them to complete their studies, this money has now been distributed. Among those who have obtained such assistance are men who are engaged in milling, telephony, the stone industry, and paper manufacture. The grants are for studies abroad, and the recipients have to send in to the authorities, within a year after their return, a full report of their work.

COPENHAGEN, 13TH JUNE, 1891.

THE RAILWAY WORKS AT SLAGELSE.—The large railway works at Slagelse, Sealand, are now rapidly progressing, the number of workmen having been recently increased. The digging machine, probably the first used in Denmark, has of late been worked both night and day. The larger bridges are well advanced, and some of the viaducts are already completed. The new railway station is also approaching completion.

LIFE SAVING APPLIANCES.—An exhibition of various life saving appliances took place at the new harbour, Copenhagen, on the 9th inst. A lifeboat of the most approved construction, capable of carrying thirty-five men, was first shown. Some instructive experiments with rocket firing were then made. Mr. O. Larsen, who has made a specialty of life saving appliances, had arranged an exhibition of his various manufactures, comprising patent oil distributors, life buoys, life saving garments and mattresses, and the Klickbüll life saving appliances. Messrs. Koefoed & Boge also showed their patent oil bag.

MEETING OF TELEPHONE DELEGATES.—A meeting of delegates and engineers from all the Jutland telephone companies is to be held at Aarhus to-morrow. In connection with this meeting several Danish and foreign firms have arranged an exhibition of telephonic appliances.

MADRID, 15TH JUNE, 1891.

HARVEST PROSPECTS.—It is feared that the barley and wheat crops will be much below the average of the past few years. Particular districts may, however, show some exception to this rule. Straw is likely to be even more scarce than grain. The profits of the Madrid tramway companies will be seriously diminished this year in consequence of the high price of barley. If a similar state of affairs were to continue for two years it is probable that the companies would substitute electrical for horse traction Up to the present time none of the four large companies has taken any steps to effect this improvement, although proposals are continually being made. One of the four companies is English, another Belgian, and the other two are Spanish. One of the Spanish companies, named "Estaciones y Mercados," seems rather disposed to adopt electrical traction.

IMPROVEMENTS AT BARCELONA.—On the 8th inst. tenders were to have been received for making the projected extensive improvements at Barcelona. No tender, however, was submitted, and the concession will be granted to the original applicant, Señor Baixeras. The project is likely to meet with much opposition from the shopkeepers whose houses are to be pulled down. According to the present law the contractor will be obliged to pay the estimated value of such buildings as are made use of for the proposed improvement, but compensation is to be made to traders for losses incurred through the removal of their business. It is, however, generally recognised that the present law is imperfect in this respect. It is rumoured that Señor Baixeras is supported by an English syndicate.

TELEPHONE SYSTEM IN VISCAY.—The provincial authorities of Viscay have decided to establish a complete system of telephones throughout the province, and to have a telephone station at each of the 122 municipalities which are situated in that energetic and prosperous district of the country.

PHOSPHATE MINES AT PEÑAFLOR.—A company has been formed in Belgium with a capital of £109,200 to work the phosphate mines of Peñaflor. No serious attempt has yet been made to work the mines, but a sanguine report has been accepted by the company, which states that there are 1,400,000 tons of phosphates in the mines. It is expected that 100,000 tons of phosphates will be obtained annually, out of which 26,400 tons will be of 75 per cent. quality. These mines are favourably situated for shipping purposes, as they are only 53 miles from Seville, and there is a railway through the whole distance with the exception of six miles.

ROME, 15TH JUNE, 1891.

ITALIAN LIGNITE.—Some experiments were recently made on the railroad from Rome to Frascati, in which lignite, distilled according to the process of Mr. Sapori, was used instead of coal. The experiments were made on a very heavy gradient, and only one engine was employed for the trip instead of two as usual, although there was a larger number of waggons and a considerable number of passengers. There was no unpleasant smell, and the consumption of lignite was less than coal, the boiler pressure being kept constantly at nine atmospheres. The trial has been considered very satisfactory, and it is hoped that the use of lignite instead of coal for the various industries will be advantageous from an economical as well as from a social point of view. The great importance attached to this subject by Italian manufacturers may be easily understood from the fact that Italy produces no coals, whilst it imports about 5,000,000 tons of coals per annum from abroad, of the value of over £5,000,000. After the experiments made in Germany many Italian engineers and manufacturers devoted their attention to lignite, and tried to find out the best method for adapting this fuel for industrial as well as for household purposes. Many works in Italy are now using lignite only, by means of the Siemens gas producers, among the most important being the Terni steel works and the iron mills of San Giovanni di Val d'Elsa, of Volbarno. There are various kinds of lignite to be found in Italy, the two principal ones being "lignite xiloide" and "lignite picea" (pitchy), or "schistosa." This latter kind is the purer, as it contains a smaller proportion of earthy substances and is drier.

ZÜRICH, 16TH JUNE, 1891.

AN EIFFEL TOWER FOR MOUNT PILATUS.—A scheme has been proposed for the erection of an Eiffel Tower on the summit of Mount Pilatus. The proposed tower is to have a height of 918ft., so that a splendid view of the Alps may be obtained. The tower is to be of steel, and be composed of two open-work cylinders.

SWISS RAILWAYS.—The Railway Department of the Swiss Government has issued a circular letter to the various branches of the Swiss Railway Union, directing attention to the growing importance of standard methods and appliances in the railway service, and to the good results which have already been achieved by their partial adoption. In the circular prominence is given to the desirability of uniformity in practice among the different railways, and the officials are requested to take the matter under consideration, and to determine upon proper resolutions with this end in view.

ELECTRIC LAUNCH ON THE LAKE OF ZÜRICH.—The first electric boat built on the Continent was launched last month on the Lake of Zürich. It has been built by Messrs. Esscher & Wyss and the Oërlikon Maschinenfabrik. It attains a speed of six miles per hour, and can run five or six hours with one charge of the fifty-six secondary cells carried.

NEW YORK, 6TH JUNE, 1891.

FUEL GAS FOR DOMESTIC USE.—The manufacture of fuel gas for domestic use in Terre Haute, Ind., is said to be a commercial success, the cost to consumers being about one-half the cost of hard coal. The gas is made from crude oil, and the company owning the plant is preparing to largely extend its mains.

NATURAL HOT WATER SUPPLY.—The Water Company at Boise City, Idaho, has two artesian wells each about 400ft. deep, discharging over 1,000,000 gallons of water per day. The water is reported to have a temperature of 180° Fahr. It is proposed to bore another well, so that the water may be used for bathing purposes.

LARGE MACHINE TOOLS.—The Universal Radial Drill Company has recently completed a pipe facing machine built for the Addyston Pipe Works, which is of 60in. swing, double-headed, and will take in between the heads a length of pipe 17ft. long, which is held stationary as in cylinder boring, while the heads carry swinging arms provided with sliding tool rests to do the facing.—Messrs. Robinson, Rea, & Co., of Pittsburgh, have completed two casings for rolling machines to be used at the Carnegie Armour Plate Mills, at Homestead, Pa. Each casing is in one piece, and weighs 90,000lb. One of the Pennsylvania gun trucks, with a carrying capacity of 100,000lb., was used in the transportation of the mammoth piece of iron. These trucks have 16 wheels, and are used exclusively for this kind of work. The largest crane at the foundry had only a capacity of 25,000lb., but by lifting one end at a time the big casting was placed in position on the car.

AWARD.—Mr. Henry M. Howe, of Boston, Mass., has been awarded a prize of £100 by the Société d'Encouragement pour l'Industrie Nationale, of Paris, for his treatise on "The Metallurgy of Steel," which was noticed in *Industries*, Vol X., page 112.

LARGE MARBLE COLUMNS.—The Vermont Marble Company, of Rutland, Vt., has recently made six marble columns 19ft. 7in. long, and 2ft. 10in. in diameter. They are each made from one solid piece of marble, turned in a lathe, and are said to be the largest ever turned out in the United States. They are for use in the construction of Whig Hall, Princeton College.

STEEL WIRE.—It is reported that the Washburn and Moen Works, of Worcester, have after many experiments brought out a process whereby steel wire can be made so that its ductility is equal to that of copper wire.

PHILADELPHIA, 5TH JUNE, 1891.

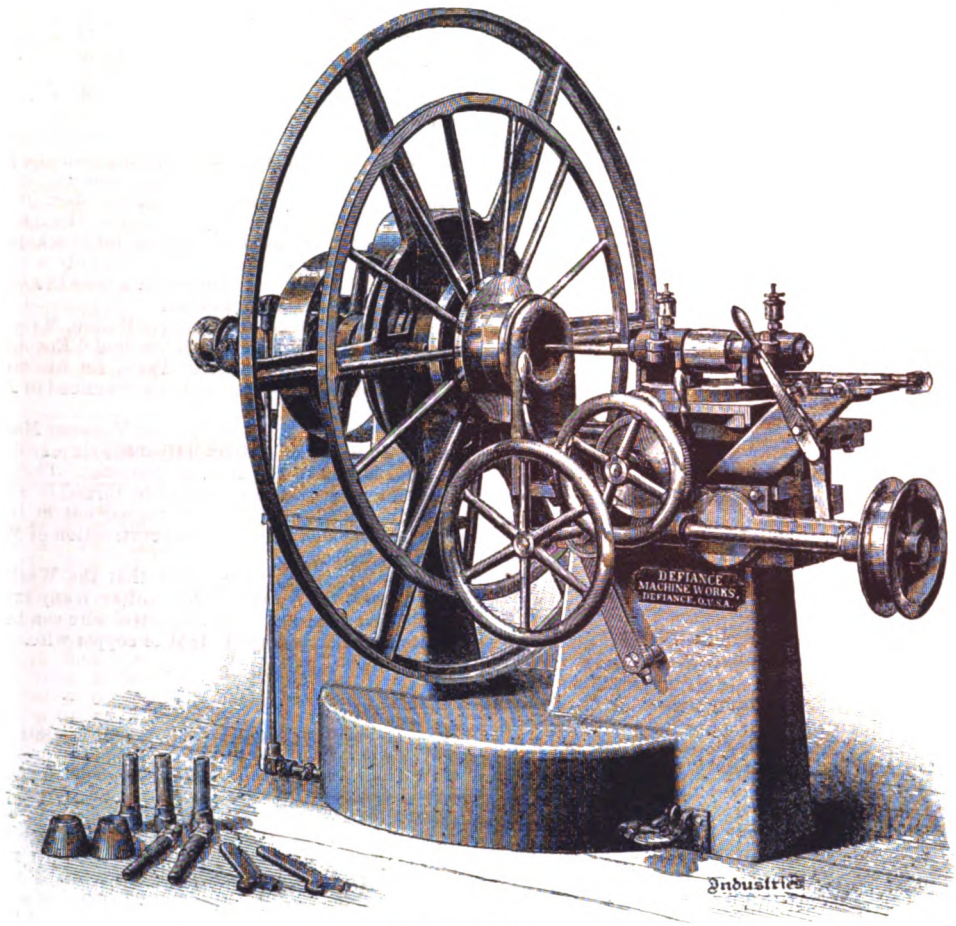
CRUISER "No. 13."—Tenders have been opened by the Navy Department for the construction of the protected cruiser "No 13," for which provision was made by the last Congress. The vessel is to be similar to cruiser "No. 12," and equipped with one 8in., two 6in., and a number of smaller rapid-firing and machine guns. She is designed to make, in an emergency, a speed of 22 knots, so as to enable her to capture or to escape from the pursuit of any vessel now afloat. The vessel is to be fitted with three triple-expansion engines, each driving a separate screw propeller. The tenders received were as follow:—Messrs. Wm. Cramp & Sons, of Philadelphia, £549,000; Bath Iron Works, of Bath, Maine, £538,000; Union Iron Works, of San Francisco, £558,600. The limit of cost fixed for the cruiser by Congress is £550,000, and a bounty of £10,000 for every ¼ knot in excess of 21 knots per hour developed by the cruiser on her trial trip.

IRON AND STEEL WORKERS.—The annual convention of the Amalgamated Association of Iron and Steel Workers has been opened at Pittsburgh. The wage committee has decided to fix the rates for puddling, heating, and rolling, and for catching in bar mills, at the same amount as during the past year—viz., £1 2s. and 2s. 11d. per ton, and five-eighths the product respectively. The outlook for the year is not particularly good, but it is believed that the manufacturers will not attempt a reduction.

RESUMPTION OF WORK AT COLLIERIES.—After being idle for six months the Exeter Colliery, of the Lehigh Valley Coal Company, will resume operations, giving employment to several hundred workmen. The Exeter Colliery is situated at West Pittson, and is one of the largest in the anthracite coal fields. It is thought probable that more of the collieries of this company which are now idle may resume work shortly.

ANOTHER "STANDARD OIL" PURCHASE.—It is announced from Newark, N.J., that the McKirgan Oil Company's property has been transferred to the Standard Oil Company. The property was valued at £40,000.

REDUCTION IN THE PRICE OF ALUMINIUM.—A reduction in the price of aluminium to 2s. 0½d. per pound is announced from Cincinnati. The reduction is on metal produced in unlimited quantities by a Newport aluminium company.



THE GUNS OF THE "VESUVIUS."—From the official report of the test of the guns on the dynamite cruiser "Vesuvius," it appears that these guns were not as unsatisfactory as was at first stated. The report states that the accuracy of fire of the starboard gun was good, and that the middle and port guns could not be criticised, since the valves were not in good working order. The Navy Department has ordered that the Board shall meet and prepare a programme of such further tests as they shall recommend.

PEARL BUTTON MANUFACTORY.—Another new industry which has come into existence here since the passage of the McKinley Act is the manufacture of pearl buttons. Since the decision that pearl blanks are subject to duty as manufactured buttons, there has been a vigorous movement to erect a large button factory in the vicinity of this city. The company proposes to employ about 2,000 hands, and has decided to employ American workmen only.

AUTOMATIC WHEEL BOXING MACHINE.

CONSTRUCTED BY THE DEFIANCE MACHINE WORKS, DEFIANCE, OHIO, U.S.A.

GENERAL VIEW.

AUTOMATIC WHEEL BOXING MACHINE.

THE accompanying illustration, which is reproduced from our contemporary, the *American Machinist*, represents a new machine made by the Defiance Machine Works, Defiance, Ohio, U.S.A., for the purpose of boring out wooden hubs of wheels for the reception of the sleeve, commonly called the "box." The wheel is centred by a plunger, which is forced forward by a spring, this plunger being hollow and of a conical form internally, so that, as it comes against the end of the hub, the wheel is centred. The felloe is, at the same time, trued sidewise by coming against the radial arms shown, and the wheel is driven by the two revolving padded discs, which bear upon the spokes near the hub, the outer one of these being held in place by pressure brought upon it by a lever, and which runs upon a bearing composed of forty §in. steel balls, to reduce friction. The time occupied in thus chucking the wheel is not over five seconds, and upon the machine being set in motion the wheel is revolved at 200 revolutions a minute, while the cutter, which makes 5,000 revolutions, is automatically fed through the hub on a line which conforms exactly to the outline of the box which is to be fitted. This is secured by the use of a former, which is placed at the back of the slide, by which the cross slide is moved at the proper rate, as the tool advances, to make it follow the desired outline. The feed is automatically thrown out at the completion of the boring. The machine is carefully designed and built, and provided with liberal bearing surfaces, and constitutes, we believe, a new departure in the manner of doing this work, and one which will conduce very much to greater accuracy and rapidity of work, as the appliance is capable of turning out 600 wheels per day. Provision is also made for cupping both ends of the hub at the same time to any size and shape.

NOTES ON PATENT LAW.

VI.

(*Continued from page* 568.)

WE are now in a position to summarise the law as to specifications apart from claiming clauses, and perhaps cannot do so better than by taking a supposititious case and applying the principles already laid down to the preparation of sample specifications (Provisional and Complete).

A sufficiently apt illustration lies ready to hand in James Watt's great invention of the steam engine condenser, which was the subject of much argument and an elaborate judicial decision in the year 1795. One of the judges who gave judgment in that case drew up what he conceived to be a sufficient specification of that invention in the following terms:—"Now the specification of such a discovery seems to consist in nothing more than saying to the constructor of a 'fire engine,' 'for the future condense your steam out of the body of the cylinder, instead of condensing it within it, put something round the cylinder to protect it from the external air and to preserve the heat within it, and keep your piston air tight without water.'" Throwing this substance into the modern and official form, we should obtain something like the following documents:—

PROVISIONAL SPECIFICATION.

Title. Improvements in Steam Engines.

Name and Description of Patentee. I, James Watt, of Glasgow, in the County of Lanark, Engineer, do hereby declare the nature of this invention to be as follows—that is to say, it

Description of the Nature of the Invention. consists in causing the steam which is used in the cylinder for the purpose of propelling the piston to be condensed in a separate vessel, and in preventing as nearly as possible any condensation of such steam from taking place within the cylinder by protecting the outside of the cylinder from contact with the external air or other cold bodies, and putting round it a suitable vessel or covering with this object, and also with the object of reducing the amount of radiation and consequent loss of heat to a minimum, and furthermore, in using as a packing for making the piston steam tight within the cylinder some suitable substance less absorbent of heat than cool water.

JAMES WATT.

Dated this 19th June, 1891.

It will be observed that we have here departed in several particulars from the sketch given by Chief Justice Eyre in his judgment. In the first place, instead of casting the specification into the form of injunctions addressed to a workman, we have thrown it into the literary form of a description of the invention. This the Patent Office prescribes. Then the specification commences with a title which serves to indicate the class of "manufactures" to which the invention relates. This also is a statutory requirement, and it is important that the title should be correct, although it will be observed that it may be expressed in the most comprehensive terms. Pursuing the text, we remark in the next place that the patentee does not here strictly explain the *object* of his improvements. It is very common practice to open with such an explanation—for instance, "The object of my improvements is to economise the fuel consumed in steam engines" would have been a perfectly proper commencement of the above specification; but it is more strictly in accordance with the official form not to do so, and, as we have already remarked, danger lurks in every supernumerary word of a provisional specification. When, however, the invention is an application of well-known principles, and consists in some comparatively small modification of existing mechanism, it is often by no means a supernumerary statement which sets out the purpose of the improvements with some precision. If there is likely to be any difficulty in disentangling the new matter from the old, a statement of that sort may materially assist the interpretation of the claims. But in the present case the improvement was a revolutionary one, and no difficulty in defining the novelty could possibly be apprehended. It is therefore safe, and consequently best, to follow the strict form, and go straight to the nature of the invention without any preliminary discussion of its objects.

The description itself is expressed, it will be observed, in the widest possible terms. The principle of separate condensation is clearly enunciated, and its consequences are followed out to the point of indicating, as by means of a verbal diagram, the nature of the several alterations that will have to be made in the mechanism for the purpose of giving effect to the principle. But there the description stops. Not a word is used that could limit the patentee to any particular mode of effecting these changes, and according to our existing law—which has grown up since James Watt's time—the patentee is entitled during his nine months of provisional protection to work out the details of his invention as so sketched out, and to get the benefit as a patented improvement of any novelty which he may thereafter disclose in his complete specification provided only that it is covered—not necessarily indicated—by the comprehensive language of the provisional specification.

We pass now to the complete specification which may be supposed to be founded on the foregoing provisional. It would be entituled in the same way, and the title would be followed, as in the provisional, by the full name, address, and description of the *applicant*—for by the name applicant the future patentee is known at this stage in the proceedings; the meaning, of course, is applicant for letters patent. These, therefore, need not be set out again, and we shall merely indicate them in the following specimen:—

COMPLETE SPECIFICATION.

Title (*as in provisional*).

I, James Watt (*&c., as in provisional*) do hereby declare the nature of this invention and in what manner the same is to be performed to be particularly described and ascertained in and by the following statement—that is to say, it consists (*&c., repeating the provisional specification*). . . . .

The better to make my meaning clear, and by way of illustration, I will proceed to describe a steam engine constructed and worked according to my improvements by the aid of the accompanying drawings, of which

Fig. I. is a front elevation.

Fig. II. is a section through the line 1——1 of Fig. I.

Fig. III. is &c., &c.

(*Here follows a precise description of the drawings*).

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is,

1.

2. &c. (*Claims to be discussed hereafter*).

JAMES WATT.

Dated this day of 1891.

It will be observed that the introductory passage here differs materially from that in the provisional specification, inasmuch as it adds to the undertaking to declare the nature of the invention a further undertaking to describe it particularly and ascertain it, and also to describe in like manner and ascertain "in what manner the same is to be performed." Still the nature of the invention has to be declared, and if the terms of the provisional specification amount to a sufficient declaration of its nature, it is well to incorporate them here. All necessary particularity will be supplied by the description of the drawings, and, therefore, the generality of the language of the provisional specification does not unfit it for this place.

In the description which follows care should, of course, be taken *to exhibit every feature* of the invention. Sometimes it is necessary for this purpose to show two or more modifications of the thing described in general terms. But it is idle to multiply figures and augment the description for the mere purpose of exhibiting *the same feature* under various *forms*. For example, in the supposed case the condenser might be constructed either as a still-worm or as a chamber occupied by baffle plates

Digitized by Google

or probably in any one of half a dozen other forms. But nothing would be gained by elaborating the specification in this way. One form of condenser, if effective for the purpose, would exhibit this feature of the invention as well as a hundred; therefore, the other ninety-nine would be mere surplusage. But, on the other hand, the draftsman should be careful to omit no single feature from his detailed description. It matters nothing to what dimensions this principle expands the specification. All necessary drawings and all necessary description must be given to exhibit everything essential to the effective working of the improved parts, and every detail on which the inventor means to rest a claim. Thus, in the given case, not only should the separate condenser be shown, but also the necessary details for working it; not only the steam jacket, but also the mode of keeping it supplied with steam; not only the improved packing for the piston, but also the way of applying it. Of course, these subordinate parts need not necessarily be described with any minuteness. If no claim is to be made to them, and no difficulty is presented in their construction or by their adaptation to the engine, they may be dismissed with a word, but the danger of describing new parts without including in the description old connections would be that of describing inadvertently new parts that could not work. This, if it happened, would destroy the patent irremediably, since no amendment of the specification could be permitted which would have the effect of so materially altering its subject matter.

These hints will probably enable the reader to form a better impression of what is required by way of description than an exemplification would, and, as that could not possibly be of use in any case arising at the present time, it has been omitted here. We pass now to the claims—a subject which must be reserved for our next article.

(To be continued.)

THE SILK ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The third annual dinner of the above Association was held at the Freemasons' Tavern, Great Queen Street, London, W.C., on Wednesday, the 17th inst., and was presided over by Lord Mashamshire (Mr. S. Cunliffe Lister, of Manningham), who has recently been raised to the peerage. There were also present:—Mr. Woodall, M.P.; Sir Philip Cunliffe Owen; Mr. Thomas Wardle, F.C.S., F.G.S., the President; Mr. Piggott, Secretary of the Association, and Mr. Reynolds, Secretary of the Manchester Technical School. The Chairman, in response to the toast of the Houses of Parliament, gave an account of the progress of the silk industry since his connection with it. He explained that after a struggle of several years he managed to produce a machine for combing silk waste, which had hitherto been a practically useless product of the silk industry. This waste he once bought at 8d. per pound, and, after being treated by his machine, it was retailed at the handsome price of 24s. per pound. Mr. Woodall urged that Free Trade principles, which at present appeared to handicap the silk industry of this country, would at length prove beneficial to it. Mr. Reynolds urged very forcibly the claims of technical education, and recommended that all students of spinning and weaving should also take up the study of art. He referred to the efforts made by the German nation as regards technical education, and stated that during a recent visit to a weaving school in Rhenish Prussia he discovered several students from Manchester, who were paying four times the fees paid by the German students for the privilege of studying there.

SHIPBUILDING NOTES.

The last of the three steam hopper barges constructed by Messrs. Wm. Simons & Co., Renfrew, for the Corporation of Preston has been tried on the Clyde with very satisfactory results. The measured mile was run at Skelmorlie, the mean speed obtained being about 10 miles per hour, which is in excess of that contracted for.

On the 6th inst. the Tyne Iron Shipbuilding Company, Ld., of Willington Quay-on-Tyne, launched the steel screw steamer "Cape Comino," which has been built to the order of a local firm. The vessel is of the following dimensions, viz.:—Length, 300ft.; breadth, 38ft. 8in.; depth, 23ft. 2in.; and is to class 100 A1 at Lloyd's. This vessel has water ballast fitted right fore and aft on the cellular system. The engines, which are to be supplied by Messrs. Wigham Richardson & Co., are of the triple-expansion type, having cylinders 23in., 37in., and 62in., by 42in. stroke, and working at a pressure of 160lb.

On the 6th inst. the steamer "Ibex," which has been built by Messrs. Laird for the Great Western Railway Company, was launched from the Birkenhead Ironworks. The vessel is intended to take part with the "Lynx," "Antelope," and "Gazelle," in the service between Weymouth and the Channel Islands. The "Ibex" is a steel twin-screw steamer of 270ft. in length, 32ft. 6in. beam, and 15ft. 6in. depth, and is about 1,380 tons B.M. The machinery, which is being constructed by Messrs. Laird, will consist of two sets of engines of the triple-expansion type, driving twin screws, and designed to propel the vessel at a speed of about 19 knots per hour.

On the 6th inst. the Naval Construction and Armaments Company, Barrow, launched from their shipbuilding yard the steel screw steamer "Indianapolis," for Messrs. James Little & Co., shipowners, Glasgow. Her dimensions are:—Length, 278ft.; breadth, 42ft.; depth, moulded, 21ft.; with a displacement of about 4,800 tons on a loaded draught of 19ft. 3in. She will class 100 A1 at Lloyd's. Water ballast is carried in a cellular double bottom, and the hull is divided into four water-tight compartments. Messrs. Westray, Copeland, & Co., Barrow, will fit the vessel with a set of triple-expansion engines.

On the 8th inst. Sir Raylton Dixon & Co., Middlesbrough, launched from the Cleveland Dockyard the large steel screw steamer "Dictator," which has been built for Messrs. Thos. and Jas. Harrison, Liverpool, of the following dimensions:—Length, over all, 378ft. 6in.; breadth, 45ft.; depth, moulded, 31ft. 3in., with a deadweight capacity of about 6,000 tons. The engines will be fitted by Messrs. T. Richardson & Sons, Hartlepool, with cylinders 24in., 40in., and 61in., by 51in. stroke.

Notices of Meetings.

NEXT WEEK.

Royal Institute of British Architects.—Monday, June 22nd, at 8 p.m. Presentation of the Royal Gold Medal.

Society of Architects.—Tuesday, June 23rd, at 7.30 p.m. Annual general meeting.

Chemical Society.—Thursday, June 25th, at 8 p.m. Extraordinary general meeting.

PRICES CURRENT, 17th June, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues firm. Chili bars have steadily advanced in value during the last few days, current quotations being 12s. 6d. to 15s. higher than in our last report. To-day's prices are £55 15s. to £56 5s. cash, with firm market. Manufactured firm at £66 to £67, "strong."

Tin: Changeable. To-day's market reported firmer.

Lead: Steady, with small business; values unchanged.

Spelter has advanced considerably, owing to improved demand on the Continent. Stocks are very small, and the producers have sold their make for some months, so that prices are likely to advance further.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: There is no change in caustic soda or bleaching powder, demand being good and prices steady, but the inquiry for soda ash is rather slower. Crude carbolic is quite neglected. Benzoles also are flat. Creosote is active. Sulphate of ammonia is quoted lower, but little business is being done. Sulphate of copper has receded slightly on spot, but has more attention for forward delivery. There is more inquiry for borax. Sulphur is more plentiful.

HOME INDUSTRIES.

LONDON, 18th June, 1891.

The Money Market.—Money continues cheap and plentiful, the shipment of over a million of gold to Russia making no impression, as it had been fully expected for some time. Gold continues to arrive at the Bank from other quarters in large sums, and thus rates are kept very easy. Despite the cheapness of money, business on the Stock Exchange is on an exceedingly small scale. American railways showed signs of recovering tone and strength, but the weakness of one or two stocks largely held in England, notably Denver Preferred and Louisvilles, owing to rumours of diminished dividends, has deprived this market of its slowly returning vigour. Home railways have fared no better—rather worse, indeed—the returns of those lines which publish periodical net revenue statements being such as to point in the direction of shrunken dividends. Foreign securities continue firm, and South Americans show an improvement. Among miscellaneous shares home breweries have shown a weaker tendency. The mining market looks a trifle better, but business there is still very dull.

The Junior Engineering Society.—On the 30th ult. a large party of members of this Society availed themselves of the opportunity kindly afforded by the locomotive superintendent, Mr. W. Kirtley, for visiting the locomotive, carriage, and waggon works of the London, Chatham, and Dover Railway, Wandsworth Road. They were received and shown over by the manager and other members of the staff, by whom the numerous features of interest were pointed out and fully explained. The boundary wall encloses an area of about 18 acres, and the relative positions of the shops are conveniently arranged with a view to the systematic execution of the work. In the sawmill a very complete plant of modern wood working machinery was shown, for the treatment by sawing, planing, mortising, and tenoning of the rough log for the purpose of making the finished parts of the carriages and waggons, which were subsequently seen in various stages of construction. In the locomotive department, the boiler-makers', coppersmiths', erectors', and smiths' shops; the fitting and machine, and the pattern, wheel, and heavy tool shops were each inspected. The running shed, which is situated immediately outside the works, was also visited. It covers an area of area of 5,906 square yards, and will hold ninety engines. Types of the company's various classes of locomotives were here seen.

The Whitehead Torpedo at the Naval Exhibition.—It has at last been managed to successfully launch the Whitehead torpedo in the lake at the Royal Naval Exhibition. The torpedo is launched from a torpedo tube similar to that used on board a man-of-war, in a depth of 5ft. of water and with a range of about 70 yards. When fully charged, the torpedo contains about 200lb. of gun cotton; it travels at a rate of 30 miles an hour, and at any pre-arranged depth from 10ft. to 17ft. under the surface. The torpedo has, however, been so adjusted that it runs in the lake at the Exhibition without causing injury to the public, the lake, or the machine itself. The torpedo is discharged by a charge of 3oz. of powder, exploded in the rear end of the tube by electricity from the torpedo house. The motive power is compressed air, which is carried at a pressure of 1,500lb. on the square inch. The charge is exploded on coming into contact with any object. A light carried on the nose of the torpedo enables its location to be clearly seen, and so assists in its ultimate recovery. The arrangement on the lake is that the torpedo is discharged in the ordinary way, and runs under the target, where an obstacle is so placed as to cut off the compressed air from the engines, and also to nearly "bring up" the torpedo. A small charge is exploded when the torpedo comes into contact with this obstacle under the target, which represents in a small measure what would happen if the real charge of 200lb. of gun-cotton, 400 times as powerful, was fired.

The Society of Engineers.—On the 17th inst. a visit was paid by the Society of Engineers to the Linde British Refrigeration Company's Ice Works at Lower Shadwell and the City and South London Electric Railway Company's Depot at Stockwell. The ice works at Lower Shadwell, which are said to be the largest in Europe, if not in the world, were completed in 1889, and are capable of producing about 120 tons of ice per day, and of storing about 500 tons of frozen meat.

The Society of Arts.—On the evening of the 17th inst. a conversazione of this Society was held at the South Kensington Museum, among those present being Sir Richard Webster, M.P. (Chairman), Lord Bramwell, Sir. P. Cunliffe Owen, Sir R. Rawlinson, Sir F. Abel, and a large number of distinguished members and guests. During the evening selections of music were played by the bands of the Grenadier Guards and the Scots Guards, and a concert of ancient English music was given in the lecture theatre.

The Sanitary Institute.—An examination for local surveyors was held on the 5th and 6th inst. by the Sanitary Institute. Questions were set in writing on the 5th inst., and a *viva voce* examination took place on the 6th inst. Eleven candidates presented themselves for examination, of whom eight were certified to be competent, as regards their sanitary knowledge, to discharge the duties of local surveyor.

Change of Address.—The office of the Junior Engineering Society has been removed from 64, Reedworth Street, Kennington Road, S.E., to 29, Fentiman Road, Clapham Road, S.W.

MANCHESTER, 18th June, 1891.

Mining Statistics.—The returns furnished by the Inspector of Mines for the North and East Lancashire district show that there were 280 coal and 23 metalliferous mines in the district. The production was 10,607,977 tons of coal, valued at £4,287,000, and 110,570 tons of fireclay, valued at £16,585. There were 55 fatal accidents, of which the majority occurred between 11 a.m. and noon.

Town Gardening.—As a corollary to the researches of the Town Gardening Committee of the Field Naturalists' Society into the condition of the air in Manchester a grant has been made by the Royal Society to assist in making further inquiries. The work is being carried out in connection with the Royal Horticultural Society, who are pursuing the subject in London, and the observations are to include investigations into the bacteriology of the air, with a view to ascertain the conditions of infectious and other diseases. Similar experiments are being made in Leeds and Liverpool.

Paper Makers' Hours.—The movement for shorter hours on the part of the workers in paper mills is extending. It is stated that thirty-four of the Scotch mills have already adopted the proposed stoppage on Saturday at 2 o'clock. Meetings have been held at Darwen, Radcliffe, and Bury, at which the resolution to insist on a stoppage on Saturday at 1 o'clock was unanimously agreed to.

The Half Time Movement.—At a meeting of the Manchester District Union of Elementary Teachers, recently held, a resolution strongly supporting the limitation of the age at which children can be employed was passed. It was insisted on that the much higher standard of efficiency required by the Education Department rendered it absolutely necessary that children should remain all their time at school to a later age.

The Engineering Trades.—There are a number of indications in some of the departments of engineering of a waning trade. Orders are more difficult to get, and prices are being complained of. At the same time, there is nothing acute in the situation, as old contracts continue to occupy the various works to a fair extent. In the locomotive trade signs of falling off are apparent, and the tool trade is by no means so busy as a few months ago. Cotton machinists, however, are still fully and actively engaged, and in this department there is still new business to be had. Messrs. W. H. Bailey & Co., Ld., are very busy in their pump department, especially in the department devoted to a pump specially constructed for pumping out deep mines. They have also had a large order for testers of various kinds from India. One or two of the machinery export houses are getting some good contracts for machinery, but, generally speaking, there is considerably less activity than formerly. The contract for the shafting, rope pulleys, hangers, pedestals, pulleys, gearing, and other fittings for the new mills for the Fustian Cutting Machine Company, Ld., of Ordsal Mills, Manchester, has been secured by Messrs. Geo. Richards & Co., Ld., Broadheath, near Manchester.

The Linen and Jute Trades.—The condition of trade both in the home and shipping branches continues to be most unsatisfactory. As an example of the difficulties against which merchants have to contend it may be mentioned that the Brazilian trade is affected adversely by the action of the Government in insisting upon duties being paid in gold. Importers have protested, but in vain, and, according to advices just received here, they now threaten to abstain from withdrawing goods from the custom-houses until the obnoxious order is rescinded. The rate of exchange is adverse to business with South America. In the home trade special efforts have been made to diminish the amount of stocks this week by means of clearing and other sales. The amount of goods in the hands of retailers is said to be above the average, but warehousemen are slightly better off in this respect. Under existing conditions, it is not easy to see how employment can be found for so many men as were at work twelve months ago. Prices, however, remain firm in all branches, and the situation is strengthened by the fact that French spinners maintain a very firm attitude when quotations are asked for delivery to English buyers. Trade with the United States has fallen off. In handkerchiefs there has not been such a large demand here for machine embroidered descriptions, which are being turned out by St. Gall houses in extensive quantities, but in Glasgow and in New York they are said to meet with a good sale, to the injury of the Irish hand embroiderers. Irish firms can only escape the threatened danger by resorting more largely to the use of the Swiss embroidery machine.

GLASGOW, 18th June, 1891.

Pig Iron.—The dealing in pig iron during the past few days has been very small. The price is thus purely nominal, and any considerable operation on either side of the account would necessarily seriously affect it in one way or in the other.

Engineering.—A new rotary engine has been brought out by Mr. A. F. G. Brown, of Swindridgemuir, Dalry, Ayrshire. The engine has been made by Messrs. John Lang & Sons, of Johnstone, and it is claimed that it is more economical than other engines of this type already in the market. The steam inlet valves of the cylinder bear tightly against the piston, the cavities in which are so adjusted that the valves are opened by the pressure of steam behind them at the proper moment for the admission of steam, while the exhaust effects the automatic closing of the valves. The cylinder is supplied with steam twice during each revolution. The diameter of the cylinder employed in the original engine is 10¼in. by 8½in. A series of indicator diagrams was taken by the McInnes indicator, and it is said that this is the first time the indicator has been used to indicate a rotary engine. The power indicated was 29 h.p., with a pressure in cylinder of 80lb. per square inch. The tests were made by Professor Jamieson, of the Glasgow and West of Scotland Technical College.

British Association in 1892.—The British Association meeting in Edinburgh, in 1892, will be presided over by Sir Archibald Geikie, the vice-presidents being Lord Provost Boyd, the Marquis of Lothian, Earl Rosebery, Lord Kingsburgh, Principal Sir William Muir, and Sir Douglas Maclagan. The meeting will begin on September 29th, 1892.

Scottish Railways.—On the 16th inst. the Select Committee of the House of Commons found the preamble proved of the Caledonian, Lanarkshire, and Dumbartonshire Railway Bill. The new railway will start from Stobcross, Glasgow, with a junction to the line from Buchanan, and will pass near to the existing North British Railway by Clydebank and Bowling to Dumbarton. The present Vale of Leven line runs from Dumbarton on the west side of the River Leven. The new line will go on the east side by Jamestown and Cartocharan, terminating on the shore of Loch Lomond, near the River Endrick. The district at the extremity of the line is not at present served by a railway. The practical passing of the measure will bring about competition between the Caledonian Railway and the North British Railway for the traffic in the Vale of Leven. In finding the preamble proved, the Committee imposed upon the Caledonian Company the obligation to facilitate the extension of the Yoker line to the North British line at Dalmuir, and to subscribe to the capital of the West Highland Railway to the extent of £40,000. Besides invading Dumbartonshire, which has hitherto been closed to its operations, the Caledonian Railway is attempting to secure a footing in Fifeshire. The Bill is still before the Committee.

Security Company.—The first public safe was opened in Glasgow on the 16th inst. by the Security Company. The safe is situated on the ground floor and basement of the Stock Exchange Buildings in Buchanan Street.

(From our own Correspondents.)

LIVERPOOL, 17th June, 1891.

The Mersey Railway.—Although the Prince of Wales travelled in a through carriage from Chester to James Street Station in Liverpool to inaugurate the opening of the tunnel six years ago, it was only on the 15th inst. that this through connection was opened to the public, and a regular service of trains initiated. After great opposition, and in face of enormous difficulties, the directors have successfully pushed forward the enterprise, and by this new connection with the main line of the Joint Railways their financial troubles will most probably be swept away. The previous development of the railway system and connections to the various favourite resorts in the Wirral peninsula has made the place more prosperous, and building operations are increasing very rapidly. As an inducement to people to live on the Cheshire side of the Mersey, the company propose to issue contract tickets at a specially low rate; these, no doubt, will be taken advantage of, and the Woodside Ferry receipts will suffer a still further reduction in consequence. The extension of the railway to the Cheshire lines system is approaching completion.

The Liverpool Water Supply.—The shield used in the construction of the tunnel under the Mersey was, last week, about 95ft. from the Lancashire side, a distance of 10ft. 3in. having been driven in one week. A horizontal air-lock will be in use this week, when it is expected that more rapid progress will be made. A pipe between Norton and the Mersey has been found to be split, and this has detained the washing out of the temporary pipes in preparation for the continuous supply.

Liverpool Engineering Society.—The following summer excursions have been arranged for members of this Society:—On the 27th inst. the Thirlmere Aqueduct will be visited, on August 3rd the Dore and Chinley Railway (Midland Railway, Derbyshire), and on September 12th the Norton Water Tower.

LEEDS, 17th June, 1891.

The Iron and Steel Trades.—There is no increase of business in the iron trade. The majority of makers continue to be short of orders, and the mills are working irregularly. Although prospects appear to be very uncertain, there is little chance of any reduction in prices. The price of fuel remains firm, and unless there is some reduction in price in this direction, it will be impossible for iron manufacturers to lower their prices. The activity is perhaps greater in the engineering branch than in the iron industry, engineers and makers of heavy machinery being still well supplied with orders. There is a hope that the present low prices may stimulate consumption, and lead to a better state of things. There is a fairly good inquiry for steel, although prices are reported to be not very remunerative, and manufacture of girders at the Leeds Steel Works is now in full operation.

Digitized by Google

THE COAL TRADE.—Considering the season, a good business is being done in coal for domestic use. There is a fair demand for locomotive and gas coal. Tenders received by the gas committee of the Leeds Corporation for a year's supply of coal show a reduction on the prices paid by the committee last year.

SHEFFIELD, 17TH JUNE 1891.

A NEW STEEL PROCESS.—On the 12th inst. the experimental open-hearth furnace at the Technical School melted its first charge, which was successfully teamed in the presence of many persons interested in steel manufacture. The plant throughout has been designed by Mr. B. H. Thwaite, C.E., but has been modified in some respects to meet the requirements of Professor Arnold, of the above-named institution. The designers hope to revolutionise modern methods of making high-class tool steels by removing all impurities from Swedish pig iron and retaining the precise amount of carbon necessary. The process, if successful, will certainly have an important bearing upon the future of the open-hearth process, and may transfer a considerable amount of our trade with Sweden to Sheffield firms.

LOCAL COMPANIES.—Messrs. John Brown & Co., Ld., of the Atlas Works, have issued a balance sheet for the year ending March 31st last, in which the directors say that the iron and steel trades are not in such a prosperous state as when they made up their last report, although their various departments have worked satisfactorily during the past year. The gross profit is £190,556 15s. 8d., or, after deducting interest on debentures and loans, £174,914 1s. A dividend at the rate of 10 per cent. per annum is declared; £88,000 is added to the reserve fund, which will thus amount to £200,000; and £21,461 15s. 8d. has been carried forward to next year's account. The retiring directors are Mr. John D. Ellis and Mr. H. D. Pochin.

GENERAL TRADE. Orders for railway material keep manufacturers well employed, although the pressure of work has somewhat diminished. Rolling mills and forges would be glad to have more orders. Engineers are only moderately well employed, as they depend solely upon local orders.

FUEL.—Fuel of all classes is still in good demand, although there is a decided falling off in household coal. Manufacturers expect soon to be able to buy engine slack for less than 8s. per ton.

LEICESTER, 17TH JUNE, 1891.

WOOL SPINNING AND YARN TRADES.—There is considerable lack of confidence prevailing in the local wool market, but prices are well maintained. There is a general feeling that the new clip when it comes into the market will not very materially affect prices, as the stocks of old wool are very limited and in few hands. It is believed that the stocks on hand are less than the average of many years past. Choice lots of short wool are wanted and skin wools sell fairly well. Good half hog and ewe wool of strong staple make are quoted at 23s to 24s. per tod. Choice lots, including good proportions of Shropshires, are at 24s. 6d. to 26s. 6d. per tod. Spinners are fairly well employed, but find competition very keen, and prices obtainable are not in proportion to the value of the raw material. Lambswool fancy and knitting yarns are in better request for prompt delivery. Cashmeres are moderate and cotton yarns flat.

HOSIERY TRADE.—There is a slight improvement in this trade, but the amount of business is under the average. More inquiries are being made for light fabrics. In heavy and medium goods there is more activity, and production is being enlarged to meet the anticipated demand.

BOOT AND SHOE TRADE.—This important industry is still in a very depressed state. Very few firms are busy, and the aggregate output is much under the average. There does not appear to be any prospect of immediate improvement. This quietness of trade seriously affects some of the smaller firms.

SWANSEA, 17TH JUNE, 1891.

LARGE VENTILATING FAN.—The Union Engineering Company, of Manchester, have built, to the order of the Cambrian Navigation Company, for their No. 3 pit at Clydach Vale, a Schiele's fan, which is stated to be the largest ever constructed, and is capable of giving out under favourable conditions half a million cubic feet of air per minute. The pit itself is also of exceptional dimensions, being 21ft. in diameter within the walling, and is the largest in South Wales. These collieries, which employ about 1,500 persons, are lighted by electricity both on the surface and underground.

INCREASED USE OF SAFETY LAMPS.—Mr. I. S. Martin, H.M. Inspector of Mines for the South-Western district, reports that the number of safety lamps used in his section now exceeds 9,400, whereas in 1875 there were only 1,755 employed.

CANNEL COAL IN FLINTSHIRE.—It is announced that Mr. Hopwood, of Pontybodkin, has made a valuable discovery of coal in Flintshire. He was working a small colliery when he struck a fine seam of cannel, which he has proved by borings to exist in great thickness under an area of about three miles. It is proposed to sink two shafts as soon as possible.

NOTICES AT STEEL WORKS.—In consequence of the falling off of orders for bars, owing to the impending stop month at the tinplate works, notices have been posted up at the Rhymney Iron Works to terminate the present contracts with the workmen, and to work on the "day to day" principle. It is also rumoured that the only blast furnace now working on the Rhymney side of the works will be shortly stopped, which will cause about 150 men to be out of work. Notices have also been posted up at the Briton Ferry Steel Works that all contracts will terminate on the 27th inst. The Elba Steel Works at Gowerton have already closed. A strike is now taking place at a tinplate works which is extraordinary under existing circumstances. The workmen at the Fairwood Tinplate Works, rather than work on the "day to day" system, have preferred to add another fortnight to their enforced idleness. This strike makes it evident that the men, as well as the masters, have been reaping great advantage from the recent heavy demand for tinplates.

CARDIFF, 17TH JUNE, 1891.

THE COAL MARKET.—The steam coal market continues firm, and there is no sign of weakness in prices. Best quality is quoted at 15s. 3d. to 15s. 6d. per ton; second, 14s. to 14s. 9d.; third, 13s. 3d. to 13s. 9d.; fourth, 12s. 9d. to 13s. Household sorts are dull. Coke finds a limited market at last week's prices. The iron and steel trades show no animation. Steel bars have fallen in price on account of the stoppage in the tinplate works. Rubio ore, first quality, realises 13s. per ton c.i.f. Cardiff and Newport, 50 per cent.

CARDIFF PHOTOGRAPHIC SOCIETY.—An International Photographic Exhibition, including photographic apparatus and appliances, will be held in the Public Hall, Cardiff, from 12th to 26th August next, during the visit of the British Association. All exhibits must be delivered at the Public Hall, Cardiff, on or before August 7th.

BARROW-IN-FURNESS, 17TH JUNE, 1891.

HEMATITE.—The market is again quiet in hematite this week. Orders are coming to hand very slowly from both home and foreign sources. The gradual reduction which has taken place in stocks week by week for a considerable time has been checked, and while last week stocks remained steady, this week they have been increased by 31 tons, and now amount to 139,574 tons. Prices have fluctuated somewhat during the week, and are now at 50s. per ton net cash for warrant iron, while makers are asking 51s. for Bessemer mixed numbers net f.o.b. There are 41 furnaces in blast, and 36 standing idle. Last year 45 furnaces were in blast.

STEEL.—There is a quieter business in the steel trade. The Siemens plate mills at the Barrow Steel Works have been stopped pending the laying down of new and powerful engines and the erection of a new light mill. In the West Cumberland district the steel works are indifferently employed. The West Cumberland works at Workington and the Moss Bay Steel Works, are short of orders, and the steel works of Messrs. Hampton & Facer, at Maryport, are doing only a small business. The Bessemer trade is not brisk, and makers are depending only on orders received some time ago.

IRON ORE.—Orders for iron ore are comparatively few, and business is slacker. Iron ore is quoted at 9s. 6d. to 9s. 9d. per ton net at mines. A cargo of iron ore is being shipped this week to New York.

SALT AND COAL.—It has been determined to develop on a large scale the recent discovery of salt on Walney Island, which is situated within the borough of Barrow. The salt is found within an area of about 10 square miles with a depth of the very best salt varying from 97ft. to 450ft. within 100 yards of the surface. It is proposed to raise every year and manufacture 150,000 tons of salt at Barrow, and the supply is considered by experts to be inexhaustible. In connection with this discovery of salt Mr. Russell is of opinion that a valuable bed of coal will be found underlying the salt deposit at a depth that will not be unworkable. A find of coal would be of immense importance to the industries of Barrow.

TUBULAR FRAME WAGGONS.—This week the Tubular Frame Waggon Company, Barrow, has despatched or shipped new waggons to the Waterford and Limerick, Great Northern of Ireland, Southern Railway of Spain, Aranco Railway of Chili, and the Great Northern Railway (England). The company have also under construction waggons for the Gas Company of Brussels, the German State Railways and the Italian Railways, the Tralee-Dingle Railways, and the Furness Railways. They are also preparing drawings for other railways, on which work will be commenced at once. The prospects of tubular frame waggon building at Barrow are good, and already orders are in hand to employ the works for over two years.

MIDDLESBROUGH, 17TH JUNE, 1891.

PIG IRON.—There was a large attendance at the weekly market on 'Change yesterday, but business was very bad. Indeed, most of the small quantity of iron that was sold was for sending into the warrant stores, a better price being obtainable for warrants than for makers' iron. The general quotations for makers' No. 3 Cleveland pig was 40s. per ton, but buyers generally would not pay more than 39s. 9d., and offered 39s. for August delivery. No. 1 was quoted at 42s. 6d., No. 4 foundry at 39s., and No. 4 forge at 38s. Local hematite is 51s. per ton for mixed numbers. For Cleveland warrants 41s. cash has been paid, and sellers are asking from 41s. 1½d. to 41s. 3d. per ton. A large quantity of iron has been sent into the public stores during the last few days, and the stock held by Messrs. Connal & Co. up to the 15th inst. amounted to 131,697 tons, an increase for the month of 6,128 tons.

MANUFACTURED IRON AND STEEL.—In the finished iron and steel trades prices are unchanged, and manufacturers say that they are very unprofitable. It is probable that at the present time further reductions in quotations would no more tempt consumers than the present rates do, and the loss would only be increased. Quotations are:—Common bars. £5 12s. 6d.; iron angles, £5 5s.; steel angles, £5 15s.; steel plates, £6; iron plates, £5 10s.; all less the usual 2½ per cent. for cash on the 10th of the month and f.o t. at works. Heavy steel rails are £4 10s., and cast iron chairs £3 per ton, both net, at works.

SHIPMENTS.—Shipments are falling off, and for last week only amounted to 14,840 tons, as against 21,580 for the week ending the 6th inst. The total shipments for the month up to the 15th inst. were 35,700 tons, as compared with 43,349 tons during the same period of May. Of the iron shipped this month 20,770 tons went to Scotland, 3,380 to England and Wales, and 11,550 tons to foreign ports.

ENGINEERING.—The first annual report of Messrs. Head, Wrightson, & Co., Teesdale Iron Works, South Stockton, which has just been issued, is very sasisfactory. The gross profit for the year ending April 30th was £33,531 19s. 5d. After providing for the payment of the directors and management, interest on debentures, and interest on purchase money to vendors, a dividend of 7½ per cent. per annum is recommended.

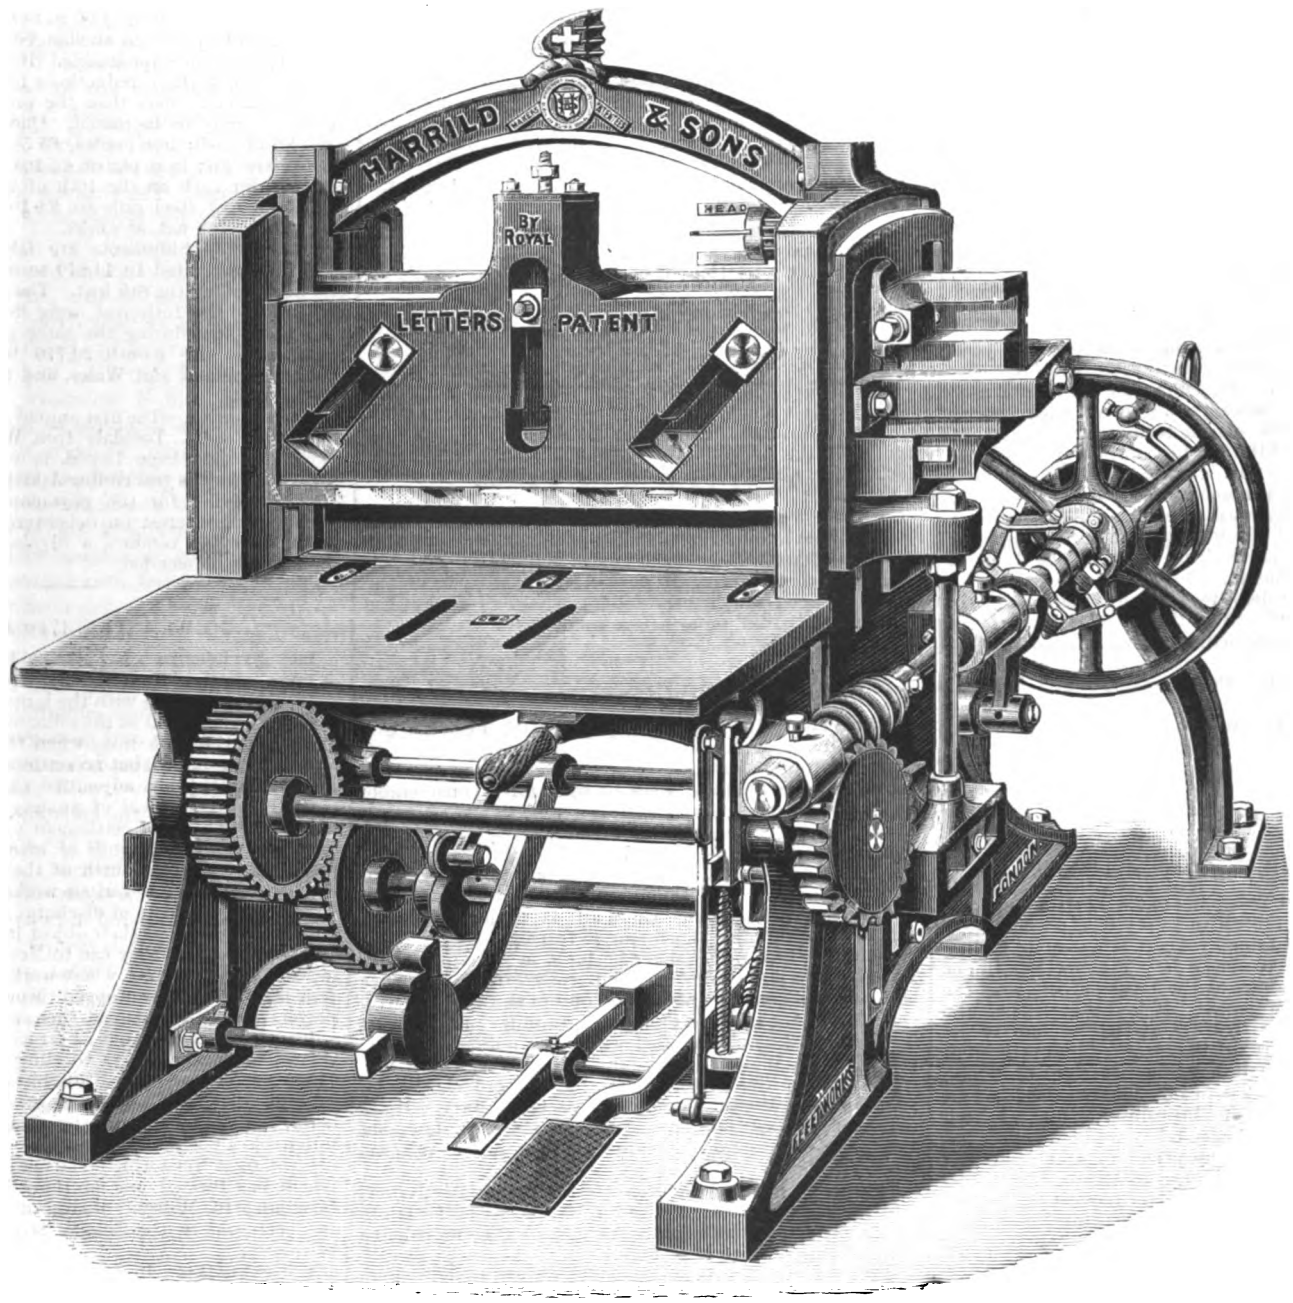
NEWCASTLE, 17TH JUNE, 1891.

THE FITTERS AND PLUMBERS' DISPUTE.—A conference of representatives from both these sections of workmen and employers connected with the larger engineering works in the district was held at the office of the Employers' Association on the 15th inst., when the questions in dispute were fully discussed, but no settlement having been arrived at, the meeting was adjourned till to-day. The matter is causing a good deal of anxiety in business circles, as, unless some basis of settlement can be found, a lock-out affecting many thousands of men must necessarily take place. Already one-fourth of the society men have been discharged from the various works, and an equal number have received notices of discharge for the 20th inst. The employers state that their object in discharging the men is to afford what aid they can to Messrs. Palmer's Shipbuilding and Iron Company, whose works have for several weeks past been practically stopped through the dispute. The employers having committed themselves to this policy, they will probably carry it out as far as may be necessary. The refusal of the engineers to allow the dispute at Messrs. Palmer's to be submitted to arbitration is the cause of the present crisis, which, so far as existing indications serve to show, can only be ended by their withdrawing from so untenable a position.

SALE OF A STEAMER.—The fine steamer "Port Augusta," which has formed one of the "Port" line of steamers, belonging to Messrs. Milburn, of London and Newcastle, has been sold to the Russian Steam Navigation Company, of Odessa.

ENGINEERING.—In the marine engineering establishments business is just now in a somewhat disorganised state, owing to the dispute respecting the apportionment of work. The locomotive works, however, are well employed, and at Messrs. Stephenson's establishment there is much activity. Messrs. T. Toward & Co., of the St. Lawrence Iron Works, have just carried out an extension of their establishment, which is expected to double the productive capacity. The firm are at present very fully occupied with the manufacture of tanks and boilers of a light description. There is now on view at the show rooms of Messrs. Allen & Robson, Dean Street, a new tube stopper, which is specially designed for stopping leaky tubes of the "Serve" type. The new stopper is said to answer its purpose admirably.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending the 13th inst. amounted to 111,890 tons, being a decrease as compared with the corresponding week last year of 7,313 tons. It is understood that the new coal staiths will be ready for use by the end of July.



DUNDEE, 17TH JUNE, 1891.

JUTE AND FLAX TRADES.—The prospects of the new jute crop are said to have suffered from a too copious rainfall, but the reports with reference to the crop do not appear to have affected the market. There is little business in new jute, and the prices of the old crop are adverse to sellers. Jute yarns are very firm, but transactions are limited, as the demand for fabrics is very small, and manufacturers find a difficulty in selling at remunerative prices. There is little demand for flax, either on spot or contract, and business is only for immediate wants. Flax yarns are quiet, and there is less business in linen, both on home and foreign account, but makers are still well employed.

IMPROVED PAPER CUTTING MACHINE.

CONSTRUCTED BY MESSRS. HARRILD & SONS, ENGINEERS, 25, FARRINGDON STREET, LONDON, E.C.

GENERAL VIEW.

NEW STEEL MAKING PROCESS.

AN interesting industrial event took place on the 12th inst. at the Sheffield Technical School, which was witnessed by members of the School Committee, students, and other gentlemen interested in steel manufacture. The company met for the purpose of witnessing the working of a new steel process due to Professor Arnold. The Professor conducted the operations, and the chief feature of the occasion was the getting out of the first heat from the new experimental open-hearth furnace which has just been completed at the school. The operation, according to our Sheffield correspondent, was very successful, the ingots teamed being of a composition never previously heard of in the history of steel. This process, which is the outcome of the researches recently made by Professor Arnold, opens up possibilities for the cheap and rapid manufacture of high-class steels which are likely to bring about a revolution in the present processes of manufacture. The process consists in practically removing the whole of the impurities from Swedish pig iron, with the exception of the exact proportion of carbon required for a given purpose, thus obtaining the ideal carbon and iron steel, homogeneous in structure and absolutely free from blowholes, these results being obtained without the presence of more than mere traces of manganese and silicon, and also without the use of iron ore. The average time occupied by this process in the conversion of a ton of pig iron into the highest class of steel yet made will be about three hours, the fuel used consisting of about half a ton of rough slack. The new furnace, together with the general plant, was designed to Professor Arnold's specifications by Mr. B. H. Thwaite, C.E., of Liverpool, and is intended to produce three tons of steel per day of 24 hours. The cost of the really necessary portions of this plant would, we understand, be no more than that of an ordinary twelve-hole crucible furnace. Much can hardly be said at present as to the capabilities of the process, but it is anticipated that the range of the metal produced will vary from what would be considered wrought iron to the hardest tool steel.

IMPROVED PAPER CUTTING MACHINE.

THE illustration given above represents the "Self-Clamp Trimming Machine" which has recently been introduced by Messrs. Harrild & Sons, 25, Farringdon Street, London, E.C. This machine possesses several important improvements over the ordinary guillotine machines. As we described at some length the various improvements which have been made in this machine in our "Abstract of British Specifications" of last week, it will only be necessary to refer briefly to the general features of the appliance. We have had an opportunity of witnessing the working of the machine, and can testify to the successful manner in which it carries out the various operations. The principal improvement embodied in it consists of an ingenious method of imparting the up-and-down motion to the knife beam with the object of doing away with counterbalance weights. These are usually adopted to prevent the knife frame and beam descending of their own weight when the machine is disconnected from the driving power or the brake has been applied. This is effected, in this case, by means of worm and spur gearing giving motion to slide blocks which move in vertical guides in the side frames of the machine. These slide blocks are in turn connected by rods to upper slides carrying the knife frame and pressure beam. The pressure beam moves in vertical guides, and the knife frame during the lower portion of its stroke moves in the inclined guides shown in the pressure beam, so that, by its oblique movement, the knife acts upon the paper with a drawing cut.

The clutch mechanism on the first motion shaft for stopping and starting purposes consists of a split clutch on the shaft, having projecting bosses, which enter corresponding holes in the fly-wheel, causing the wheel and clutch to rotate together. The clutch has flanges tapped to receive quick-threaded screw bolts, which, when given a slight turn by means of toggle levers connecting them with a sleeve on the shaft, cause the clutch to grip the shaft, the whole mechanism being rotated together. The knife is capable of withdrawal from the frame at the sides of the machine, instead of having to be lifted off at the front, as in the old machines.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 389, Strand, London, W.C.*

Offices for Publication:
358, *Strand, London, W.C.*

FRIDAY, 19TH JUNE, 1891.

THE GREAT SIBERIAN RAILWAY.

WE have several times given what information we could with regard to the proposal to construct a railway across Siberia, but hitherto the matter has been, to a very great extent, a matter of speculation. It has now, however, passed, not only into the region of practical politics, but also into that of practical engineering. That the immediate, and, indeed, the main reason for the construction of the line at the present time is a political one cannot, of course, be denied, and while it is no part of our province to discuss politics in a party sense, still, when any political action affects industrial and commercial interests, we feel it to be our duty to consider it as regards those interests. The construction of a line of railway across an immense country like that of Siberia is certain to have most important effects on commerce and industry, not only as regards that country, but also as regards neighbouring countries and those which carry on commerce with them.

The first sod of the new railway was cut by the heir to the Russian throne at the end of last month, and the official *Gazette* justly places great emphasis on the importance of the event. That organ mentions, as if it were a matter of national pride, that the line is to be made at the cost of the Imperial Exchequer. When the scheme was first proposed it was suggested that foreign financiers might advance the money, and the Russian directors would remit them their dividends. But men who have money to lend like to have some reasonable expectation that a dividend will be paid, and as the traffic along the proposed line is likely to be very limited for some years the suggestion did not meet with approval. Whether the Russian Minister of Finance has duly considered the extent of the responsibility he has assumed we do not know. Notwithstanding the improvement which has taken place during recent years in the revenues of the Russian Empire, they are not yet in a position to bear the burden lightly. That it will be no light burden if the present intentions are carried out will be evident when it is stated that the Government has resolved to push forward the work with all possible speed, so that the line may be open for traffic in 1895. We are afraid that the engineering difficulties were not fully allowed for when this estimate was formed. We understand that there are no parts of the line which would offer any difficulties under ordinary circumstances. But when it is remembered that the line will traverse an enormous extent of unpeopled country, and that local assistance, either in the way of construction or the supply of materials, will be very limited, we see at once that the expenditure must necessarily be very large. The Russian Government is, however, evidently in earnest in the matter, for they have decided that all the money shown in this year's Budget for works of this class shall be devoted to it, and all other public works and railways are to be left to private enterprise. The energy which is being displayed by the Russians in the construction of the Siberian line will probably give a great impetus to railway construction in China. The Chinese have never hesitated to spend money for purposes of defence, and, in fact, almost all the money they have spent on Western appliances or institutions has been either directly or indirectly devoted to this purpose. We understand that already a railway from Pekin to the Amoor has been surveyed by English engineers, with the object of enabling China to defend the province of Manchuria, and, if necessary, to act in the aggressive should her interests be menaced. On the other hand, the Russian Foreign Minister in some of his despatches has pointed out the immense importance of the Siberian line in the event of a collision either with China or any of the Western Powers, for the line is to be in connection with Vladivostock, which is to be converted into a strong fortress and naval port, but which, in the meantime, is very much at the mercy of any European Power. The construction of the line has been estimated at thirty-five million pounds sterling, and it is quite evident that the interest on this amount, and what is required for maintenance and management, will not be met by revenue, and the deficiency must be met by subsidy. This, however, will not be all loss, for there must result from the construction of the line a very considerable saving in the expenses connected with the government of Siberia. What we ourselves are chiefly interested in is the effects which the line will have on commerce and industry. There can be little doubt that when it is completed it will revolutionise the tea trade with China, and that almost all the tea will come overland. Even as it is, all the best tea comes by caravans, as the sea voyage spoils it, and what is now true of the highest qualities will then be true of all. Some of those who have been doing all they can to promote the construction of the line have described in an enthusiastic manner its brilliant future, and have expressed the opinion that it will result in the creation of a large overland traffic with China and Japan, especially in those goods which are valuable, but not heavy and bulky. They even look forward to depriving England and France of the greater portion of the Eastern carrying trade. That may come in the distant future, but, even if that should be the case, the change will be gradual, and we shall have ample time to suit ourselves to the altered conditions.

The most important industrial result of the construction of the line will be the development of the resources of Siberia, and the impetus which must thereby be given to China. If we can conceive the resources of these countries being fully utilised we may form some idea of what effect such an advance would have on the industrial future of the world. Some who know the resources of China, and the intellectual and physical powers of the Chinese, have expressed the opinion that the future centre of the industrial world will be much nearer Pekin than London. Certainly if America continues to make the progress she has done during recent years, and Russia and China follow in her footsteps, we shall have a very strong argument for an Imperial Federation of all the possessions of Britain, and for a free exchange of all their productions and manufactures. The immediate results of the construction of this line on Siberian prospects will be very considerable. Its vast mineral resources will be developed, and especially its gold mining industry. Eastern and Central Siberia have alone in fifty-four years given to Russia about £120,000,000 worth of gold, while the Ural and Western Siberia have furnished an even greater quantity. With improved machinery and appliances

Digitized by Google

a much greater proportion of gold might have been extracted from the ore, and with greater facilities for transport the number of mines will be very much increased. The other mineral resources are also believed to be very great, but in regard to these little definite information is as yet forthcoming. There are immense tracks in Siberia capable of development for the purposes of agriculture and cattle breeding, which would not only be able to supply food to the increased population which is certain to be the result of the construction of the line, but also to allow a large quantity to be exported to other countries. This may come in good time, for it is believed by many that in a very few years the United States of America will require to import food to supply its increasing population. Thus another remarkable instance of the change of trade and commerce with changed conditions would be afforded. We have briefly indicated some of the possibilities resulting from the construction of the Siberian Railway, and may express a hope that it will require to be used only for the development of trade and commerce, and never for the purposes of war.

THE NAVAL DEFENCE ACT.

The article by Lord Brassey in the *New Review* gives an interesting and reliable summary of the naval force of Great Britain, assuming the completion of the seventy vessels ordered to be built under the Naval Defence Act of 1889. The conclusion at which Lord Brassey arrives is, that the additions to the Navy under this Act will greatly raise the position of Great Britain as a naval Power. It would indeed be rather deplorable if this were not the result of the expenditure of £21,500,000 in addition to the normal outlay upon the Navy. The new force, however, as yet exists largely on paper, for before beginning to deal with the programme of Lord George Hamilton, the dockyards have been busying themselves in completing ships already in progress before the Naval Defence Act was passed. Most of these vessels are now completed, and although none of the new first-class battle-ships will be ready for commission for a long time to come, eighteen second-class cruisers of the "Apollo" type, 3,400 tons, and four second-class cruisers of the "Pallas" type, 2,575 tons, are expected to be passed into the first reserve in 1891-92. Besides the eight first-class battle-ships, each of 14,150 tons, of which the "Royal Sovereign" is the type, including the first-class protected cruisers, each of 7,350 tons, of the type of the "Royal Arthur," there are forty vessels on the "Hamilton programme" which fall to be added to the Navy during the next few years. Lord Brassey quotes from the speech of M. Gerville-Reache, the reporter of the French Budget Committee, by way of summarising the position when those additions are made to the British Navy and when the other contemtemporary accessions are made to foreign navies. M. Gerville-Reache reports that in 1895 the following will be the strength of the navies of France and Great Britain as compared with those of the chief European political combination:—

Relative Strength of European Navies

Class of Vessels.	Ironclads over 10,000 Tons.	Ironclads under 10,000 Tons.	Coast-guard Ships and Plated Gunboats.	Plated Cruisers over 4,000 Tons.	Plated Cruisers between 2,000 and 4,000 Tons.	Despatch Boats and Small Rapid Cruisers.	Counter Torpedo Boats.	Torpedo Boats.	Torpedo Gunboats.	Cruisers of Old Type.	Total Ships Fit for Active Service.
Great Britain	22	32	15	31	51	36	44	156	3	15	402
France	13	20	22	11	5	13	13	187	none	16	299
Triple Alliance ...	17	30	29	13	17	18	39	372	7	24	556

It must be noted that the official expression "fit for active service" is very elastic, and that the numerical statement relating to ships of war is apt to be misleading for several reasons. In the class of ironclads over 10,000 tons, for example, M. Gerville-Reache's number for the British Navy includes three obsolete ships, the "Agincourt," the "Minotaur," and the "Northumberland," while almost all of the thirteen French ironclads are of the most modern construction. The French Navy has been increasing rapidly, and probably the statement is designed partly for Parliamentary purposes, in order to show that further increase is necessary. Especially in torpedo boats, the French are evidently determined to keep the prominent position they have already attained. In 1891 they will construct no fewer than ninety-seven boats of various classes, seventeen sea-going torpedo boats, twenty-four first-class boats, and fifty-six second-class. These additions are, of course, included in the figure given in the table. Germany has at present in construction four first-class ironclads, each of 10,000 tons; two coast defence ironclads, each of 3,600 tons; two cruisers of 5,000 to 5,500 tons; one cruiser of 3,600 tons; one of 1,580 tons; one torpedo sloop of 700 to 800 tons; and two cruisers of 1,800 tons. The speed of the cruisers will be from 18 to 20 knots, and of the ironclads from 16 to 17 knots. Italy is spending this year £3,000,000 in additions to her navy. Altogether six ironclads of 13,090 tons of the "Sicilea" type are now in course of construction. Besides the "Sicilea," "Rè Umberto," and "Sardegna," three other vessels are in hand. Eight cruisers of 2,300 tons, and three deck-protected cruisers, with a displacement of 3,530 tons and a speed of 17 knots, are also being built. There are besides thirteen torpedo sloops and a number of sea-going torpedo boats. Russia has in course of construction three ironclads, each of 10,150 tons, and six of 8,500 tons, and one cruiser of 11,000 tons. While there are many reasons against an unnecessary and excessive increase in naval armaments, it is satisfactory to note that Great Britain relatively to the other naval Powers fully retains the preponderance which has become a tradition.

THE ROYAL SOCIETY CONVERSAZIONE.

The second conversazione of the Royal Society this year was held on the 17th inst., in the Society's rooms at Burlington House.

Professor J. J. Thomson showed a number of experi- on the discharge of electricity through gases without the aid of electrodes, some of which had been shown at the recent meeting of the Physical Society at Cambridge, while others were new. The discharge tube in all these experiments is made to form the secondary of what is essentially an induction coil, and the discharge passes round a closed circuit in the gas. One of the most interesting of these illustrated the fact recently discovered by Professor Thomson, that a magnetic field facilitates a discharge of this kind along the lines of force, while at right angles to them the discharge is retarded.

Professor J. Perry had quite a number of exhibits, of which the following are the most important: (1) A steam engine indicator. This consists of a mirror mounted excentrically upon a disc of thin steel forming one side of a flat cylindrical box into which the steam can be admitted, and was described and illustrated in our issue of the 29th ult. Professor Perry states that the instrument can be relied upon at any speed, however high. (2) "A Simple Means of Destroying Electric Sparking." Sumpner and others have shown that the spark occurring when an inductive circuit is broken could be got rid of by shunting the current just before breaking, through a condenser of sufficient capacity. The capacity required for any ordinary circuits is, however, so great as to make the use of condensers of the ordinary construction quite out of the question, owing to the enormous size which would be necessary. Cromwell Varley, however, pointed out many years ago, that a voltmeter is a condenser, and Professor Perry finds that a few small voltmeters built up of test tubes with electrodes of lead wire in acidulated water form a condenser of sufficient capacity. Four of these were used in the experiment shown. He also exhibited a variable secohm standard and electrical supply meter, and some examples of the twisted strip electrical measuring instruments.

Mr. J. Joly exhibited an instrument, to which he has given the name of "Meldometer," for determining the melting point of minute quantities of substances, by comparison with those of bodies whose melting points are known. The method consists in measuring the thermal expansion of a ribbon of pure platinum, when a minute quantity of a substance, dusted on its surface, and observed through a microscope, is melting. The platinum ribbon is heated by an electric current, and the thermal value in degrees Centigrade of its expansion determined by preliminary observations with bodies of known melting point. The expansion is read by an electro-contact method. The instrument exhibited has a range up to about 1,600° C., and reads to within 2° C.

Professor C. A. Carus-Wilson showed a very ingenious method of experimentally studying the distribution of strain in beams supported at the ends and loaded between the supports. The method consists in submitting a strip of glass to similar stresses and studying the distribution of stress in the glass by means of polarised light.

The Cambridge Scientific Instrument Company exhibited some beautifully constructed instruments, among which was a small cathetometer in which a reading microscope takes the place of the vernier, and the movements take place on geometrical slides. Mr. Crookes showed a series of vacuum tubes illustrating the phosphorescence of various precious stones under molecular bombardment *in vacuo*, and another series illustrating the electrical volatilisation of gold and other metals. Professor Norman Lockyer showed some photographs of a group of sun spots, some solar metallic comparison photographs, and a series of photographs illustrating the orientation of the temples at Karnak and Edfou, and showing that, notwithstanding the elaborate details of the architecture, the principal axes of the temples were kept perfectly clear from end to end.

Professor Roberts-Austen exhibited some beautiful specimens of a new alloy of gold and aluminium, possessing a deeper and more brilliant colour than any other alloy known. Mr. Ludwig Mond exhibited some objects of pure nickel deposited from nickel-carbon oxide, and also some objects plated with nickel by exposure to the same compound. Mr. W. Gardener showed some methods of demonstrating certain important phenomena associated with the absorption and the flow of the water taken up by plants.

Professor S. P. Thompson exhibited an apparatus showing a remarkable optical illusion. On two rotating discs, A and B, are spiral patterns in black and white, which seem to move radially inwards and outwards respectively. Let the observer gaze fixedly for about one minute at the centre of A, and then suddenly transfer his gaze to any object—say the face of a friend—he will see that object apparently enlarging from the middle outwards. After similarly gazing for a minute at B, and then looking at any object, he will see it apparently diminishing. This experiment disproves the theory of M. Javal (Director of the Ophthalmological Laboratory of the Sorbonne), that the complementary subjective illusions of motion are due to involuntarily slipping of the muscles of the eyeball. They cannot slip radially in all directions at once.

Mr. Wimshurst exhibited some electrical influence apparatus, and an electromotor driven by the current obtained from an influence machine. Mr. Francis Galton had a very interesting and important exhibit illustrating his system of identification by means of finger prints. Some of the diagrams show that the essential details, however minute, of the patterns remain unchanged from infancy to old age.

Lantern exhibitions of meteorological photographs were given during the evening by Mr. A. W. Clayden, and of photographs illustrating the district affected by the great eruption of Skapta Tokul in 1783, by Dr. T. Anderson.

The National Telephone Company had connected the Archives Room for the evening with Birmingham and with the Gaiety Theatre at Manchester.

THE FARADAY CENTENARY LECTURE.

On the 17th inst. a lecture was delivered at the Royal Institution by Lord Rayleigh, F.R.S., in commemoration of the centenary of the birth of Michael Faraday, H.R.H. the Prince of Wales being in the chair. The lecturer said that Faraday had been identified with the Royal Institution for a period of 54 years, and found there his opportunity for work and his home. Faraday had been fired by contact with the genius of Davy, and volunteered his services in the laboratory of the Institution. The discovery of Faraday's powers was not the least of Davy's discoveries. Dr. Tyndall, who had possessed opportunities of watching the action of Faraday's mind in dealing with the problems of science, had written an account of him, which had been published in the "Proceedings" of the Institution. The lecturer then described Faraday's great discovery of the induction of electrical currents. The experiment on induced currents was not at that time a simple one, and Faraday did not attain truth without great difficulty. In December, 1824, he attempted to obtain electrical currents by means of a magnet, but it was only on August 29th, 1831, that he obtained the first evidence of induced currents. On September 23rd of that year he wrote to his friend, R. Phillips: "I am busy just now again on electro-magnetism, and think I have got hold of a good thing, but can't say. It may be a weed instead of a fish that, after all my labour, I may at last pull up." Maxwell had invented a differential gearing to imitate the action of induced currents, and the lecturer showed Huygens' gearing, which was an even more exact analogue of the action of such currents. The lecturer showed how Faraday's discovery had been utilised in the construction of alternating current machines for the purposes of electric lighting. The experiments made by Elihu Thomson on the different actions produced by a plate of glass and of copper in electromagnetic screening were then shown. Some of Faraday's most important

Digitized by Google

discoveries were of a similar character. Elihu Thomson's experiment on the repulsion between an electro-magnet and an aluminium ring was also shown. The lecturer said that self-induction was analogous to momentum. As regards mechanical analogues, the lecturer remembered, when a boy, seeing a machine which punched holes in an iron plate 1in. thick, and being told that, even when the machine was disconnected from the engine, the momentum of the fly-wheel would be able to punch several holes, whereas the power of the engine alone, without the fly-wheel, would have been insufficient to punch a single hole. Faraday, he said, felt doubts as to the soundness of the views then held as to the nature of electricity, and was especially desirous not to be misled by the use of words, which often conveyed a meaning beyond what they really were intended to carry. He proved or re-proved the identity of lightning and the electricity of the voltaic cell. He introduced the use of the term "electrode," and had succeeded, as Maxwell said, in banishing the term "electric fluid" to the region of newspaper paragraphs. Faraday also made important experiments on diamagnetism, which had been afterwards developed by Sir W. Thomson. An iron ball would take up a position intermediate between two poles of different polarity, but an eccentric position between two poles of the same polarity. Faraday's experiments had been systematised by Sir W. Thomson. A discovery of immense significance, of which the consequences were not yet fully understood or developed, was that of the rotation of the plane of polarisation of light under electric force. The nature of the vibrations which constitute light was shown by means of a model. The rotation of the plane of polarisation by electric force in a beam of light passing through carbon disulphide was then shown. Sir W. Thomson had shown that this rotation was independent of the direction of the ray, and that there must be something of the nature of rotation in the medium when it was subjected to electric force. The exact nature of this action may not be discovered for some time. In one of his acoustical papers, Faraday stated that he had observed on a flat sea shore that undulations parallel to the course of the wind were caused in the water left behind by the receding tide. The lecturer had been able by close observation to see the same phenomenon, and to recognise the stationary undulations with their ridges parallel to the wind. Faraday must have possessed extremely close powers of observation to recognise this for the first time. Faraday had shown that, after a number of rapid inhalations and exhalations of breath, it was possible to hold the breath for a long time. The knowledge of this fact would have been useful in a recent accident due to the upsetting of a paraffin lamp. If Faraday had undergone a course of mathematical training, he might possibly have been in better *rapport* with the scientific men of his time. Mathematical training and mathematical capacity are entirely different, and Maxwell had said that Faraday's mind was essentially mathematical. The way in which Faraday made use of the idea of lines of force in his magnetic theories showed a mathematical mind, and mathematicians of the future might derive great aid from his valuable and fertile ideas.

Sir William Thomson, in proposing a vote of thanks to Lord Rayleigh for his suggestive lecture, said that the nineteenth century would probably be regarded as the most prolific of all ages by reason of the numerous applications of electricity. Faraday pursued science for the sake of increasing natural knowledge, and left others to apply his discoveries. With reference to Wilde's machine, Faraday said to Wilde: "I gave it you a baby, and you have brought it back a giant." Sir George Stokes seconded the vote of thanks, which was carried unanimously. Sir Frederick Bramwell then read some letters which he had received from persons who had been elected honorary members of the Institution in connection with the Faraday Centenary, and Professor A. Cornu and Professor E. Mascart of Paris, Professor P. Tacchini of Rome, and Professor J. D. Van der Waals of Amsterdam received from the Prince of Wales their diplomas of honour.

A MEMORIAL TO WILLIAM SYMINGTON AT LEADHILLS.

Almost three years ago a movement was started for the purpose of celebrating in some tangible form the centenary of completion of the "Charlotte Dundas" by William Symington, and at that time we directed the attention of our readers to the claims of Symington to recognition as one of those whose work led to the great development which has taken place in steam shipping. We urged his claims, not only on account of the value of his work, but also because during his lifetime he received little encouragement, for it must be remembered that he died broken-hearted and all but penniless. This unfortunately has been the fate of many benefactors of their race, but this much is to be said in favour of the gratitude of human nature, that there generally comes a time when the public conscience is awakened, and an attempt is made to atone for past neglect. We must confess, however, that in the case of Symington that time does not yet seem to have fully come. The movement to which we alluded only resulted in a bust of Symington being placed a few months ago in the Museum of Science and Arts in Edinburgh, and, although this was better than nothing, every one who was interested in the matter felt that something more was wanted.

Another short step has now been taken, which is very appropriate, and which will serve to keep Symington's memory green in his native village of Leadhills; for on Friday of last week there was there unveiled a very appropriate memorial. It takes the form of an obelisk of pure Greek design, about 30ft. in height, and is of polished granite. On the back and front are bronze medallions, the front being a portrait medallion of Symington, taken from a photograph of an old chalk drawing. Underneath is the inscription:—"William Symington, the inventor of steam navigation. Born 1764; died 1831. Erected by public subscription." The medallion at the back represents a model of the "Charlotte Dundas." The memorial may be looked upon as the spontaneous outcome of local feeling regarding the claims of Symington.

THE LATE DAVID BROOKS.

The death of David Brooks, the veteran American electrician, occurred at Philadelphia, on the 30th ult. He was born at Brooksvale, near Cheshire, Conn., on January 26th, 1820. He left College at the age of twenty years, and took a place as instructor in mathematics in the United States Navy. At this time Professor Morse and his associates were engaged in their first experiments with the electric telegraph. Mr. Brooks left the Navy in 1845, to devote himself to the development of this great invention. During that year he put in operation, in connection with James D. Reid, the first telegraph line built in America after Professor Morse's experimental line between Baltimore and Washington. This ran from Lancaster to Harrisburg, Penn., and Mr. Brooks received the first message sent over it. In the following year he built the line across the Alleghanies, connecting Philadelphia and Pittsburgh. From 1854 to 1867 Mr. Brooks was in the service of the old Atlantic and Ohio and the Western Union companies. In the latter year he resigned, and devoted himself to his many inventions and improvements in telegraph and telephone service. In 1873 he was appointed by General Grant as United States Commissioner to the Vienna Exhibition. Mr. Brooks, whose inventions have been of great importance in the development of telegraphy, was a constant contributor to the technical press, and various articles from his pen have appeared in our own columns. We are indebted to our contemporary, the *Electrical World*, for our portrait of Mr. Brooks.

THE LATE PROFESSOR JENKINS.

Our readers will be pained to learn that Professor Philip Jenkins, of Glasgow University, died, after a brief illness, on Saturday afternoon last. A few days previously he caught a slight chill, which brought on an attack of peritonitis, and, although his case was serious from the first, hopes of his recovery were not abandoned until Saturday morning, from which time he rapidly sank. He leaves a widow and three young daughters to mourn his premature death.

Philip Jenkins was born at Dale, in Pembrokeshire, in 1854, and was thus 37 years of age. After serving an apprenticeship as a shipwright in H.M. Dockyard at Pembroke, he entered the Royal School of Naval Architecture in 1873, in which at that time the present Chief Constructor of the Navy was instructor in naval architecture. Under his tuition, and that of the other eminent teachers in that school, he passed with the highest distinction through a complete course of instruction in naval architecture, and thus gave promise of the good work which he afterwards performed. On the completion of his course of study in the school he entered the service of Lloyd's Registry, along with some of his fellow students. At that time the Committee of the Registry were being very severely criticised for their methods and regulations regarding the building of ships, and they felt that they ought to strengthen their position by retaining the services of men who had good practical experience, and who were also thoroughly well versed in the theory of their business. Jenkins and his companions soon exercised considerable influence on the work of the Registry, and the criticisms which had been made regarding it were for the most part met. Their influence, however, was not confined to their official positions, but was communicated to the profession through papers read before the Institution of Naval Architects, and these papers were recognised as proceeding from men whose opinions were of great weight. The papers were chiefly on the strains to which ships were subjected, and their strength considered as structures. This department of the subject remained the one to which Jenkins continued to direct special attention, and last year he read before the Institution of Naval Architects an important paper, "On the Strength of Ships, with Special Reference to the Distribution of Shearing Stress over a Transverse Section," and which was very highly spoken of in the discussion which followed. For more than a year he has been a member of a special Committee on Bulkheads, and we understand that the report on the subject is quite completed and will shortly be published. It is certain to be very carefully studied at the present time, when the subject of the speed and safety of steamships is receiving so much attention.

On the appointment of Professor Elgar, of Glasgow University, to the position of Director of Dockyards, Mr. Jenkins was asked to act as his *locum tenens*, and this he did with so much ability that shortly afterwards he was appointed to the Chair of Naval Architecture, which he has continued to fill with the highest efficiency. At the meeting of the Institution of Naval Architects, in Glasgow, in July, 1888, he read a paper giving a very complete account of the course in naval architecture at Glasgow University, which showed the breadth and depth of his knowledge, and the thorough manner in which he had arranged the work of his department. His system may be considered a model for all similar departments in universities or technical institutions. His energies were not by any means confined to his college duties. In addition to a fair share of consulting work, he had taken a very active part in the formation of the new Shipping Registry in Glasgow, and held the appointment of scientific adviser to it. His quiet and pleasant manner endeared him to his students, his colleagues, and his friends. In short, his death has left a blank not only socially, but also in the scientific world, to which he was so well qualified to impart information regarding his own department of investigation and practice.

Letters to the Editor.

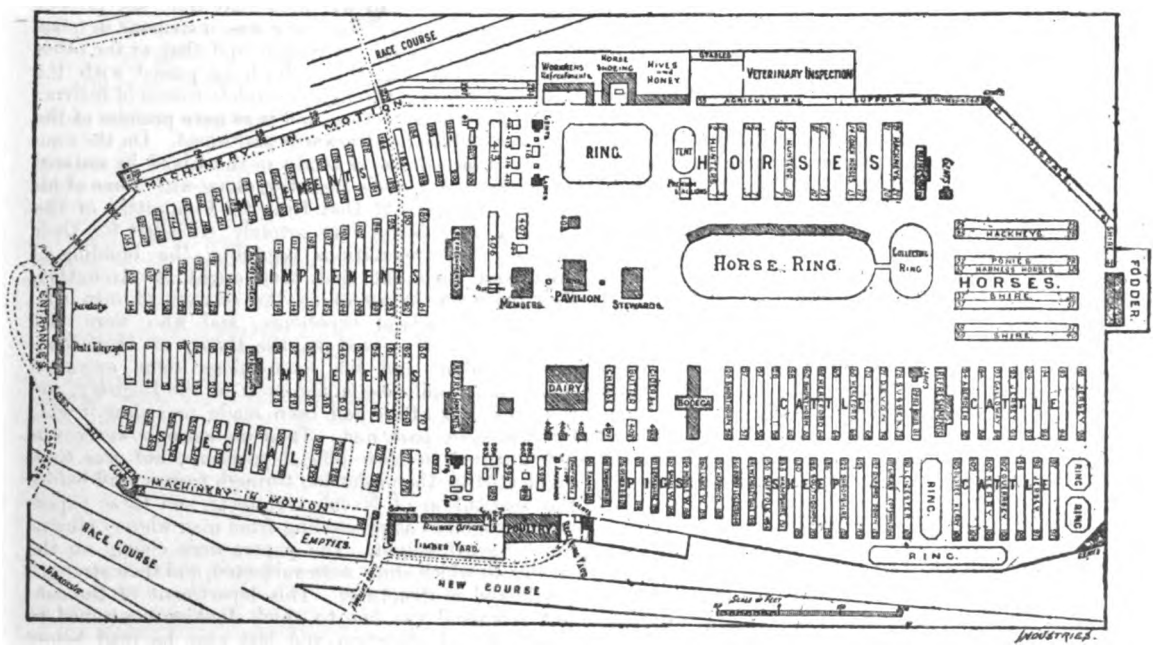
CHARLES' BRUSH HOLDER.

To the Editor of "Industries."

Sir,—With regard to "Charles' Brush Holder," described in your issue of the 5th inst., I may say that I designed and have used for the last two years a brush holder similar to the one described, and I can fully confirm your opinion as to its simplicity and efficiency. To my brush holder I add an improvement, not obtained in Mr. Charles' holder, in the form of an adjustment screw for regulating the tension of the spring. I have had a dynamo running through the past winter, and the brushes on the same have never required attention, which I attribute to the use of this brush holder.

Yours, &c.,
R. Forster,
Electrican to Messrs. J. Sunderland & Co.

Halifax, 12th June, 1891.



THE STEAMSHIP OF THE FUTURE.

To the Editor of "Industries."

Sir,—The two articles which appeared in your last issue, namely, "The Steamship of the Future" and "Safety in Ocean Travelling," direct the attention of your readers to matters which are rapidly assuming increasing practical importance. In these, as in all other matters, it is safer to proceed by a gradual evolution than by a sudden revolution. A steamship to cross the

Digitized by Google

THE ROYAL AGRICULTURAL SHOW.

PLAN OF SHOW YARD.

Atlantic in three days is no doubt within the possibilities of the not very distant future, but in the meantime shipowners and shipbuilders should show that a five days' steamer can be built with ease. Your estimate of 30,000 h.p. is, in my opinion, on the safe side. I think that 25,000 h.p. would be found sufficient if all other conditions were proper, but, as you point out, all these figures must be largely matters of guess in the absence of practical experience. Experiments with models are no doubt useful, but with these higher speeds the elements of uncertainty are very much increased, and the only sure way is to advance slowly in the size and speed of the actual boats.

With regard to bulkheads, the importance of which you point out, we are waiting, with a certain amount of impatience, the report of the Special Committee which has been sitting for some time on the subject, and which is said to have been completed for a considerable period. It may be assumed that shipowners and shipbuilders have practically decided, after a good deal of hesitation, to have all their largest and swiftest ships with twin screws, a decision which is justified, not only on grounds of safety, but also of efficiency.

While advising caution in the construction of these large and expensive ships, it would, however, be well if shipowners, shipbuilders, and marine engineers allowed their imagination a little play occasionally as to the possibilities of the future, for it must be remembered that imagination has a most important function in scientific and industrial development. The man who boasts that he is a "practical man," and does not indulge in experiments, forgets that if all were like him no progress would be made. He is like those very prudent people who are so very much afraid of making a mistake that they seldom or ever do anything beyond the ordinary routine of everyday life. The whole subject of prime movers *may*, for instance, be revolutionised by a proper use of the imagination, for, instead of increasing the size of our engines, we may find some more direct method of utilising the energy inherent in the fuel than through the rather clumsy means of a steam engine. In electric motors, any one with a little imagination must at once be struck with the roundabout methods adopted, and come to the conclusion that, if we knew a little more about electricity, we might at once dispense with a great deal of heavy and expensive machinery.

The steamship of the future may have a much simpler and much more efficient prime mover than anything at present imagined; it may be built of material at once lighter and stronger than any at present within the reach of engineers and shipbuilders, and consequently it may become possible to greatly increase the speed without adding to the danger. The improvements in navigation to which you have alluded make a difference in speed of comparatively little moment.

Yours, &c.,

Glasgow, 18th June, 1891. M.I.N.A.

AN ATLANTIC LINER ON FIRE.

ON the night of the 9th inst a fire broke out in the hold of the Inman and International steamship "City of Richmond," during the voyage from New York to Liverpool. The vessel left New York on the 3rd inst., and when the fire was discovered it was in lat. 25 N., long. 39 W. There were on board 105 cabin, 71 second cabin, and 119 steerage passengers, and a crew of 146, the cargo including 2,000 bales of cotton. A strong hurricane, with heavy cross seas, was experienced on the 7th inst., and the heavy seas continued up to the 9th inst. At midnight on the 9th inst. the alarm of fire was given, and the passengers were quickly on deck. It was soon discovered, on opening the hatchway near the cabin, where the smoke was first seen, that the cotton in the hold was on fire. Captain Redford and the officers made every effort to extinguish the fire by forcing water and steam into the hold, and all apertures were closed in order to prevent the access of air. The fire was at last checked by these means, but the cotton still continued to smoulder. Preparations were made for victualling the boats, but it would have been very difficult to put them off, in consequence of the heavy sea then running. At 8 a.m. on the 10th inst. a sail was sighted, and, after signals had been made, a vessel drew near, which proved to be the "Counsellor," of the Harrison Line, bound for Liverpool. This vessel agreed to remain alongside the "City of Richmond." During the evening of the 10th inst. an attempt was made to examine the hold, and four bales of smouldering cotton had been removed when it became necessary to shut down the hatches. On the night of the 10th inst. the Cunard steamer "Servia," seeing the signals of distress, drew near, and on the morning of the 11th inst. the "City of Richmond" and the "Servia" proceeded together. The Inman Line steamer "City of Paris" came up with the two vessels on the afternoon of the 12th inst., and a consultation took place between the captains of the three vessels. It was ultimately agreed that the "Servia" should accompany the "City of Richmond" to Queenstown, whilst the "City of Paris" should proceed on her voyage to New York. On the 13th, water and steam continued to be poured into the hold, but the vessel appeared to be getting hotter. On the morning of the 14th the vessel arrived at Queenstown, and proceeded to Liverpool, crossing the Mersey bar on the morning tide of the 15th inst.

On the afternoon of the 17th inst. the vessel was taken into Hornby Dock, and the part of the hold in which the fire originally broke out having been open, dense clouds of smoke and flames issued from it. The heat of the vessel was very great, and a powerful stench arose from the burning meat and cotton. A large quantity of water was again poured into the hold, but little effect seemed to be produced.

THE NORWOOD JUNCTION RAILWAY ACCIDENT.

MAJOR-GENERAL HUTCHINSON, of the Board of Trade, has issued his report on the above accident, which, it will be remembered, was caused through the collapse of a bridge. The report states that "the cast iron girder which failed, causing the floor of the bridge to give way, and the wheels of the engine and tender, and then all the succeeding vehicles in the train, to leave the rails, had been in its place on the west side of the up main line for about 31 years, and during the whole of that time had had concealed in the interior of the web and in the outer part of the lower flange a very serious flaw, abstracting at least one-fourth from the strength of the girder." This flaw was invisible when the girder was in position, and even when the girder was cast, owing to the practice of using sheet iron in the foundry operations at special parts of the castings, such as gussets, where the flaw could not be perceived. The report further states that, apart from the flaw, "this girder did not possess a sufficient theoretical margin of safety for the passage of the engines now in use on the line—its calculated breaking-weight at the centre, supposing the bottom flange to be perfect, not exceeding 71 tons, whereas, for the engine drawing the express train, this breaking-weight should have been at least 83 tons, and more for other engines running on the same line."

The attention of the London, Brighton, and South Coast Railway Company had been drawn by the Board of Trade to this deficiency of strength after a previous accident on this bridge in 1876, when two similar girders at a different part of the same bridge were broken owing to an engine becoming derailed, and they were then recommended to substitute stronger girders, a recommendation which had, unfortunately, been unheeded. The Brighton Company, the report goes on to show, "is therefore deserving of much blame for having omitted to substitute stronger girders for the existing ones, after attention had been thus specially directed to the weakness of the latter." The comparatively slight personal injury and damage to rolling stock caused by the accident, the report states, is owing to the strength of the vehicles and the prompt action of the engine-driver Hargreaves in applying the Westinghouse brake. The General commends the promptitude of the signalman Sawyers, who was on duty in the Norwood North cabin, in at once blocking the "up local" and "down main" lines. The engineer to the company states that there are only five such cast-iron bridges still in existence on the main line between London and Brighton, and the Board recommends the immediate reconstruction of these with wrought-iron girders.

THE ROYAL AGRICULTURAL SHOW.

THE fifty-second annual Show of the Royal Agricultural Society will be held at Doncaster from to-morrow, the 20th inst., to Friday, the 26th inst., inclusive. On the first day the implement department only will be open to inspection, and the show of live stock will be open on Monday, the 22nd. On Tuesday, the 23rd, at 12.30, a general meeting of the members of the Society will be held. The usual competitions will be held during the week, such as horse-shoeing, butter making, &c., while lectures and demonstrations in dairy work and bee-keeping will take place at intervals. We give above a plan of the show yard, which is reproduced from the Society's official catalogue, and which may be of use to our readers.

Reviews.

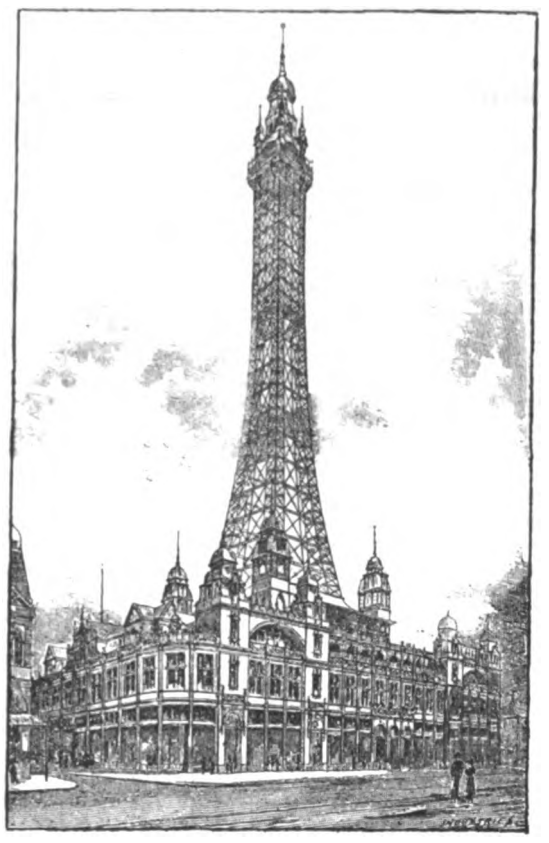
THE DESIGN OF STRUCTURES. By S. Anglin, C.E. London: CHARLES GRIFFIN & Co. 1891.

It is very appropriate that the publishers of Professor Rankine's series of well-known manuals, which laid the foundation of engineering science in this country, should continue to place before the public the developments which are in great part due to Rankine's work. Some time ago we had occasion to notice the excellent treatise of Professor Fidler on bridge construction, and now we have before us a more general treatise on the design of structures, which is of very high quality. There may not be very much that is original in it, but what ordinary students and engineers want is not so much originality as a clear and concise statement of the present state of knowledge in different departments. Mr. Anglin's object has been to supply students of engineering and architecture with a concise text-book on structures, requiring on the part of the reader a knowledge of elementary mathematics only, and he has performed his work in a most admirable manner. He has tried to treat the different branches of the subject from a practical as well as from a theoretical standpoint, and with this object he has introduced, and carefully worked out, a large number of practical examples such as occur in the everyday experience of engineers. These will be found most useful, not only for their practical applications, but also because in some cases they are solved both analytically and graphically, the one method being used to check the other.

Throughout the book Mr. Anglin has made a very judicious use of graphic statics in its application to the determination of stresses on framed structures. We have often complained of the manner in which some writers and teachers take up this branch of the subject; they make it too much of a hobby, and elevate it into the position of a special science, almost as intricate as that of which it is only meant to be the tool. The first three chapters of the book are preliminary, and deal chiefly with the strength and elasticity of the materials used in construction, and will be found to contain a

Digitized by Google

most useful synopsis of the subject. The fourth chapter considers briefly the mechanical laws relating to stresses on structures and the graphic methods of representing them. The action of loads of different kinds on beams placed in different conditions is next very fully considered, and in a very clear and concise manner, and illustrated by well-chosen examples. Columns and struts, girders of different kinds, framework, arches, roofs, and bridges are all taken up very fully, and in a manner which will be most useful both to students and engineers. In these departments, and in order that the work may be useful as a book of reference to those engaged in the profession generally, several chapters are devoted to the practical side of the subject, especially to such matters as strength of joints, punching, drilling, riveting, and other processes connected with the manufacture of bridges. On these subjects Mr. Anglin writes with the experience of many years in the bridge yard, and the information which he gives will be found to be of great value to the practical bridge builder. Mr. Anglin's book comes very near to our ideal of what such a text-book should be, and we have very much pleasure in recommending it to the attention of our readers who may be interested in the subject.



Wedding's Basic Bessemer Process. Translated from the German by William B. Phillips, Ph.D., &c., and Ernst Prochaska, Metallurgical Engineer. New York: Scientific Publishing Company. 1891.

It is natural that Germany, having derived more advantage from the basic process than any other country, should contribute to technical literature the most complete work upon its methods. This we have in the book before us, which is an English translation made for the express purpose of acquainting American metallurgists with the details of an invention that has not met with a favourable reception at their hands; the Pottstown Iron Company, of Pennsylvania, being as yet the only firm that has made any serious attempt to manufacture basic steel in the United States. Throughout the book, following the German original, the process is called by the name of "Thomas" alone, and, except for a reference to Percy C. Gilchrist on page 30 this gentleman might have had no connection with the discovery, for his name is even absent from the index, an omission of a somewhat remarkable character, seeing that the opening chapter is chiefly historical. The early attempts at dephosphorising are described, and it is shown how the important discovery was arrived at that, of all the methods and materials which can be employed for the manufacture of a basic converter lining, the mixture of dolomite and anhydrous tar now usually employed is the most practical. The construction and lining of the converter are, in common with other mechanical points, very fully illustrated. Owing to the large amount of slag resulting in the basic practice much larger converters have to be used for the same charge than in the acid process. The ratio, the author tells us, is about 6·5 to 10—that is, a converter able to take 10 tons of iron in the acid process could only take 6·5 when used for the basic process. In regard to the materials, it is considered that the best pig iron for use in the basic process is that made at Ilsede, Germany. It contains about 3 per cent. of phosphorus, over 2 per cent. of manganese, 0·5 per cent. of silicon, and less than 0·1 per cent. of sulphur. The absence of any large amount of sulphur is important, for, to use the author's concluding words, "It is still an open question how to desulphurise, practically and economically, a phosphoritic pig iron in the basic Bessemer converter." The use of the term "recarbonisers" to designate spiegeleisen and similar carbon-containing compounds, is hardly correct. A material is "carbonised" when, as for example, a piece of wood is charred, the carbon is present in it from the commencement of the operation, but it is "carburised" when the carbon is added to it, as in the manufacture of steel. "Recarburisers" is therefore the better expression to designate such materials as spiegeleisen and ferro-silicon. The details of practice and the chemical and physical reactions of the process are very fully discussed, and illustrations showing the best arrangement of a basic Bessemer works are also given. Not the least important is the section that refers to the utilisation of the slag, which is largely used for agricultural purposes. It is an interesting fact that, since vanadium behaves exactly like phosphorus, the whole amount present in any ore is found in the basic converter slag, and this element can be profitably extracted from it in the form of sodium vanadate used as a pigment. That excellent steel can be produced by the basic Bessemer process is now a well-established fact. Nevertheless, the necessity for the use of lime in the slagging operation seems to be opposed to the manufacture of an ingot iron that shall not have its welding properties interfered with. To the absence of this violent action is probably due the improvement in the quality of the steel obtained from the basic open-hearth furnace, a branch of the subject upon which Mr. Ernst Prochaska has added a supplementary chapter from his pen giving an account of the progress made during the last six years. It is found that the best results in the basic open-hearth furnace are obtained on a magnesite bottom, a material which remains intact when exposed to the highest heat of a regenerative gas furnace, whilst dolomite exposed to the same treatment fluxes.

In conclusion, we may add that although this important work appeals with special interest to the steel maker, the copper smelter will find in it much that may be of value in his future practice as foreshadowed by Mr. Gilchrist in his paper on "The Basic Process as Applied to Copper Smelting," read before the London Section of the Society of Chemical Industry, an abstract of which appeared in *Industries* of 9th January last.

THE BLACKPOOL EIFFEL TOWER.

The accompanying illustration represents the Eiffel Tower which it is proposed to erect at Blackpool, the well-known Lancashire watering-place, the designs for which have been made by Messrs. Maxwell & Tuke, of Manchester. The situation chosen for the tower is between the North and South Piers. The tower will be between 400ft. and 500ft. high; the base will be used as a circus, the first floor will contain a menagerie and aquarium, and the second floor a concert room and floral hall. The tower proper will be 100ft. square at the base,

and 30ft. square at the foot of the cupola. The first gallery, 70ft. above the ground, will be 80ft. square, and the second gallery, 300ft. above the ground, will be 30ft. square. Hydraulic lifts, capable of accommodating 20,000 visitors a day, will run up to the second gallery, and thence broad staircases will lead to the six upper galleries and the lantern and cupola. The tower will be constructed of wrought iron and steel, and will be lighted throughout with electricity. We are indebted to the *Graphic* for our illustration of the tower.

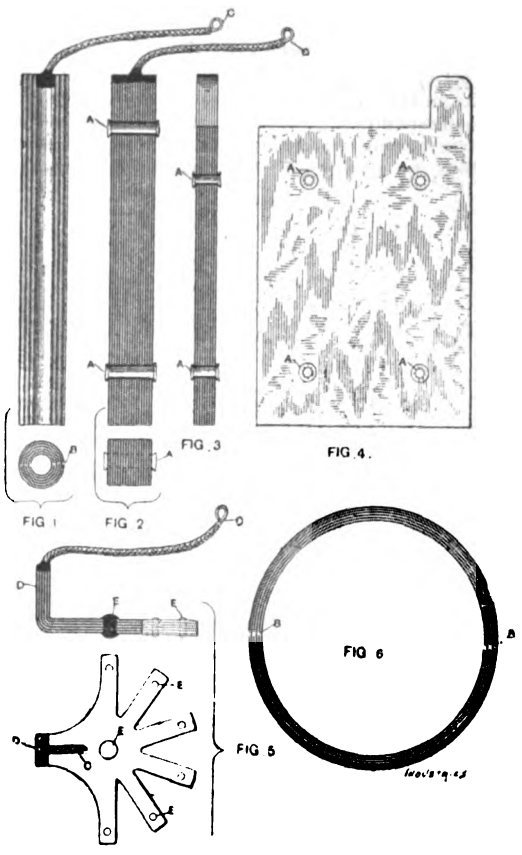
THE INSTITUTION OF CIVIL ENGINEERS.

The following is a detailed list of the awards made for communications submitted during the past session:—

For Papers Read and Discussed at the Ordinary Meetings.

1. Telford Medals and Telford Premiums to Llewellyn Birchall Atkinson, A.K.C., and Claude William Atkinson, A.K.C., Assoc.MM.Inst.C.E., for their joint paper on "Electric Mining Machinery." 2. A Telford Medal and a Telford Premium to Rookes Evelyn Bell Crompton, M.Inst.C.E., for his paper on "The Cost of the Generation and Distribution of Electrical Energy." 3. A Telford Premium to Frederick Ewart Robertson, M.Inst.C.E., for his account of "The Lansdowne Bridge over the Indus at Sukkur." 4. A Telford Premium to Edward Walter Stoney, M.E., M.Inst.C.E., for his description of "The New Chittravati Bridge, Madras Railway." 5. Telford Premiums to Professor John Milne, F.R.S., and John McDonald, for their joint paper "On Vibratory Movements of Locomotives, and on Timing Trains and Testing Railway Tracks." 6. A Telford Premium to William Langdon for his paper on "Railway Train Lighting." 7. A Telford Premium to William Thomas Henney Carrington, M.Inst.C.E., for his paper on "The Reception and Storage of Refined Petroleum in Bulk."

For Papers Printed in the Proceedings without being Discussed.



1. A Telford Premium to Bryan Donkin, Jun., M.Inst.C.E., for his paper on "Thermometers in and about Steam-Cylinder Walls; with some Experiments on the Temperature of the Metal under Different Conditions." 2. A Telford Premium to John James Webster, M.Inst.C.E., for his paper on "Fire-proof Construction." 3. A Telford Premium to Charles Preller Sheibner, Ph.D., Assoc.M.Inst.C.E., for his account of the "Carrara Marble District Railway."

For Papers Read at the Supplemental Meetings of Students.

1. A Miller Prize to Edmund Lewin Hill, Stud. Inst.C.E., for his paper on "The Counterbalancing of Locomotive Engines." 2. A Miller Prize to John Henry Barker, Stud. Inst.C.E., for his paper on "The Design of Locomotive Cylinders." 3. A Miller Prize to William Archer Porter Tait, B.Sc., Stud. Inst.C.E., for his account of "The Lanarkshire and Ayrshire Railways." 4. A Miller Prize to Bertram Chatterton, Stud. Inst.C.E., for his paper on "Disintegrators." 5. A Miller Prize to John Walter Brown, Stud. Inst.C.E., for his account of the "Malta Dockyard Caisson No. 4." 6. A Miller Prize to Auriol Sealy-Allin, Stud. Inst.C.E., for his description of "A New Type of Water-Motor." 7. A Miller Prize to William Herbert Wheeler, B.A., Stud. Inst.C.E., for his paper on "The Cleaning and Deepening of Rivers and Canals by means of the Transporting-Power of Water."

IMPROVED BATTERY ZINCS.

Messrs. David Moseley & Sons, Chapel Field Works, Ardwick, Manchester, have brought out an improved form of battery zinc, which we illustrate herewith. The object of the invention is to get over the difficulties due to local action. Each zinc is made up of laminæ of thin sheet, each sheet being amalgamated separately, so that the zinc is practically amalgamated throughout. Fig. 1 shows a Leclanché cell zinc. It is built up of concentric tubes made of amalgamated sheet zinc. Fig. 2 is a rectangular rod, the strips composing it being held

together by ebonite tubes, with the ends expanded by a hot tool, so as to hold on the principle of boiler tubes. Figs. 3 and 4 show a composite plate, and Figs. 5 and 6 a star and a cylinder respectively. It is claimed that these zincs are free from local action, because the metal is purer and more homogeneous, as it is rolled in thin sheets and thoroughly amalgamated. Also that they are as cheap as ordinary zincs, do not get covered with crystals, and never require cleaning. With the view of testing these claims we are trying a "Moseley" and an ordinary zinc in a newly set up pair of Leclanché cells.

SETTING UP STANDARD CELLS.

By S. Skinner, M.A.

The Board of Trade has issued a preliminary memorandum on the preparation of the Clark's cell, which is a standard of electromotive force or electric pressure. It affords the most convenient method of testing the graduations of volt and ampere meters, and it is probable will come into general use for testing household electric meters. The memorandum contains instructions for preparing the cells, and, although these are very full, experience tells us that it will not be out of place to explain and expand some of the details. The principal sources of error in a Clark's cell are—(1) The paste may be acid; (2) it may not be saturated with zinc sulphate; (3) the solution may be supersaturated; and (4) the mercury may be impure. (1) and (2) cause the e.m.f. to be too high, and (3) and (4) cause it to be too low. We propose to indicate here the precautions necessary to guard against these faults.

To prepare the zinc sulphate solution, the instruction is to dissolve 2 parts by weight of pure recrystallised zinc sulphate in 1 part by weight of water, with the aid of a gentle heat. To this a small quantity of zinc carbonate is added, in order to neutralise any free acid.

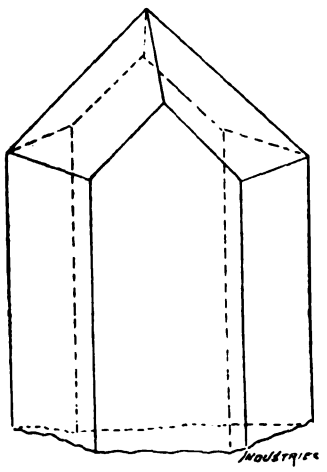

Fig. 1.

This milky solution is to be filtered, whilst warm, into a stock bottle, where part of the zinc sulphate, on cooling, separates in crystals. The solution, which is milky from the presence of an excess of zinc carbonate, becomes quite clear after passing the filter, but on cooling there is the separation, in addition to the zinc sulphate in trans-

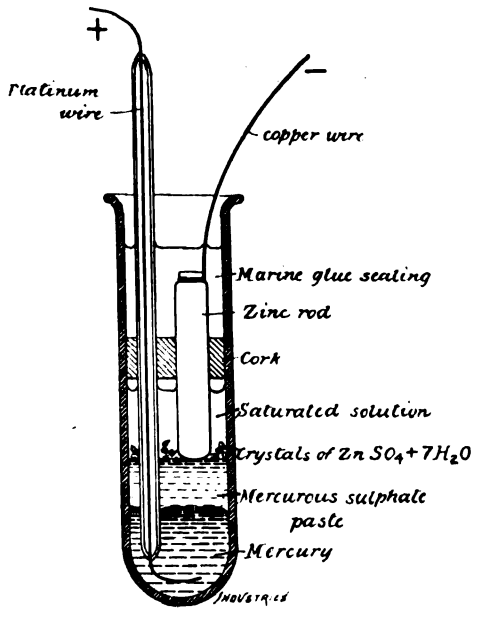

Fig. 2.

parent crystals, of a small quantity of very minute white opaque crystals. The presence of these crystals does not matter; they are a basic sulphate of zinc due to the interaction of the carbonate on the sulphate. Very frequently no crystals of any kind appear on cooling, especially if the bottle be very clean and has been kept still. This is due to the phenomenon of supersaturation. To bring the crystals down, the best method is to drop in one or two; the smallest quantity is sufficient from the purchased sample. The solution, when prepared, should just turn a blue bitmus paper to a purple colour.

There are several kinds of crystallised zinc sulphate, and it is essential to use the rhombic crystals $ZnSO_4 + 7H_2O$. These separate from solutions below 30° C., and have the shape shown in Fig. 1. If the solution has crystallised whilst still warm, say, at 30°, it is highly probable that the salt separated is $ZnSO_4 + 6H_2O$ (monoclinic crystals), and should this be used the e.m.f. will be too low. We cannot lay too much stress on the use of the right crystals; it is one of the most important features of the cell.

To prepare the paste mercurous sulphate is washed with cold distilled water *until free from acid.* The water is then drained off so as to leave the powder as dry as possible. If the sample of mercurous sulphate contains mercuric, it will be indicated at this stage by the powder becoming yellow. To the drained powder zinc sulphate solution is added to bring it to the consistence of cream, then a little mercury and some crystals from the stock-bottle to saturate the water left adhering to the paste from the washing. This is warmed and well ground together, and at this stage the yellow colour should disappear, since the mercury added will change any mercuric salt back to mercurous salt. When this is cold still more crystals should be added, so that we may be absolutely sure that there are present actual crystals visible to the eye besides the mercury, mercurous sulphate, and saturated zinc sulphate solution.

A finished cell is represented in Fig. 2, drawn three-quarters size from an actual cell. The e.m.f. of the cell is 1·435 Rayleigh volts at 15°, diminishing by ·001 volt for every degree above 15°, or increasing by the same amount for each degree below that temperature. The cell should be mounted with a thermometer in close contact to indicate its temperature.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

(*From our New York Correspondent.*)

(*Concluded from page* 571.)

At the opening of the meeting on the 21st ult. the Chair was authorised to appoint five delegates to the Frankfort Electrical Congress.

The first paper read was by Professor Geo. S. Moler, on "An Alternate Current Potentiometer," designed for determining what values of the potentials of alternating currents will produce given effects, and to be used principally for calibrating alternating current voltmeters. The instrument, briefly described, is as follows:—An incandescent lamp is so arranged and connected that it can be switched back and forth from the terminals of an alternating current line to those of a direct current line, which can be altered in voltage till the lamp glows with the same intensity when fed by either line. Then, while switched into the direct current line, the voltage of that line is measured by a direct current standard voltmeter or potential instrument, and the voltage so read is equivalent to that of the alternating current, which produces the same effect in the lamp. The switch is so constructed that it snaps back and forth, making the change of connection so quickly that the slightest change of intensity of the light can be easily detected. The lamp has a blackened hood with an opening in one side, through which it is viewed while the sliding resistance is being adjusted. This enables the observer to make a much closer setting than otherwise. A very close setting may also be made by observing the slight reflection of the light from the blackened surface of the hood. The sensitiveness of the instrument increases with the brightness of the lamp up to a certain point. It is best to use a lamp about the voltage which is to be measured. Mr. Weston thought that the plan was a good one, and should give accurate results. Professor George Forbes suggested that the sensibility of the instrument could be greatly increased by using two lamps in a properly constructed photometer, with a switch arranged to connect either of them with an alternating or continuous current.

A paper was then read by Mr. Frank J. Sprague, entitled "Considerations which should Govern the Selection of a Rapid Transit System." It referred especially to the requirements of New York City. Professor Forbes, in the discussion which followed, spoke of the success of the South London Railway as proving the possibilities of electric traction on a large scale. That system was now working perfectly, some of the earlier difficulties having been entirely overcome.

Mr. George W. Walker afterwards read a paper on "Electric Meters," which, after briefly describing various meters in use, described one of his own invention, which was in operation on the platform. He thought inventors had erred in striving to produce a meter registering in a similar manner to a gas meter. The principle of the meter described was that of photographing a record of the movements of an ammeter needle, which eliminated friction. The roll of sensitised paper was moved by clockwork set in operation by the turning on of a single lamp. A 1 c.p. lamp was sufficient to make the record. After a certain period of time, say, a month, the roll is taken from the meter, and the record developed, and measured with a planimeter. The discussion indicated that there was a practical reason for preferring a dial recorder, as it was more satisfactory to the customer.

Mr. Milton E. Thompson then read a paper on "A Study of an Open Coil Arc Dynamo," which was intended to determine accurately, by taking instantaneously throughout the revolution, the character of the external and internal currents and electromotive forces.

A paper was then read by Dr. Wm. H. Wahl, on "The Future of the Aluminium Problem from the Chemical Standpoint." He stated that there were other methods besides that of fusion for obtaining alumina in the liquid state. He believed there were solvents for alumina, and, if the fluid condition was as important as was believed in inducing chemical reactions, there was a possibility of establishing conditions favourable to the reduction of alumina by carbon at temperatures, perhaps, far below the fusion point of alumina. The fluorides of the alkalies, and the alkaline earths, we had reason to believe, dissolve alumina freely, and there were other compounds into which alumina enters that may be dissolved in the proper menstrua. Summarised, the case stands thus: The processes in which electricity is applied, either for the direct reduction of aluminium by electrolysis, or as the agency for producing the heat required to effect its reduction by chemical reactions, have outstripped the metallurgical methods in the race for supremacy, and have taken a decided lead. Within the past two years the metallurgical processes, as represented by the improved methods of Castner, Netto, Grabau, and others of less renown, have been forced to abandon the field to the electrical methods of Hall, Minet, Cowles, and Heroult.

At the close of the meeting the members of the Institute were given a reception at the Electric Club, at which a very interesting collection of historical matter was displayed, which had been gathered for the occasion.

PENN'S IMPROVEMENTS IN PETROLEUM LIGHTING.

The Penn's Lamp and Lighting Company, Limited, have recently introduced to the public some improvements in petroleum lighting which are worthy of notice. The first is the gravitation system, which enables a building or town to be lighted from a central reservoir placed in an elevated position, by means of pipes, in a manner similar to that employed for gas illumination. The delay in satisfactorily accomplishing this end has been hitherto due to the difficulty of regulating the supply of petroleum to the lamps. This difficulty has now been overcome by the use of a float and regulating valve (shown in Figs. 1 and 2) in connection with each lamp. Referring to the illustration, A is the oil cylinder in which the wick is suspended, and contains a closed float E connected by a rod F to a valve G. The special feature of the valve G is that it is of conical form, but recessed between its largest and smallest diameters, and that the oil is directed against the recess, thus rendering the valve extremely sensitive. The oil is admitted from the inlet pipe I, which is in communication with the reservoir while the valve is depressed, passing upwards into the oil cylinder. The increasing level of the oil raises the float, and with it the valve, and thus the supply is arrested. As the oil in the cylinder is consumed the valve descends and permits a fresh supply to enter. Thus the oil in the cylinder is practically kept at a uniform level, with the result that the lamp burns steadily. We recently had an opportunity of inspecting various forms of these lamps supplied from one reservoir at the company's offices, Abchurch Yard, Cannon Street, London, E.C. We understand that an installation has been applied at Cuxton Station, on the South-Eastern Railway, with the supply tank fixed at a level of 23ft. above the level of the platform. From the tank the service pipes descend below the rails, rising to each lamp column or suspended light, wall bracket, and two-light pendant. The light given is very satisfactory. By means of a small flash-light the lamps can be lighted and extinguished without trimming the wick, except at long intervals, and the wick can be raised and lowered from a distance by the lever N and wires R. The method of doing this is as follows:—To the outer extremity of the spindle K is fixed a circular disc having holes in its periphery, and attached thereto is the lever N. At starting the wick is adjusted to the required height, the lever being in the meantime free; but it is then fixed to the disc by the set screw Q passing into one of the holes therein. It follows that the wick can be lowered or raised the exact distances necessary by pulling the wires

PENN'S IMPROVEMENTS IN PETROLEUM LAMPS.

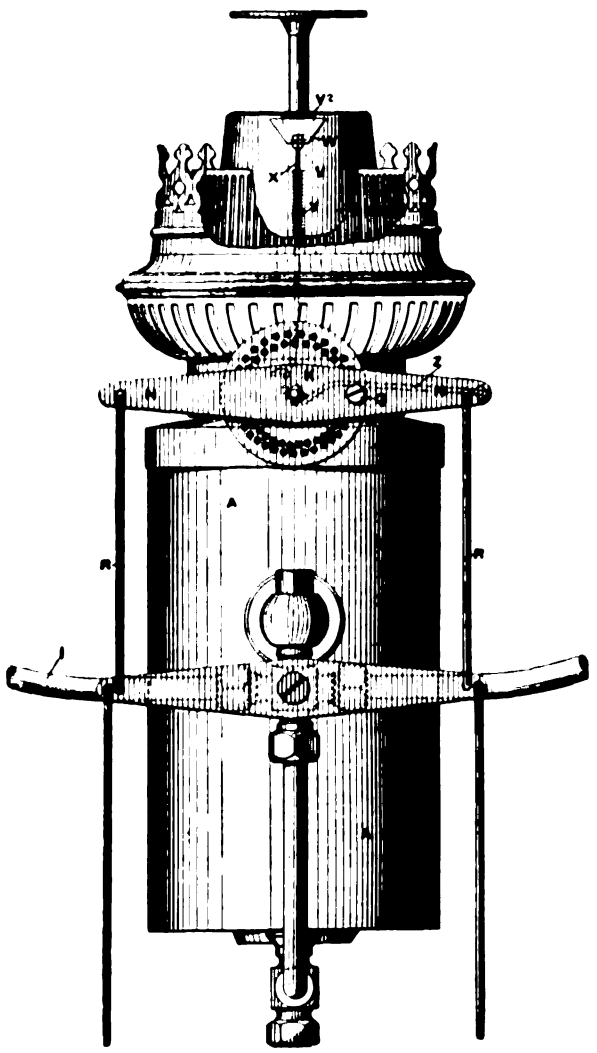

FIG. 1.

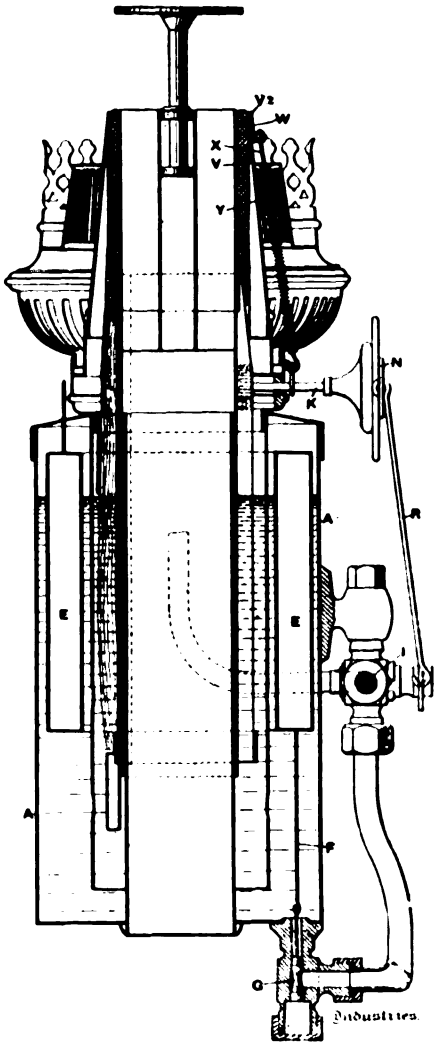

FIG. 2.

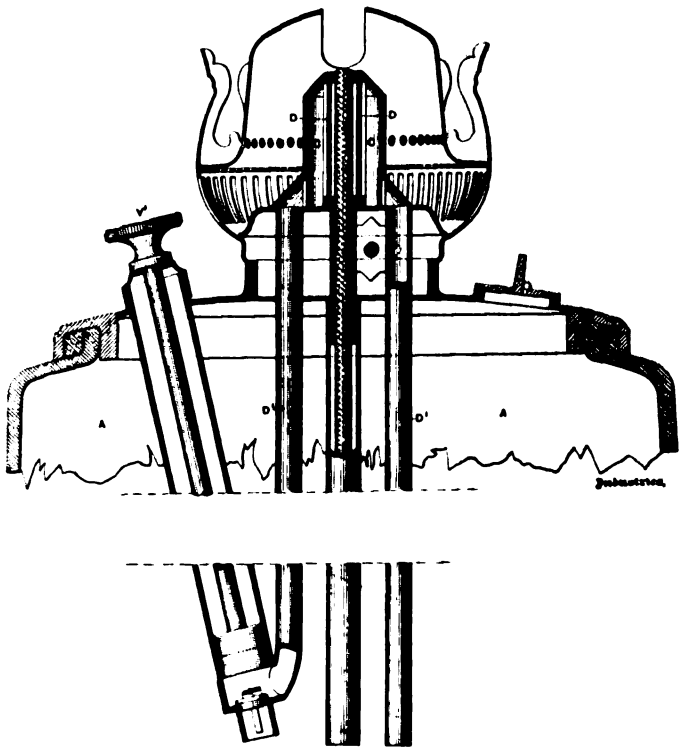

FIG. 3.

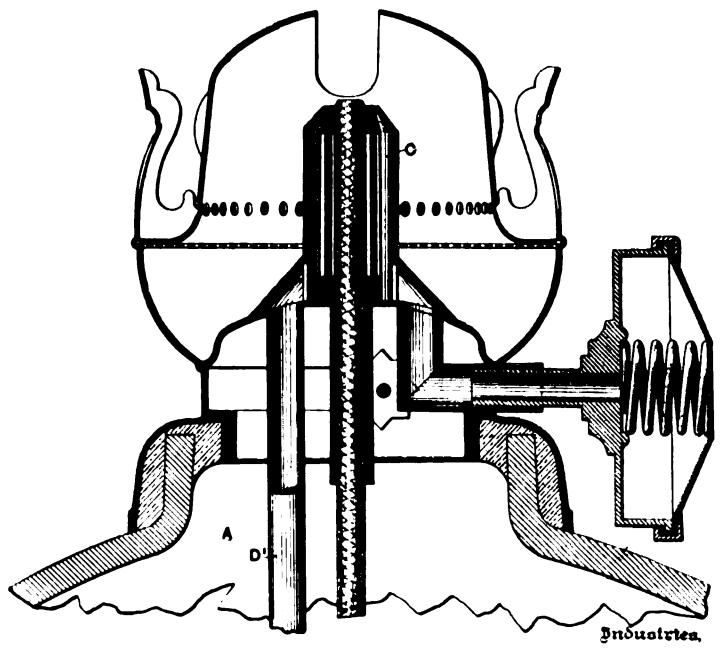

FIG. 4.

R. The supply of oil is stopped entirely on extinguishing the lamp by attaching the lever mentioned to a similar one fixed to a cock in the inlet pipe, so that both levers operate simultaneously. To maintain a small flame for the flash-light, a portion of the wick tube V is cut away at V^2, but a sliding piece W is placed over it, thus restoring the uniformity of the top edge of the tube. This slide is attached by a rod X, kept in position by the spring Y to another rod Z fixed to the lever N. When the wick is lowered the slide is also moved, and that portion of the wick, being unenclosed, remains alight. Raising the wick replaces the slide, and the light is communicated to the entire wick.

The second improvement consists of an addition to the present style of burner by which the "intermediate" oils are rendered available for illuminating purposes by being fed to the wick at the top instead of being drawn up by capillary attraction in the usual manner when light oils are used. The manner of feeding the oil is shown in Figs. 3 and 4. Round the wick tube or case D of an ordinary petroleum burner, which is perforated, a metal jacket C is fixed; inside this is a packing of a certain nature pervious to the oil, but impervious to air without pressure. From this jacket one or two tubes D^1 drop to the bottom of the oil reservoir, a wick being inserted in the wick case and the tubes charged with oil. The flame will be maintained at its fullest power until the whole of the oil is consumed from the reservoir and from the tubes. The tubes are charged by forcing the air from them by a small pump V^1, shown in Fig. 3, or by means of exhaustion by a diaphragm and spring, shown in Fig. 4. The wick may be enclosed, with the exception of the top portion, in a sealed case, and have no contact with the oil excepting through the perforations.

RETORTS FOR VITRIOL WORKS.

PLATINUM stills, at all times costly, have had their value largely increased by the late rise in the price of platinum, and the question of the advisability of their use has had imported into it fresh factors of importance. A manufacturer buying a still for £2,000 had to balance the advantages gained by the use of so costly a piece of plant against the interest that had to be reckoned on its price. Seeing that the price of platinum is now double what it was a comparatively short time ago, the increased expenditure that must be incurred to secure precisely the same advantages as in former days may turn the scale in the opposite direction.

But the investment of a certain amount of capital is not the only matter to be considered in this connection; there is deterioration to be thought of. Provided a cast-iron pan remain sound, few will grumble (except possibly the consumer) at the gratuitous distribution of a little iron mingled with the product which it has aided in preparing; indeed, a faint advantage may accrue from the reduction of its thickness and the consequent greater readiness with which heat may be transmitted through its walls.

Returning to our main proposition, that, in the case of vessels made of materials of no great rarity, there will be small objection to the removal of trifling amounts of their substance in the course of their time of service, it appears that, with the enhancement of the cost of the material, the loss caused by the corrosion of a vessel made of that material may rise until it becomes considerable. Applying this principle to the particular case before us, it is plain that the corrosion of platinum vessels has been at all times a serious matter, and is doubly so now. Even in the laboratory, it is fully recognised that the loss of weight of a platinum crucible or dish in constant use is not only large from a chemical point of view, but may be perfectly appreciable commercially. Turning, then, to large scale operations, we may expect the losses from this source to be worthy the closest consideration.

Data on which to base general conclusions of this kind exist no doubt in plenty in the records of manufacturers themselves, but are often inaccessible, to the great detriment of the particular branch of technology with which they are concerned. Some figures have, however, lately been contributed by C. Heræus to the *Chemiker Zeitung*, which are worthy of attention. The teachings of electro-chemistry lead to the belief that a pure metal will in general be less readily attacked by a corrosive liquid to which it may be exposed than one to some extent contaminated with impurities. The example that at once occurs to one is that of zinc, which is all but unacted on by dilute sulphuric acid if pure, but if of only commercial quality dissolves with rapidity in that menstruum. But the exceptions to this rule are many and weighty. It is generally conceded, although the opposite view has been authoritatively advanced, that pure lead for vitriol chambers is a costly mistake, a small proportion of antimony being considered greatly to increase its power of resistance. It is, therefore, neither surprising to find that the first impression as to what is the proper quality of platinum to be used

Digitized by Google

for stills was that it should be pure, nor astonishing to discover that there is ground for supposing this view mistaken, and that a certain alloy is preferable to the pure metal. Formerly, platinum for stills was required to contain not more than 0·5 per cent. of iridium, and, in spite of the statement current in the text-books that an alloy containing 10 per cent. of iridium was better at least for laboratory purposes, no record of direct experiment appears to have been made until lately. A sample of extremely pure platinum, containing only 0·01 per cent. of iridium, was taken as the basis for experiment, and alloys, composed of 95 per cent. of platinum and 5 per cent. of iridium, and 90 per cent. of platinum with 10 per cent. of iridium, prepared therefrom. These alloys were rolled into sheets, weighed, and exposed in a still used in the preparation of sulphuric acid of 98 per cent. strength for forty days. At the end of this time the test specimens were weighed again, and the loss of weight compared with that suffered by a similar piece of pure platinum. Calling the loss of weight of the pure platinum 100, that of the 5 per cent. alloy was 73, and that of the 10 per cent. alloy 58—a very significant result. There appears, therefore, good reason to suppose that a trial of the 10 per cent. alloy would at least be worth making. With the present high price of platinum the extra cost due to the introduction of iridium is of less moment than heretofore, while the diminution of loss becomes a goal more desirable of attainment. One word of caution may, however, not be out of place: 10 per cent. iridio-platinum is not always quite to be depended upon; vessels made by firms of repute have sometimes been found anything but satisfactory in actual use. Possibly it is not easy to free the iridium from allied metals, such as osmium, that have disagreeable peculiarities, but whatever the cause it is a certainty that this alloy may prove troublesome, and even useless for some purposes.

To some the attack of platinum by sulphuric acid may seem almost incredible, but it is real enough even with the pure acid, and is probably greater when nitrous compounds are present. It is well known that gold is by no means unattacked by nitric acid (especially in the presence of nitrous acid), and indeed such perceptible quantities are dissolved that in recent researches in pure chemistry it has been found necessary to abandon the use of platinum retorts, the joints of which were soldered with gold, in favour of such apparatus as allowed the nitric acid that was being prepared to come in contact with no metal but platinum, and thus maintain its purity. But the order of attackability of gold and platinum by nitric acid appears to be reversed in the case of sulphuric acid. An experiment executed in a manner similar to that already detailed showed that, taking the same standard of comparison as before—viz., the loss of weight of pure platinum as 100—the loss of weight of gold was only 13, or but little more than an eighth of the former quantity. Acting on the result of this experiment, Heræus has taken out a patent for coating the interior of the platinum retorts used in the manufacture of vitriol with gold at the bottom and as far up the sides as the boiling acid reaches. As gold and platinum are at present not far from being the same price, the economy of such a proceeding is obvious. Even in the event of the price of platinum falling to its former level, there will be a large margin, and it is highly improbable that the substitution of the one metal for the other for this purpose will ever prove unprofitable, as, for that to come about, the price of platinum must be only about one-eighth that of gold—*i.e.*, about 10s. an ounce.

Notes.

RAILWAY CARRIAGE COOLING APPLIANCE.

An improved apparatus for providing railway carriages with a cool and pleasant breeze has just been brought out by Mr. George Payne, of the Locomotive Department, Indian Midland Railway. It is fitted under the body of a carriage, is self-revolving, is so arranged that it will catch the air from all directions, and it possesses, according to the *Indian Engineer*, other advantages, one of the most important being that it will keep working for fifteen minutes after the train has been stopped.

A SEWER SCRAPER.

An apparatus has been invented by M. Emil Sokal for the purpose of clearing away the sludge in the sewers of Warsaw, Russia, when the fall is too slight to admit of its being removed by the ordinary means of flushing. The contrivance, states the *Engineering Record*, consists of a wooden template or mould, fitted to the profile of the sewer, and resting on a batten 1½in. thick, which is pointed at the end for the purpose of penetrating and loosening the sludge. The flushing sluice above the portion of the sewer to be cleaned is closed, and water allowed to accumulate. About 6ft. or 10ft. lower down the template with the pointed scraper is set up; the sluice is now opened, and the scraper, which is under the control of a workman, moves on and clears the deposit. If this be very solid and hard, a small shutter in the template is opened and water sufficient to thin it is admitted, or the scraper may be used more than once at any desired spot.

THE DE WILDE-REYCHLER CHLORINE PROCESS.

W. Jurisch, who has made a study of the commercial aspects of this process, to the inception and progress of which we have from time to time referred, considers that it will prove preferable to the Hurter-Beacon process, both on account of the plant being less costly to instal and work, and because of the fact that the chlorine is evolved in such a concentrated form that bleaching powder of full strength can be made from it. In Belgium, Holland, France, and Germany bleach works and paper factories are about to adopt it extensively.

BRITISH GOODS IN INDIA.

We learn from the *Lucknow Advocate* that a somewhat curious movement has been organised in Calcutta, the object being to boycott everything English. A League has been formed, and its members have bound themselves to have nothing more to do with Manchester cloth, Liverpool salt, and English imported goods. The immediate result has been an impulse to the production and sale of hand-made cloth and piece goods of Bombay. If this be carried out it is practically the imposition of a voluntary tariff, and it will be rather curious to observe how far what is supposed to be a feeling of patriotism will counterbalance the tendency to purchase in the cheapest market.

CURIOUS CAUSE OF ELECTRICAL FAULTS.

The London Electric Supply Company find that where they use concentric wires faults suddenly occur. These they find to be due to mice making contact between the earth and the insulated high-pressure terminal. A current passes and blows the fuse, and the burnt remains of the mouse are found. Probably mice are attracted by the warmth of the transformers, which, when not too hot, also attract beetles and other insects. When the mice get near the high-pressure terminal there is an electrostatic force which acts on their antennæ. This attracts their attention, and they investigate the terminal and find that, whether knowledge comes after death or not, death is apt to come first. If such calamities occurred in the United States, the daily press would reek with sensational accounts of the dangers of electricity for months afterwards.

ELECTRICITY AS AN INCENTIVE.

An American inventor, Mr. A. B. Holson, has patented the combination of a battery, an induction coil, and a horse. If the horse is indolent the induction coil is brought into use to inspirit him. This invention should be used in conjunction with that of Mark Twain for obviating the risks attendant on too high velocities when attained by horses attached to conveyances. A small derrick is arranged above the quadruped; and if his velocity, or, as our electrical friends will have it, his resistance, is dangerously increased, in spite of tension applied to the controlling gear, he is elevated till he is no longer in contact with the ground, and his further proceedings are rendered innocuous. It would seem that horses will soon be under more perfect control generally, for, according to our contemporary, *Invention*, Mr. T. Cannon has just patented a form of bit which has a tube and funnel, so that medicine may be readily poured into the animal whether he feels inclined for it or not.

STANDARD THERMOMETERS.

It is well known to thermometer makers that a freshly blown glass bulb contracts slowly in volume for a very long time, and various processes have been invented for hastening this secular contraction. The ordinary process of boiling in oil takes a very long time, and we therefore wish to call attention to some results which have recently been obtained, in which the glass was heated in boiling sulphur. Two experimenters, Messrs. Callendar and Griffiths, have studied the alteration of a bulb of soft German soda glass at the temperature of sulphur vapour. Their bulb at the commencement held 59·710 cubic centimetres, and after a quarter of an hour's immersion in sulphur vapour its volume was 59·574 c.c., showing a decrease of ·136 c.c. The same bulb was then re-heated for two hours at that temperature, and its volume had decreased by ·056 c.c., and after a similar re-heating its volume was 59·505, showing only a further decrease of ·013, at which it remained practically steady. So that a long and tedious operation may be immensely shortened by the use of boiling sulphur. Sulphur may be readily boiled in an iron vessel with the lower end in the fire, and sufficiently tall to condense the vapours. The boiling point of sulphur is 444°—that is, a temperature only slightly below that at which the glass in question softens. This fact explains the observed results. The glass should be in contact with the vapour only, as it is blackened by contact with the liquid sulphur.

INDUSTRIAL ESTABLISHMENTS AT ODESSA.

From a recent official report we learn that there are now upwards of 300 industrial establishments in Odessa, covering almost all branches of industry. Those giving employment to men chiefly are respectively iron foundries, sugar refinery, jute sack factory, tobacco factory, flour mills, &c. The jute factory was opened in 1887 and it has been gradually extending its operations till there are now at work 179 looms driven by two engines, each of 300 i.h.p. One hundred and forty men, 400 women, and 60 children are employed in the works, two years' instruction from two Dundee women having sufficed to initiate them in their duties. Six Englishmen are permanently employed as engineers and technical workmen, the rest being Russians. The works turn out annually from 1,800 tons to 2,200 tons of sacks of various sizes and qualities, besides a small amount of Dutch carpeting. The effect of these works on the importation of jute sacks may be estimated from the following figures:—Imports of jute sacks in 1888, 2,058 tons; in 1889, 1,710 tons; and in 1890, 716 tons.

RAILWAYS IN GERMANY.

The following returns of the results of the working of railways in the German Empire for 1890 have been published by the Imperial Statistical Bureau, and will be of interest for the purposes of comparison with those of the United Kingdom:—

Total mileage	Miles	25,660
Locomotives		13,496
Carriages for conveyance of passengers only		25,404
Waggons for conveyance of general merchandise, minerals, live stock, &c.		237,559
Travelling post-office cars		1,647
Passengers conveyed		337,000,000
General merchandise, live stock, and minerals conveyed	Tons	212,100,000
Average distance which each ton was conveyed	Miles	64⅝
Receipts from passenger traffic		£16,695,000
„ from goods traffic		43,660,000
„ miscellaneous		2,875,000
Total receipts		£63,230,000
Total working expenditure		£34,150,000
Amount paid into the public treasury by the German State lines		26,500,000
Proportion of expenditure to receipts per cent.		54·02
Receipts per mile of railway open—		
From passenger traffic		£667
From goods traffic		1,821
Total per mile		£2,488
Expenditure per mile of railway open		£1,344
Receipt per passenger and per mile		½d.

The total mileage in the United Kingdom is about 20,000 miles, and the number of locomotives about 16,000, the former being less than the corresponding number in the above table, and the latter greater, and these and similar items explain why the expenditure per mile of railway open is only £1,344 in Germany against £1,934 in this country. Another remarkable fact is that more than double the number of passengers are conveyed in the United Kingdom as compared with Germany, but of course a great part of this can be explained by the different domestic habits of the two countries, a comparatively small proportion of the people travelling from country districts into towns, and the facilities for urban travelling being much less extensive than in this country.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

1st June, 1891.

9147. Ellis, A. W. ..... Filtering apparatus.
9166. Taylor, C. ..... Apparatus for singeing textile fabrics.
9167. Taylor, E. ..... Manufacture of ornamental tubing.
9185. Smith, W. ..... Fluid pressure motors.
9203. Tuckfield, C. ..... Automatic steering gear.
9209. Priestman & Priestman Igniting device for gas engines.
9210. Van den Ende, M. J. ... Moulding apparatus.
9213. Ball & Lenggenhager Rotating mechanism for rock drills.
9214. Sigmund, C. ..... Sounding apparatus.
9216. Jefferies, S. ..... Machinery for making bricks and similar articles.
9225. Metcalfe, H. W. ..... Speed indicators for steam engines.
9230. Gestetner, D. ..... Milling or rotary cutters.
9238. Ambler & Branter ..... Machine for moulding hollow ingots.
9246. Day, J. ..... The propulsion of boats and wheeled vehicles by gas or explosive vapour.
9247. Day, J. ..... Gas engines.
9248. Brunner, A. ..... Compound locomotive engines.
9250. Hosking, T. ..... Utilising the waste heat from steam boilers.

2nd June, 1891.

9255. Morrell & Mott ..... Railway rail joint.
9256. Robertson, Orchar, & Robertson ..... Let-off mechanism of looms.
9259. Johnson, J. Y. ..... Station indicators (*Allison*).
9263. Adams, J. H. ..... Gauges for marking and cutting.
9266. Crosland, J. F. L. ..... Steam boilers.
9268. Bosshardt, F. ..... Governors for gas engines (*Huntington*).
9286. Willford, G. W. ..... The manufacture of laminated springs.
9306. Langerfeld, A. ..... Hydraulic embossing machine.
9318. Boult, A. J. ..... Apparatus for charging retorts (*Klonne & Bredel*).
9321. Lake, H. H. ..... Scotch yokes for steam engines (*The Laforge Engine Company*).
9323. Huelser, C. ..... Gasifying contrivance for petroleum motors (*M. Grob & Co.*).
9328. Lake, H. H. ..... Magazines for breechloading weapons (*Bruce*).
9335. Newton, H. E. ..... Printing machinery (*R. Hoe & Co.*).
9347. Osborne, J. H. ..... Screw propellers.
9349. Riggs, L. S. ..... Automatic cut-in valves for air brakes.
9350. Murphy, J. A. ..... Traverse motion for winding cords or yarns on bobbins.
9352. Lefebvre, A. J. ..... The permanent way of railways.
9354. Zube, J. ..... Retort furnaces.
9357. Gough, H. D. ..... Differential pulley blocks.

3rd June, 1891.

9366. Gibbons & Gibbons ..... Apparatus for charging inclined gas retorts.
9369. Evans, W. ..... Screw propellers.
9380. Boyd, J. ..... Machinery for winding yarn or thread.
9381. Rongier, H. ..... Differential pulley blocks.
9396. Frohlich, S. G. ..... Looms for weaving coloured fabrics.
9401. Bell & Bell ..... Mechanical stokers and steam boiler furnaces.
9407. Nuttall, J. ..... Governors.
9422. Larsen, A. C. ..... Centrifugal machines.
9424. Mackay, F. N. ..... Compression pumps for ice or cold producing machines.
9432. Lake, H. H. ..... Couplings for railway vehicles (*Caldwell*).
9438. Garrett, J. W., Jun. ... Hydraulic motors.

4th June, 1891.

9452. Atock, L. ..... Looms for weaving.
9456. Bragg, W. B ..... Bulkheads, or the like, in ships.
9463. Hughes, E. W. M. ..... Manufacture of railway carriage couplings.
9469. Pilkington, S. H. ..... Picking motion for under pick looms.
9473. Broadbent, H. ..... Pneumatic power hammers.
9474. Smith, R. H. ..... Indicators for steam, gas, and other engines.
9475. Brown & Balfe (both of the Firm of Thomas Taylor & Sons, Ld.)... Machinery for preparing yarn.
9484. Hosking, T. ..... Combined feed-water heater, draught inducer, and smoke consumer.
9488. Schmidt, W. F. ..... Looms for weaving.
9489. Oxley, T. ..... Pickers for use in looms.
9498. Cameron, A. ..... Driving pulleys.
9519. Edwards, E. ..... Steam engines.

5th June, 1891.

9543. Hoyer, F. ..... The generation of steam for steam engines.
9548. Watt, Kershaw, & Hargreaves ..... Pickers used in looms.
9549. Thompson, W. ..... Apparatus for drawing fibres.
9550. Ellis, W. I. ..... Gas exhausting machinery.
9558. Watkins, A. A. ..... Hydraulic engine.
9559. Hammesfahr, E. ..... Applying driving belts to pulleys.
9560. Banks, B. R. ..... Machine for casting bullets.
9564. Richard, T. ..... Pumping or raising liquids.

6th June, 1891.

9576. Govan, A. A. ..... Coupling railway carriages.
9579. Soucheire, L. ..... Means of converting reciprocating into rotary motion.
9583. Shone & Ault ..... Machinery for compressing and exhausting air or other fluids.
9599. Von Mertens, F. R. ..... Driving mechanism for the axles of locomotives mounted on turning frames or bogies.
9603. Boult, A. J. ..... Apparatus for automatically supplying feed water to steam boilers (*Laillet*).
9607. James, W. ..... Hydraulic apparatus for transmitting motion to engines and other machines.
9609. Biggs & Thomas ..... Apparatus for cleaning tin or terne plates.
9613. Hulme, S. ..... Roving and similar frames.
9620. Walker, A. G. ..... Railway signalling apparatus.
9631. Owston, W. C. ..... Water circulation and consumption of smoke in furnaces for steam boilers.
9632. Edwards, E. ..... Railways for transporting ships (*Dymcoff*).
9645. Horn, W. W. ..... Rail splice and bolt for railroads (*Weller & Mann*).

ELECTRICITY.

1st June, 1891.

9227. Siemens Brothers & Co., Ld. ..... Telephones (*Siemens & Halske*).
9241. Thompson, W. P. ..... Electric railways (*Harding*).
9245. Linhart & Seitz ..... Telegraphic apparatus.
9249. Rowan & McWhirter ... Electromagnets for holding tools.

2nd June, 1891.

9272. Callendar, H. L. ..... Resistance boxes.
9291. Bishop, A. E. ..... Arc lamps.
9300. Sykes, W. R., Sen. ..... Railway signalling apparatus.

3rd June, 1891.

9403. Raeburn, J., Jun. ..... Insulating appliances.
9418. Macdonald, R. ..... Movable submarine batteries.
9423. Grenfell, H. H. ..... Holder for incandescent lamps.
9435. Lauckert, E. F. H. H. ... Transformer.
9436. Williamson, A. D. ..... Transformer.

4th June, 1891.

9462. Alcock, A. U. ..... Electrostatic switch and phase indicator.
9507. Dayton, C. A. ..... Stop motion for engines.
9522. Stanley, Jun., & Kelly Alternating current electromagnetic motors.

5th June, 1891.

9555. Gwynne, J. E. A. ..... Carbons or electrodes for arc or other lamps.

6th June, 1891.

9606. Thompson, W. P. ..... Apparatus for holding telephone receivers (*Stein, Jun.*).
9627. Abel, C. D. ..... Thermo-electric batteries (*Gülcher & Pintsch*).
9628. FitzGerald, D. G. ..... Negative elements of voltaic batteries.
9637. Alabaster & Gatehouse Automatic cut-out.
9642. Watt, H. ..... Lamps.

CHEMISTRY.

2nd June, 1891.

9280. Frost & Kayser ..... Azo colouring matters and their application for dyeing.
9332. Brochocki, C. T. S. de D. Production of chlorine compounds for bleaching.

3rd June, 1891.

9388. Taylor, M. ..... Apparatus for the production of carbonic acid gas, and the employment thereof in the extinguishing of fire.
9439. Lake, H. H. ..... Collecting the vapours of solvents (*La Société Anonyme des Parfums Naturels de Cannes*).

4th June, 1891.

9457. Parkinson, J. H. ..... Separating oxygen from atmospheric air.

5th June, 1891.

9575. Rylands, D. ..... Process for the manufacture of carbonic acid gas.

6th June, 1891.

9636. Willcox, B. ..... Black azo colours (*Farbenfabriken vormals Friedrich Bayer & Co.*).
9646. Luhmann, E. ..... Production of carbonic acid.

MISCELLANEOUS.

1st June, 1891.

9170. Lamb, G. W. ..... Railway and fog signals.
9171. Luhmann, E. ..... Extraction of gases from fluids.
9193. Jacks, R. ..... Composition for coating ships' plates (*Sharp*).
9194. Blakemore, J. ..... Nuts.
9217. Boyce & Hollier ..... Anchors.
9219. Niewerth, H. ..... Obtaining metals and other minerals.
9224. Wilson & Pirrie ..... Boat disengaging gear.
9237. Brewster, F. W. ..... Supporting, lowering, and raising ships' boats.

2nd June, 1891.

9284. Taylor, J. ..... Belt fastener.
9288. Harding, T. W. ..... Combs for cleaning the brushes of cotton cards.
9325. Starley, J. K. ..... An improved joint.
9333. Collet, A. ..... Manufacturing wood pins and keys for railway purposes.
9341. Rogers, J. H. ..... Manufacture of tin and terne plates.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Gas Engines.—*G. Robson, Sunderland.*—The improvements described relate to gas engines and to other motor engines operating upon like principles. The novelty of the invention is said to consist, substantially, of constructing the cylinder of the engine so as to contain two pistons of equal diameter, but having unequal strokes and working in opposite directions, but actuating the same crank shaft. An engine is described, as an example, which is arranged as shown in the sectional elevation below,

having a motor cylinder A, with a water jacket, mounted on a bed-plate B, in the usual way. In this cylinder, which is open at both ends, are a pair of trunk pistons C D, one of which C operates a crank by a single connecting rod E, the other piston operating by a double connecting rod F a pair of cranks on the same shaft. The piston C has a greater stroke than the other, and the cranks may be set at any desired angle with one another, the angle of 215 degrees being chosen in the example. The gas and air valves may be arranged and operated as may be most convenient. When an explosive mixture is admitted to the cylinder and ignited, the pistons are driven outwards from each other and are returned by the momentum of the engine when the products of combustion are driven out through the exhaust port, and the pistons moving out again, a fresh charge of explosive mixture may be drawn in and compressed upon their return stroke. Steadiness, regularity, and high speed are said to be the characteristics of this arrangement. Claims: A double-piston single-cylinder engine, wherein the pistons travel unequal distances in opposite directions, and actuate one crank shaft, as described; the engine as aforesaid in which the rearmost piston is connected by two lateral connecting rods, and the foremost piston by one medial rod, to the same crank shaft, the cranks of which may be set at any suitable angle to each other.—No. 9496. June 19th, 1890. 6*d*.

Air Compressors.—*H. H. Lake, London.* (*E. Hill, South Norwalk, U.S.A.*)—Formerly air compressors designed to compress air to a very great extent were composed of two single-acting cylinders, a large one being used as the primary compressor, and from which the air was led to a smaller auxiliary cylinder where it was still further compressed. When the compressor was first started the large cylinder would be doing its full share of the work while the smaller one was doing practically nothing; this would cause the machine to run heavy on one side and light on the other. This could be remedied by making the cylinders double-acting, but it was found practically impossible to construct a piston for the auxiliary cylinder which would prevent leakage from one side to the other. With single-acting cylinders, where the power is applied only in one direction, there is considerable loss of power on the return stroke, and the compressor works very irregularly and so produces undue strains on the machinery. This invention is designed to overcome this difficulty, and consists of a combination of double-acting primary cylinders with a pair of single-acting auxiliary cylinders oppositely arranged so that an even resistance is produced in all parts of the machine. The accompanying illustrations show this invention carried into effect, Fig. 1 being a side elevation, and Fig. 2 a plan. A is the steam cylinder, B the driving shaft having two

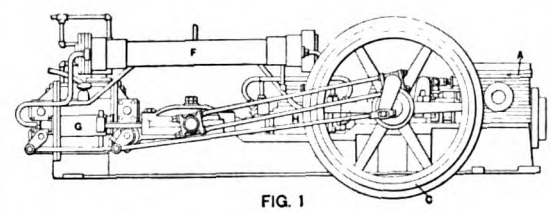

FIG. 1

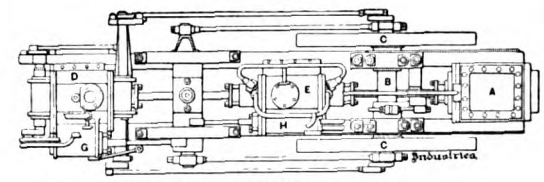

FIG. 2

fly-wheels C C, D represents the first or principal compressing chamber, and E the second compressing chamber. These cylinders are both double-acting and have pistons on piston rods actuated by connecting rods, crossheads, &c., as will be clearly seen in the illustrations. The cylinder D discharges into a receiver, not shown, and from which the cylinder E draws the air and discharges it into a second receiver F. G and H are two single-acting cylinders arranged at the sides of D and E respectively, which have their pistons worked from one of the crossheads in such a manner that while one piston is forcing air the other is being withdrawn. They are of equal area and both draw air from the receiver F and discharge into a common outlet. The inventor describes methods for packing the final compressing cylinders and mentions that in some cases the second or intermediate cylinder may be dispensed with. There are four claims, embracing the following: The combination of a double-acting air compressing cylinder discharging into a receiver with a pair of single-acting cylinders of equal capacity and arranged to operate in opposite directions and drawing air from the receiver. —No. 5254. March 24th, 1891. 8*d*.

Platen Printing Machines.—*A. Morfitt, Nottingham.*—In platen machines constructed according to this invention the locking or holding of the rocking platen is more secure whilst an impression is being taken, and it is possible to obtain a continuous removal and redistribution of the ink upon the inking rollers, to ink the forme more perfectly than heretofore, and to increase the inking surface. An ordinary type of platen machine is described, to which the improvements are applied. A shaft extending transversely across the machine at the rear of the platen is carried in bearings in the main frame, and is caused to receive a partial rotation by means of a cam, lever arm, and spring; a portion of the shaft between its bearings is reduced in diameter, the reduced portion being eccentric to the bearing ends, and being partly flattened to allow the platen frame to pass in close proximity thereto. A suitable cam, above referred to, operates as soon as the platen frame is in position to receive an impression bearing against a fixed stop, and causes the eccentric portion of the cross shaft to rotate into a recess in the platen frame and lock it, and also jam it against the fixed stop. The improved inking appliances consist of rider rollers of tubular form, free to revolve on fixed axles, there being a thread formed on the axle, and a corresponding thread in the hollow of the roller, or *vice versâ*. These rider rollers bear upon inking rollers which are caused to bear upon the type and inking surfaces by means of springs, the rider rollers being free to rise and fall whilst in contact with the inking rollers, and being moved endwise thereon by the screw threads whilst receiving therefrom a motion of rotation, so that a continual redistribution of the ink takes place, even while the ink is being taken off by the type. Claims: Locking the platen by an eccentric partially flattened to allow the platen to pass, and actuated by a cam, roller arm, and spring; also the rider rollers having a rotative and endwise motion upon the inking rollers.—No. 5100. April 2nd, 1890. 8*d*.

Steam Boilers.—*R. G. Ruffles, London.*—In this specification is described an apparatus applicable to steam boilers or other heating appliances, whereby a continuous circulation of the liquid to be heated is provided for by a tubular arrangement through which the water is caused to circulate continuously in an upward direction without liability of any conflicting currents therein, and wherein the main body of water so circulating is surrounded (for any desirable longitudinal extent) by a tubular film, which latter, throughout its length, is exposed to the direct effect of the fire, and is, at its top and bottom parts, in free communication with the said surrounded body of water. This arrangement results in causing an exceedingly rapid conversion of the said film of water into steam, which, continuously escaping into the said surrounded body of water at the upper communication of the film-containing chamber therewith, is effective in inducing (after the manner of an injector) at the head of the inner column of water a continuous pull, and consequently an upward following of that column, and is also resultant in causing an exceedingly rapid upward circulation of the water in the film-containing chamber; owing to the communication existing between the film chamber, at its lower end, and the inner column, a similar upward current is set up in both the film and the inner column. The outer tube is of the Galloway or similar type, the inner tube being fitted into it, closing its upper end, except for the communication with the inner tube by openings in the wall of the latter. The bottom end of the inner tube is provided with a conical deflector, to deflect the water from the centre of that tube, and cause it to pass into the adjacent and concentric inlets to both tubes. Or the outer tube may be connected at its lower end with another tube passing along the flue and being bent upward, so as to draw its supply of water from above the crown of the flue at a point further along than the concentric arrangement is fitted. Claims: The arrangement of double concentric tubes as described, constituting an arrangement for inducing circulation in steam and other boilers.—No. 7121. May 7th, 1890. 8*d*.

Direct-acting Engines.—*H. E. Newton, London.* (*C. C. Worthington, Irvington, New York State, U.S.A.*)—In this invention a vertically arranged duplex engine is especially designed to permit of the use of steam expansively, and also to secure the balancing of the parts, so that the power exerted by the steam pistons will be substantially the same upon the up and down strokes. The invention may be understood by an immediate reference to the illustrations, in which Fig. 1 is a side elevation and Fig. 2 a plan. The engine as therein shown consists primarily of two high-pressure cylinders A B and two low-pressure steam cylinders C D. The cylinders A C form one side of the duplex engine, and the cylinders B D the other side, the two cylinders being connected so as to use steam upon the compound principle. The cylinders are provided with induction and exhaust valves of ordinary construction, and the piston rods G H of the cylinders A B are provided with the usual connections E, by which the valve of each cylinder is operated from the piston rod of the other, in the manner common in duplex engines, the other two piston rods I J being provided with similar connections F, by which the valves of those cylinders are operated in the same manner. Fulcrumed upon the framework beneath the main steam cylinders is a pair of rocking beams K L, which are respectively connected by links M with the piston rods G I and H J. By these means the pistons of the cylinders A C, and the parts connected therewith, are caused to move in unison, one piston and its connected parts making the up stroke while the other piston and its connected parts are making the down stroke, thus causing the weight of the condensing piston and its connected parts to be counterbalanced, or substantially counterbalanced, by the weight of the ascending piston and its connected parts, thus balancing the engine, and causing the available power exerted upon the pistons to be the same upon the up and down strokes. The ends of the beams K L are provided with bearings to receive the ends of the piston rods of two pairs of oscillating compensating cylinders O, pivoted on trunnions supported in suitable bearings, as shown. These compensating cylinders are supplied with a motive fluid under suitable pressure, through pipes which communicate with

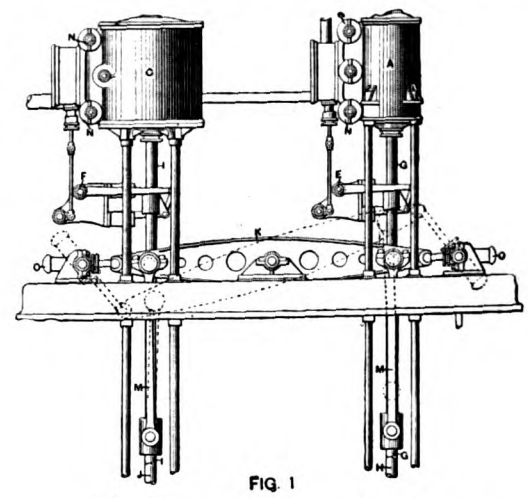

FIG. 1

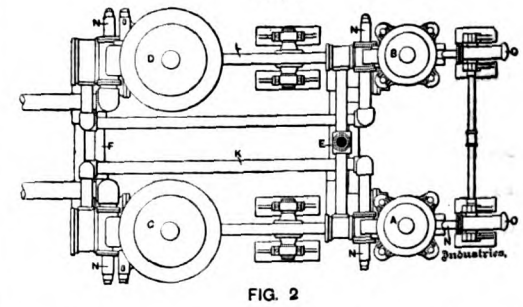

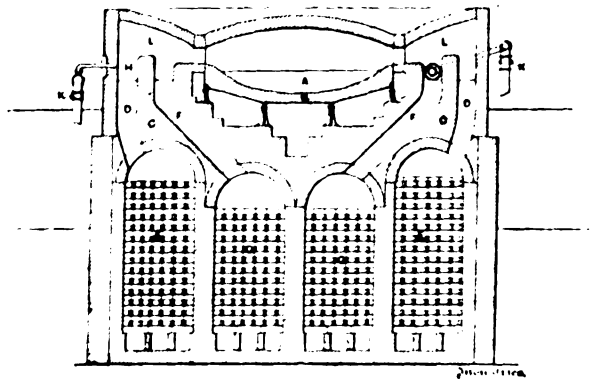

FIG. 2

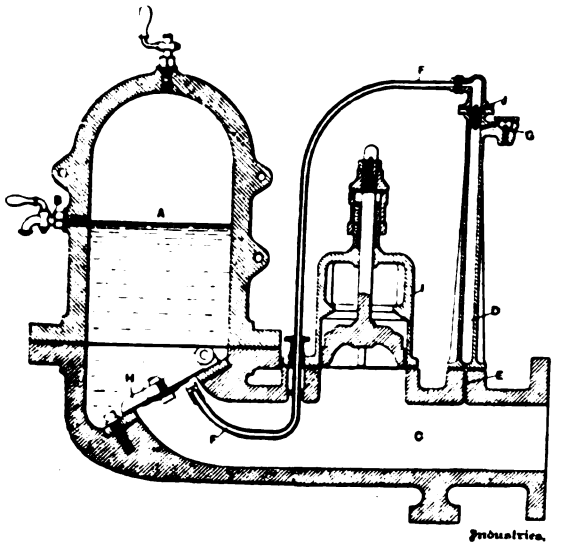
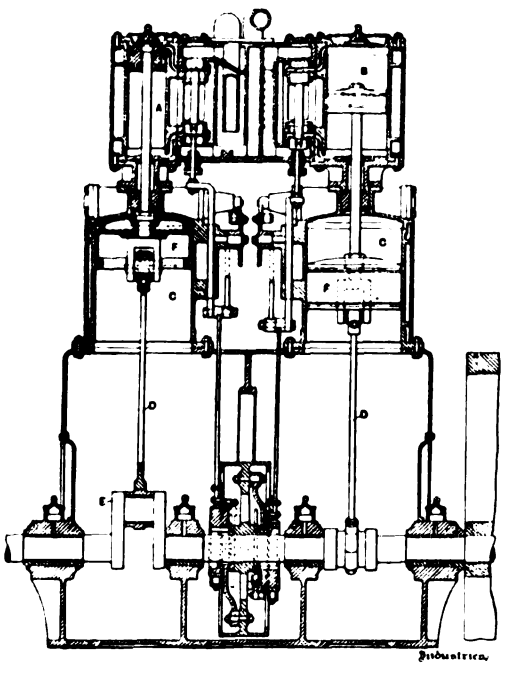
one trunnion of each. The operation of the engine takes place as follows:—Let it be assumed that the piston of the cylinder C has completed its down stroke, and the piston of the cylinder A its up stroke, thereby bringing the compensating cylinders and the beam K into the position indicated by dotted lines; it will be observed that when the beam K is in this position the angle of the rods of the compensating cylinders with relation to the beam K is such as to resist the downward movement of the piston of the cylinder A, and the upward movement of the piston of the cylinder C. During the first parts of the strokes of these pistons the power developed by the steam against their pistons will be resisted by the power developed in the compensating cylinders, but as the pistons of the main cylinders proceed upon their strokes this resistance will, owing to the constantly changing angle at which the piston rods of the compensating cylinders act upon the beam K, be gradually reduced until the pistons of the cylinders A C arrive at the middle of their strokes, as indicated by full lines, at which time the piston

Digitized by Google



rods of the compensating cylinders will be brought into line, and will, therefore, oppose each other, but offer no resistance to the pistons of the main steam cylinders. During the last part of the stroke of the pistons of the main steam cylinders the operation will be reversed, and the pistons of the compensating cylinders will offer a gradually increasing assistance to the main steam pistons. The operation of the compensating cylinders permits of the use of steam expansively, and the engines are therefore provided with suitable cut-off valves N, operated in any convenient manner. Claims: The combination of parts arranged and operating substantially as described and illustrated. —No. 5251. March 24th, 1891. 8*d*.

WATER-GAS FURNACES.—*S. Fox, Leeds.*—The inventor mixes water gas with ordinary producer or Siemens gas in certain proportions for use in the manufacture of iron and steel in connection with Siemens or other gas furnaces, and eliminates



rapidly, by the means described, impurities, by oxidation or otherwise. The inventor states that the necessary temperature for the reduction of metallic substances can be easier attained and maintained than by use of Siemens or producer gas alone. This is carried into effect by leading into any convenient part of the furnace or flue, jet pieces or nozzles for the introduction of the water gas, or a mixture of water gas and producer gas or water gas and Siemens gas, in all of which cases a separate valve is provided to control the water gas, so that the proportion of the gases may be varied to suit requirements. Referring to the accompanying illustration, which shows in sectional elevation the invention applied in two alternative methods to a Siemens gas furnace, A is the furnace bed, B the fire-brick lining, C divisional walls, D admission ports for air, which is previously heated by passing through the checkers E. F are the ports through which Siemens or producer gas is admitted after being heated by passing through the checkers G, H are nozzles for the introduction of the water gas controlled by the valves K. The charge being placed in the furnace bed A, Siemens or producer gas is admitted at the ports F, and mixes in the mixing chambers L with the water gas admitted by the nozzles H, from either one of which chambers L the mixture passes into the furnace. The invention is shown also as applied to a puddling furnace. Claims: The application of water gas in Siemens or other gas furnaces in use with ordinary producer or Siemens gas, or with both, in the manner described.—No. 7827. May 20th, 1890. 8*d*.

HYDRAULIC RAMS.—*W. L. Wise, London.* (*J. Piron, Philippeville, Belgium.*)—To increase the efficiency of hydraulic rams and to render their working continuous and automatic, the inventor provides the ram with an air pump that is automatically worked by water in the pressure pipe of the ram. The pump is provided with two valves, one for admitting air to the pump cylinder and the other to control a pipe leading the air to the air chamber of

the ram. These will prevent any deficiency of air in the ram and reduce shocks due to its working. Means are also provided to automatically regulate the amount of air injected into the air chamber, and consist of a cock placed at about half the height of the air chamber, which allows the air to escape when the water is depressed to a certain level, but will only allow water to pass drop by drop. The accompanying illustration shows the invention in vertical section: A is the air chamber having at its lower end a discharge pipe (not shown in the figure). This chamber is provided at B with an automatic regulating cock as before described. To the pressure pipe C is secured a vertical tube D, constituting an air pump cylinder, which communicates with the pressure pipe by means of a small orifice E. The upper end of the vertical tube D has a non-return air valve J, which controls communication through the pipe F, the other end of which passes into the pressure pipe C and terminates under the air chamber with a non-return valve. The air pump is provided with a vacuum valve G which permits air to enter the tube but will not allow it to return. The pressure pipe is provided with a flap valve H, immediately below the air chamber A, and also with an escape valve I of the mushroom type. When not in action the escape valve I is open; water flowing into the pressure pipe closes the escape valve by momentum, opens the flap valve H, and flows into the air chamber. Water under pressure also enters the vertical tube D, forcing the air through the pipe F into the air chamber. The escape valve I falls by gravity, and the water falling out of the vertical tube D draws in a further supply of air through the valve G. Claims: Causing air to be admitted into the air chamber of hydraulic rams by an air pump worked automatically by the water and the apparatus as described and shown.—No. 9729. June 23rd, 1890. 8*d*.

STEAM ENGINES.—*S. Wilcox, New York.*—In multiple-expansion engines the inventor embodies a series of single-acting low-pressure cylinders axially aligned with the double-acting high and intermediate cylinders, and having connected pistons coupled to a single crank, the steam distribution to the series of cylinders in alignment being governed by the same valve gear. The accompanying illustration shows in vertical section the invention applied as a triple-expansion engine. A is the high-pressure cylinder, B the intermediate cylinder, and C C two single-acting low-pressure cylinders. The vertical space occupied by the single-acting cylinders C, the inventor claims, is only equal to that occupied by the usual cross-heads and guides, so keeping the aggregate height of the engine normal with those of the usual construction. The cylinders C may form a part of the frame of the engine, and support the cylinders A and B above them. This lowers the centre of gravity of the engine, and allows the connecting rods D to be of increased length without rendering the engine top-heavy. The frame may be of any convenient form, and is shown in the illustration as being of the box form, and the cranks E may be fixed at the usual angle—*i.e.*, 90 degrees. The pistons of the

high and intermediate cylinders are connected by piston rods with the pistons F of the low-pressure cylinders, which pistons F have their bearing surfaces elongated to afford proper resistance to wear due to the side thrust of the connecting rods G. H H are piston valves for the cylinders A and B. The low-pressure cylinders have induction and eduction valves of the "Corliss" type (not shown). The receiving chambers have separators for eliminating condensed steam during the passage of the steam from one cylinder to another, and suitable drip valves are provided for removing the accumulated water from the wells of the separators. There are six claims, covering a compound engine consisting of a high-pressure cylinder or high-pressure and intermediate cylinders connected with a single-acting low-pressure cylinder or cylinders arranged in common axial alignment.—No. 1437. January 27th, 1891. 11*d*.

FURNACE BARS.—*W. Fraser, Birmingham.*—This invention relates to hollow furnace bars, through which air is supplied for combustion; instead of casting the bars in the ordinary manner, with an air passage cored out in them, the lower part of the bar is made of sheet metal, the upper portion being cast separately in a chilled mould and slipped on to the lower sheet-metal portion, which is bent into a trough shape to receive it. One part of the cast portion stands above the trough sides, and another part projects between them, the sides of the trough being held together by rivets or otherwise, and fitting into grooves recessed into the underside of the bar. The cast portion of the bar may be lightened by having a sheet-metal backbone, which is placed in the mould and has the body of the bar cast round its upper edge. It is intended that the whole of the air supply to the furnace should be taken through the hollow bars, which are supported by a hollow dead-plate and hollow bearers. The bridge is also hollow, being formed of sheet metal faced with firebrick, and having two chambers, one at the back and the other at the front of the bridge. The ashpit is closed, and the air supply is led through the dead-plate and bars into the front chamber of the bridge, being led over a central division plate and thence through the rear portion of the bridge, so that it may be thoroughly heated before it is finally discharged into the ashpit, at the lower portion of this front chamber. Or the heated air, instead of being discharged directly into the ashpit, may be led into channels formed in the brickwork lining the flue, and delivered at various parts of the fire and behind the bridge. The channels are controlled by suitable regulators hung below the fire-bars so as to divide the ashpit into three sections. The sides of the grate are lower than the centre, so as to obtain an increase of grate surface. An improved bearer for firebars is described, consisting of loose serrated pieces, which may be bolted on to each side of a serrated portion of the bar, in various positions, so as to shorten or lengthen it to fit various sizes of flue. Claims: A furnace constructed with air channels in the sides or lining of the furnace for conveying air from the bridge to the ashpit below the furnace; the arrangement of hollow dead-plate, hollow bars, and hollow bridge to heat the supply of air for combustion; the hollow bar formed as described; the firebar bearer, with extensible ends.—No. 5616. April 14th, 1890. 8*d*.

RAILWAY CHAIRS.—*A. J. Boult, London.* (*G. W. Wells, Worcester, Mass., U.S.A.*)—Chairs for supporting rails are so made under this invention that when in position they are firmly held by interlocking portions, and the use of nuts and bolts is avoided, rendering the chair, according to the inventor, practical, cheap, and efficient. Referring to the accompanying illustrations,

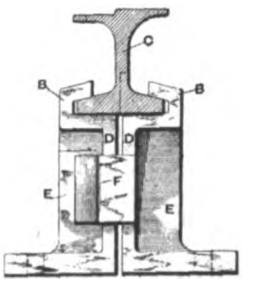


FIG. 1.

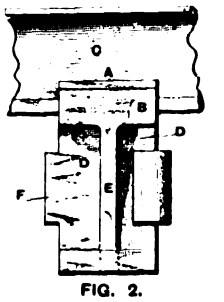

FIG. 2.

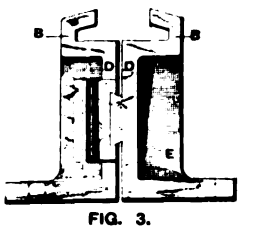

FIG. 3.

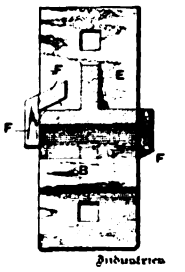

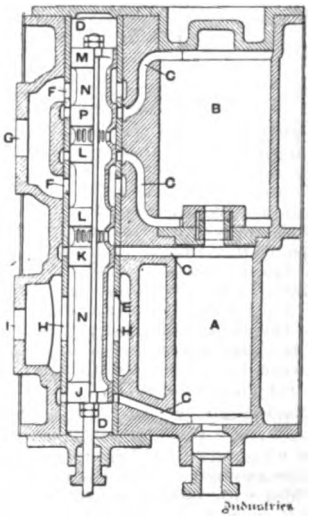

FIG. 4.

Fig. 1 shows an end elevation, Fig. 2 a side elevation, Fig. 4 a sectional plan, and Fig. 3 a modification, of an improved chair, clamping and supporting a rail. A A represent the two similar parts of which the chair is composed, each having at B a head to grip the flange of the rail C, and being composed in the centre of a T-shaped section with ribs D E. From the rib D extends a hook F, which is adapted to catch on the rib D of the opposite portion. The hooks F are bevelled or tapered as shown in Fig. 4, and the manner of fixing the rail is as follows:—The parts A A are locked together, each head gripping the opposite flange; the sections are then spiked to the sleeper, the spikes being driven in slightly oblique directions to force the two sections close together. The chairs may be made of extra width to support the ends of two rails meeting. Another modification is described, in which a dove-tail locking mechanism is substituted for the hooks. Claims: A railway chair, composed of two sections, each section having an inclined or oblique interlocking portion to engage the other section.—No. 5970. April 7th, 1891. 6*d*.

SLIDE VALVES.—*S. L. Brunton & J. G. Statter, both of West Drayton.*—The valves here described are of a kind suitable for various forms of reciprocating double-acting steam or other expansive fluid engines such as gas engines when worked by the expansive force of the gas alone. Referring to the accompanying illustration, which shows in vertical section the improved valve

fitted to a double-acting tandem compound engine, A is the high-pressure cylinder placed below the low-pressure cylinder B. Both cylinders have ports C of the usual form communicating by annular openings with the valve chest D of circular form and common to the two cylinders, and preferably fitted with a liner E having suitable perforations opposite the annular port openings. In addition to these four openings, the liner has three other

Digitized by Google

openings, two of them, F F, communicating with the exhaust outlet G, and the third H with the steam inlet I. The valve N is of the hollow piston type, with or without spring rings; the part of the valve from J to K regulates the admission and exhaust to and from the high-pressure cylinder A, and the part from L to M serves the same functions for the low-pressure cylinder B, and the two pistons L and M separate the exhaust steam from the low-pressure cylinder B from that of the high-pressure cylinder A. The valve is provided with suitable lap and lead as are ordinary slide valves. The interior of the valve N and the annular spaces between the pistons K L and L P form the intermediate receivers for the steam on its passage from cylinder A to B. The action of the valve is as follows:—Steam is admitted to the annular space between the pistons J and K, and is led thence alternately to the top and bottom ports of the high-pressure cylinder by the movement of the valve N, the exhaust steam from the high-pressure cylinder passing into the inside of the valve N, from whence it is supplied to the low-pressure cylinder by means of perforations leading into the annular space between the pistons L and P, the exhaust steam from the low-pressure cylinder B passes out into the annular spaces between the pistons L L and P M, and so to the exhaust outlet G. The capacity of the intermediate receiver can be varied to suit requirements. The inventor describes various modifications of the valves, and their application to compound engines with cylinders side by side, and to a triple-expansion engine with the cylinders arranged one above another. Claims: The employment of a cylindrical valve of the piston type to expansive fluid engines, the valve working in a valve chest of circular form, and common to two or more cylinders, and serving for the complete distribution of the expansive fluid to and from all the cylinders in connection with the valve chest.—No. 9213. June 14th, 1890. 11*d*.

RAILWAY COUPLINGS.—*N. Knowles, J. W. Webster, & A. Dornan, all of Bolton.*—By means of this coupling it is claimed that the vehicles can be coupled or uncoupled from either side. A cross-bar or pivot is connected to the draw-bar or other suitable part of the vehicle, and has a hook and link one on each side of the ordinary hook, they being connected to the cross-bar in such a manner as to allow for lateral and vertical oscillations of the vehicles. Under each end of the vehicle a shaft is suitably mounted having levers attached for placing the hooks and links in position to lock or couple on to other vehicles. When the hook is raised into position for locking, it is held by a spring or its equivalent. The link is furnished with a slotted fixing to hold it in position when coupling, or to hold it out of position when not required. Each hook has suitable curved guides to ensure the connecting link being guided correctly in position for coupling. The shaft under the ends of the vehicle is actuated by a lever to uncouple, the hooks dropping clear from the links and leaving the links in a position for recoupling. The accompanying illustrations show the application of the invention, Fig. 1 being a longitudinal elevation, and Fig. 2 a plan. A A

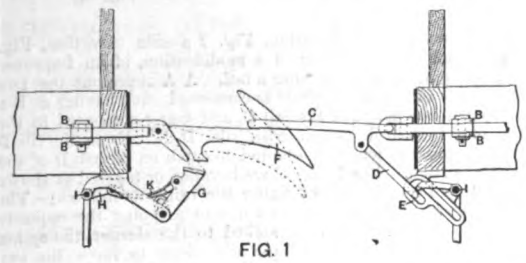

FIG. 1

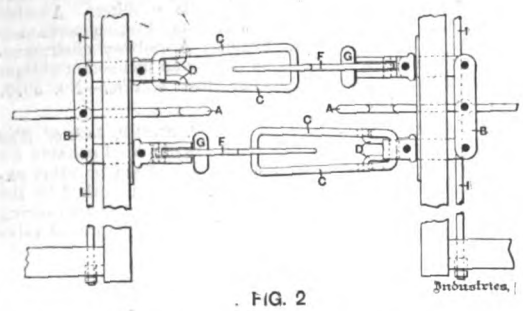

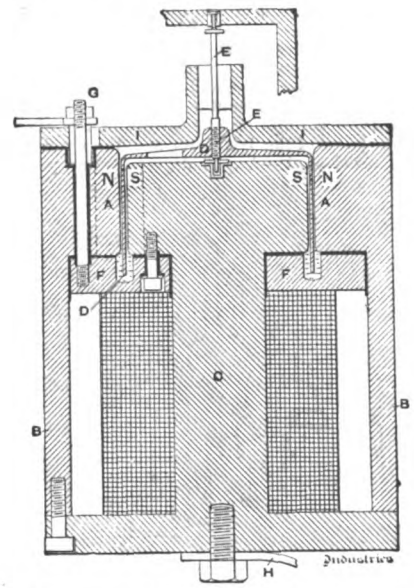

FIG. 2

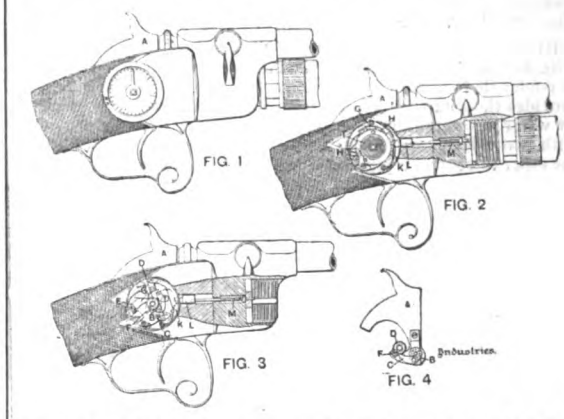
are ordinary hooks, B B the cross-bars, each connected by means of a pin with a draw-bar. Each cross-bar has attached to it by means of a clip-piece and connecting link the coupling link C, provided with supporting arms D, these being mounted loosely in a slotted fixing E secured to the buffer beam. The cross-bars B B have at the opposite side to the coupling link C, the hook F, which is raised by the pivoted support G, and held in position for coupling. This support G is connected with the lever H on the shaft I by the rod or spring K. An important feature of this invention is that vehicles can be uncoupled without stopping the train, it being effected simply by slackening speed and dropping the supports for the hooks. Claims: Combination of the coupling hook, with the support or lever actuated by a lever and spring or rod from a shaft operated outside of each vehicle, and a coupling link, each being provided with means for raising it into position for coupling.—No. 10779. July 11th, 1890. 8*d*.

HOT BLAST STOVES.—*J. T. King, Liverpool.* (*H. Kennedy, Sharpsburg, Penn., U.S.A.*)—This invention relates to vertical hot-blast stoves which are heated by the combustion of waste gases from the furnaces, and are utilised to heat the blast. These stoves are provided with valves for reversing the currents by which they are traversed, so that at one time the waste heat from the furnace is passing through the stoves in one direction, and, later, the blast of air from the blowing engine is being forced through them in the opposite direction into the furnace. They are used in couples, so that while the waste heat is passing out through one or more, heating them up, the blast is being forced in through an equal number which have been previously heated as aforesaid. When one set becomes heated and the other cold, by the currents passing through them, the valves are reversed, and the currents pass in the opposite direction. The inventor claims: In a hot-blast stove, the combination of a pair of flues separated by a vertical flue wall, and communicating at the upper portion of the stove, or at the crown of the stove above the flue wall, said flues having air and gas inlets at their bases, a common outlet at the top, and an air blast inlet and outlet to and from which the air passes in series through the flues.—No. 8952. June 10th, 1890. 8*d*.

ELECTRICITY.

SUPPLY METER.—*J. Perry, London.*—This invention is based on the theory:—If an electric current is caused to pass through a mass of electrically conducting liquid in proximity to a magnet, in almost any position of the arrangement the liquid particles will be set in motion and continue in motion so long as the current flows. If a solid body, being free to move, touches the liquid, it will also be set in motion, and the inventor discovers that if the magnetic field is maintained constant and the motion is everywhere slow, the velocity of motion at any place is proportional to the current, and by suspending a solid body in the conducting liquid and making it free to impart motion to a train of wheels an electric supply meter is obtained whose only defects are due to solid friction. In all cases the inventor keeps the magnet as constant in strength as is possible, whether it be a permanent magnet or an electromagnet. In the latter case, it must be separately excited, and not excited by the current to be measured. The accompanying illustration shows one form of the

invention. A B C is a tubular magnet having at its upper ends concentric poles N N S S. A concentric cylindric vessel of copper D rotates in the space between the poles, and has attached at its upper end a spindle. An insulated copper ring F, filled with mercury, is fixed at the bottom of the space between the poles, and has a current passing into it and the mercury by the supply conductor G, from whence it passes through the cores of the magnet and leaves by the conductor at H. When a current passes the copper vessel is rotated because it is in a magnetic field, and has the current passing through it, and it also has a tendency to rotate through the rotation of the mercury. One or both of the cylindrical poles have a number of gaps, so that the magnetic field varies and produces a resistance of motion due to Foucault currents. In the claims the word "armature" is used to denote the solid moving body in a motor, whether current pass through it or not, and the claims include the following:—The use of an armature shaped like a hollow cylinder of conducting material or not, immersed in mercury, through which passes an electric current; the use of magnetic pole pieces, the polar surfaces being arranged in surfaces of revolution, and the supply meter as shown and described.—No. 7219. May 9th, 1890. 8*d*.



MANDRELS.—*F. E. Elmore, Leeds.*—In specification No. 4499 of 1877 is described a method of manufacturing tubes and other cylindrical articles by electrolytically depositing metal on a revolving mandrel, and burnishing the metal as it is deposited. This invention relates to the construction of mandrels for that purpose. The body of the mandrel is a thin but stiff metal tube coated with a metal or substance which is easily fusible, and which, when cool, sets to a firm consistence. This coating may be applied in various ways, but the following method is preferably adopted:—The tube to be coated is caused to revolve as a roller nearly in contact with another roller, and in the gap between the two rollers is placed the material of which the coating is to be formed. The mandrel tube is kept cool by circulating water, and the adjacent roller is kept hot by steam or otherwise so as to melt the coating material which adheres to the cold mandrel, and is smoothed and polished off by the hot roller. When the coating is of a bad conductor of electricity it is pricked through in numerous places to the metal of the mandrel. When other substances than fusible metals are used to form the coating, the surface thereof is covered with plumbago or other conducting substance. After the metal is deposited on the coated mandrel to the required thickness, the mandrel is heated sufficiently to melt the coating, whereupon the mandrel can be readily withdrawn from the shell deposited on it. Gelatinous or gummy material mixed with conducting powder may be employed to cover a tubular mandrel which is perforated with numerous holes and closed watertight at the ends. After deposition, liquid solvent attacks the coating through the perforations and dissolves it, facilitating the removal of the core. Or the wax coating may be mixed with salt, which, when dissolved out, leaves the coating porous. Claims: A mandrel for the electrolytical deposit of tubes, consisting of a metal tube coated with fusible metal applied and polished by means of a roller; the use of other fusible material, a non-conductor, perforated, and covered with conducting substance, such as plumbago; a metal tube mandrel coated with wax mixed with salt; the gelatinous or gummy coating mixed with a conducting powder.—No. 7932. May 22nd, 1890. 6*d*.

CHEMISTRY.

OBTAINING METALLIC ZINC.—*E. Edwards, London.* (*T. Lange, Brieg, Germany.*)—The present invention consists in making use of a solution of zinc oxide in the form of sulphite instead of sulphate, the presence of sulphurous acid acting beneficially with regard both to the chemical and electrical effects. Sulphurous acid instead of sulphuric acid is used, owing to its property of being readily converted to sulphuric acid by the absorption of the oxygen set free in the bath by the electric current. The resulting sulphuric acid rises to the surface of the bath and may be removed. By the decomposition of the sulphite of zinc (sulphurous acid and zinc oxide) the metallic zinc is freed from its oxygen which passes to the sulphurous acid at the cathode in the bath, and converts it by its addition to sulphuric acid. The chemical combination of zinc with sulphuric acid shows a heat of combination representing 103,230 units of heat, and that of zinc with sulphurous acid only 71,070 units, so that there is a saving in the decomposition of the sulphite of 32,160 units, or nearly one volt less current energy as compared with the decomposition of the sulphate. It follows, therefore, that the electrical deposition of zinc from its sulphite requires 30 per cent. less power. If, therefore, for the production of 1,000 kilos. of zinc per diem from its sulphate at 2·5 volts, about 170 horse-power is necessary, then for the deposit of the same quantity from the sulphite at 1·7 volts, only 120 horse-power will be required. If no sulphurous acid in the form of gas is available direct from the roasting furnace of the ore, it can be obtained in a liquid form in suitable vessels and used for the purpose described. Claims: The process of obtaining metallic zinc from a solution of sulphite of zinc by electrolysis, whereby sulphuric acid is formed as a by-product, substantially as specified.—No. 8716. June 5th, 1890. 4*d*.

MISCELLANEOUS.

COMPRESSED GAS GUNS.—*J. S. Wallace, Belfast.*—The appliance described below is designed for use with guns or apparatus worked by compressed air or gas, to give an indication of the quantity of gas or fluid used, and to show what remains available in the reservoir. In applying this invention to a gun, a counter is connected with any convenient part of the mechanism so that the counter will be operated each time the gun is fired, and so register on a dial the number of such discharges and the amount of available power left, so that the user can readily ascertain when the reservoir will require recharging. The counter is preferably provided with an automatic arrangement to return the pointer to zero upon the removal of the reservoir for recharging. The operation is described with reference to the accompanying illustrations, which show the invention applied to a "Giffard" gun, Fig. 1 being a side elevation, Fig. 2 a similar view partly in section, and Fig. 3 a similar view to Fig. 2 with the reservoir and parts of the registering device removed, and Fig. 4 being a detail. When the hammer A is cocked, the arm or crank B (see Fig. 4) is turned through a small angle drawing back the pawl C so as to engage with a fresh tooth in the ratchet wheel D, the said ratchet wheel being kept in position by the pawl E. When the gun is discharged the pawl C causes the ratchet wheel D to

turn; this gives a rotary movement to the cam or wiper F, which engages with one end of a lever G, the other end of which acts on the ratchet wheel H, which is attached to a spindle, and thus operates a pointer on the outside of the stock. The movement of the ratchet wheel H also winds up a coiled spring I, which, when the reservoir is removed, returns the pointer to zero, the ratchet wheel H having the pawl K and the end of lever G raised free from it by means of the piece L and spring M. Means are also described for preventing the apparatus from registering in the event of the hammer being put down without discharging. Other modifications are described and illustrated. Claims: The method of indicating the quantity of compressed gas that has been used or remains to be supplied in the reservoir of a gun or other apparatus; the employment of a counter driven by the hammer or other moving part; the combination of a suitable alarm to be set in action when the reservoir is nearly empty, and the before-mentioned method of returning counter to zero upon removal of reservoir.—No. 10456. July 5th, 1890. 11*d*.

Copies of the British specifications may be obtained on application to SIR HENRY READER LACK, *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED HELIX-FORMING MACHINE.

THE accompanying illustrations, Figs. 1, 2, and 3, represent a part plan, general view, and a side elevation of an interesting machine which has recently been patented by Mr. J. Laidlaw, of the firm of Messrs. Watson, Laidlaw, & Co., engineers, Glasgow, who are the makers of the machine. This machine is intended for giving a helical form to straight bars. The bars are bent by passing them through a series of rollers, of any number in the series, but preferably three. One of the rollers is carried on the end of a shaft. The upper or neck bearing of this roller serves as an axis for a turntable, which carries one of the rollers at a determined distance from the revolving centre of the turntable. The third roller is carried on a short shaft running in a bearing cast on the framework, and located immediately underneath the turntable. There is a slot in the turntable to allow this third roller to come into suitable position, and at the same time permit of the turntable being moved round as much as is required. It will be seen that since the axis of the first and the axis of the third roller carried from below the turntables have fixed centres, the roller carried upon the turntable may readily be moved into any suitable position relative to the other two rollers to obtain the required curve. Suitable grooves are made in all the rollers to suit the section of the bar to be operated upon. A suitable roller or guiding surface is attached to the table in such a position that the curved bars, when leaving the rollers, are forced over it to give them the required helical form. Referring to Figs. 1 and 3, B, C, and D are the three rollers, of which B is carried on a shaft E, whose upper or neck bearing forms the axis for the table F. The roller C is supported on and moves with the table, and is therefore always at a constant distance from the roller B. The third roller D is carried on an independent shaft which projects through the slot G in the table. It will thus be seen that, by turning the table through a portion of a revolution, the distance between the rollers C and D can be varied at will. A rack Y is formed on the periphery of the turntable, so that the turntable, with the roller it carries, may be turned by means of the hand-wheel H and worm-wheel I. The position of the roller C relatively to the rollers B and D can thus be adjusted to suit the curve into which the bar is to be formed. The rollers are grooved as shown to suit the section of the bar to be operated upon. A guiding surface J is formed upon or fixed to the turntable in

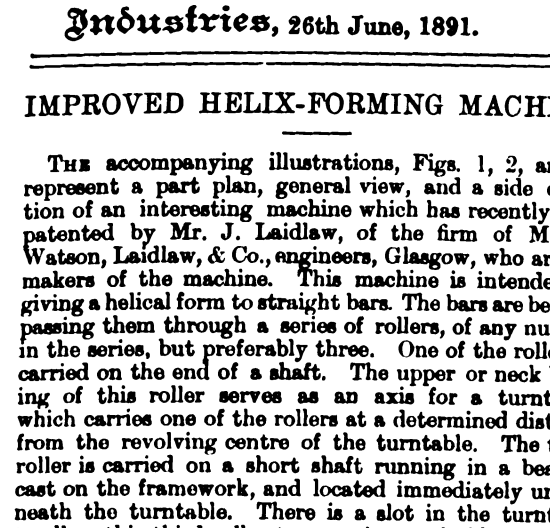

FIG. 1.—PART PLAN.

order to set the bar up into the helical form after it passes through the bending rollers. The rollers B, C, and D are actuated by reversible gearing beneath the table, as shown in Fig. 3, the roller B and spur-wheel K being driven by the worm and worm-wheel L M, the said spur-wheel K gearing with the spur-wheel N, which actuates a toothed wheel on the axis of the roller D. The wheel O, on the shaft of the roller C, also derives motion from the spur-wheel K.

AN IMMENSE CONGRESS.

THE Americans always seem ambitious of having the biggest things of all kinds on earth, and they seem determined that the Chicago Exhibition of 1893 shall, at least as regards size, exceed everything that has been attempted before in the way of exhibitions. That under the circumstances was to be expected, but the latest addition to the programme of the Exhibition is one which is almost calculated to take away one's

IMPROVED HELIX-FORMING MACHINE.

CONSTRUCTED BY MESSRS. WATSON, LAIDLAW, & CO., ENGINEERS, GLASGOW.

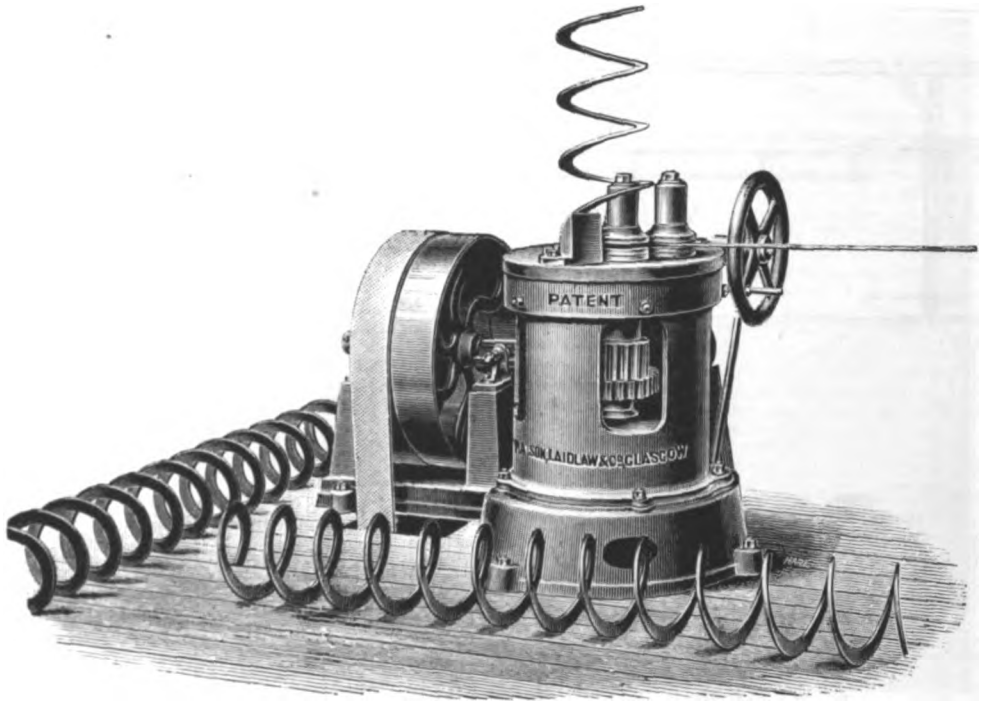

FIG. 2.—GENERAL VIEW.

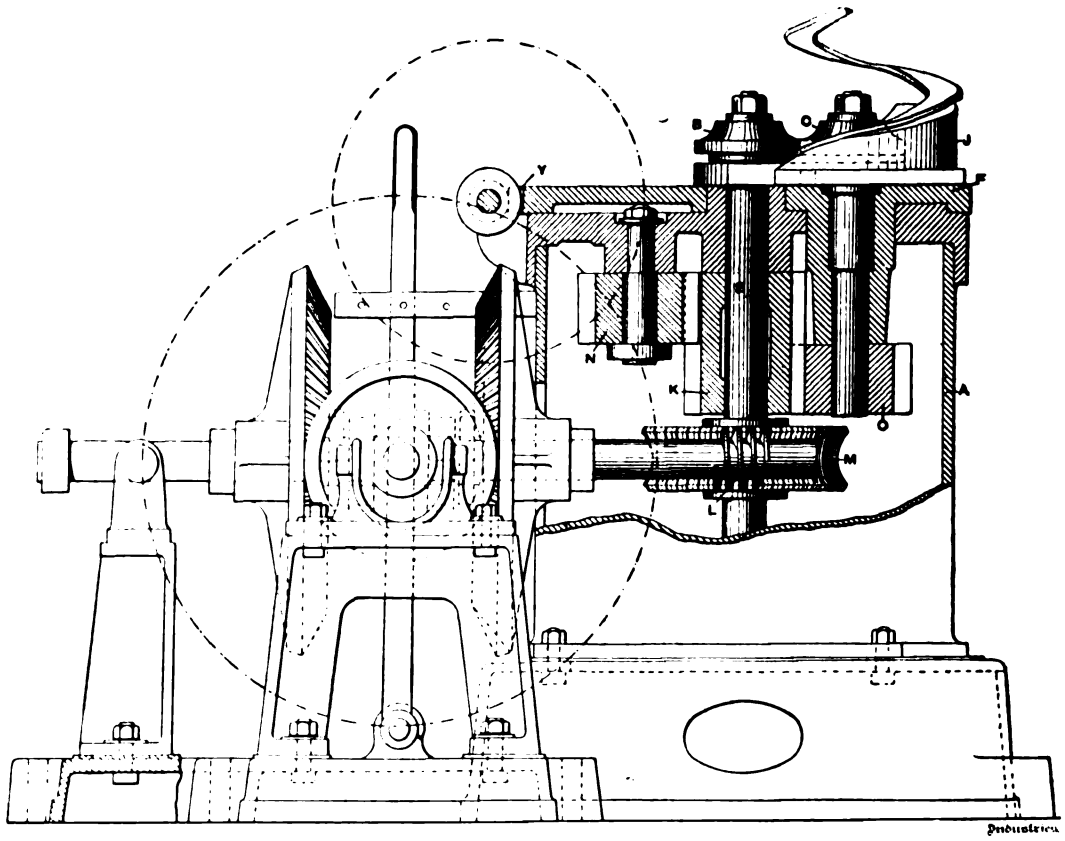

FIG. 3.—SIDE ELEVATION.

breath. They are determined to have the biggest thing in congresses. At the Paris Exhibition there were a considerable number of conferences or congresses, which seemed very complete on paper, but which as a rule did not attract large meetings. The majority of people who visited the Paris Exhibition went to enjoy themselves, and did not allow very serious study to interfere to any great extent with their pleasure, so that very often the conferences were attended only by a few enthusiastic individuals who were responsible for their arrangements. Undeterred by this, the Executive Committee of the Chicago Exhibition have appointed a World's Congress Auxiliary to arrange for the holding of international conventions on all subjects under the sun, the idea being to mark the intellectural progress of the world just as the Exhibition is to illustrate its material and mechanical advancement.

Already considerable progress has been made with the arrangements, and a large number of committees have been appointed to see them carried out. The subjects which are to be discussed seem to cover the whole field of human activity, not only in science and industry, but in connection with several political and religious questions. Particular attention is to be paid to international relations, and the grounds of fraternal union in the language, literature, domestic life, religion, science, art, and civil institutions of different peoples. A provisional programme has been drawn out arranging a series of meetings from the beginning of May till the end of September, embracing almost every conceivable subject, so that all classes of visitors will be certain to find something to interest them. If the Congress is successfully carried out, it should be the means of collecting an immense amount of information. Our only fear is that its very bigness may prevent it from being of much practical utility, and that the records of its proceedings will be so ponderous that a crane will be required to deal with them.

THE GARRUCHA AERIAL ROPEWAY.

(*For description see page* 603.)

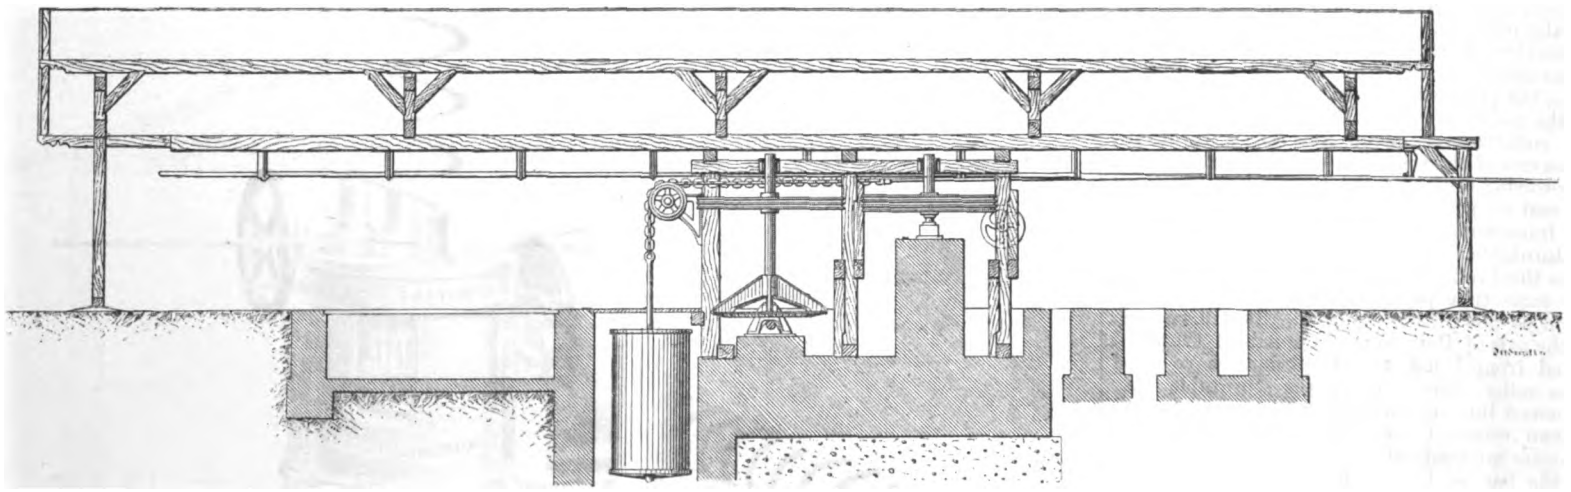

FIG. 14.—LONGITUDINAL SECTION OF ANGLE STATION.

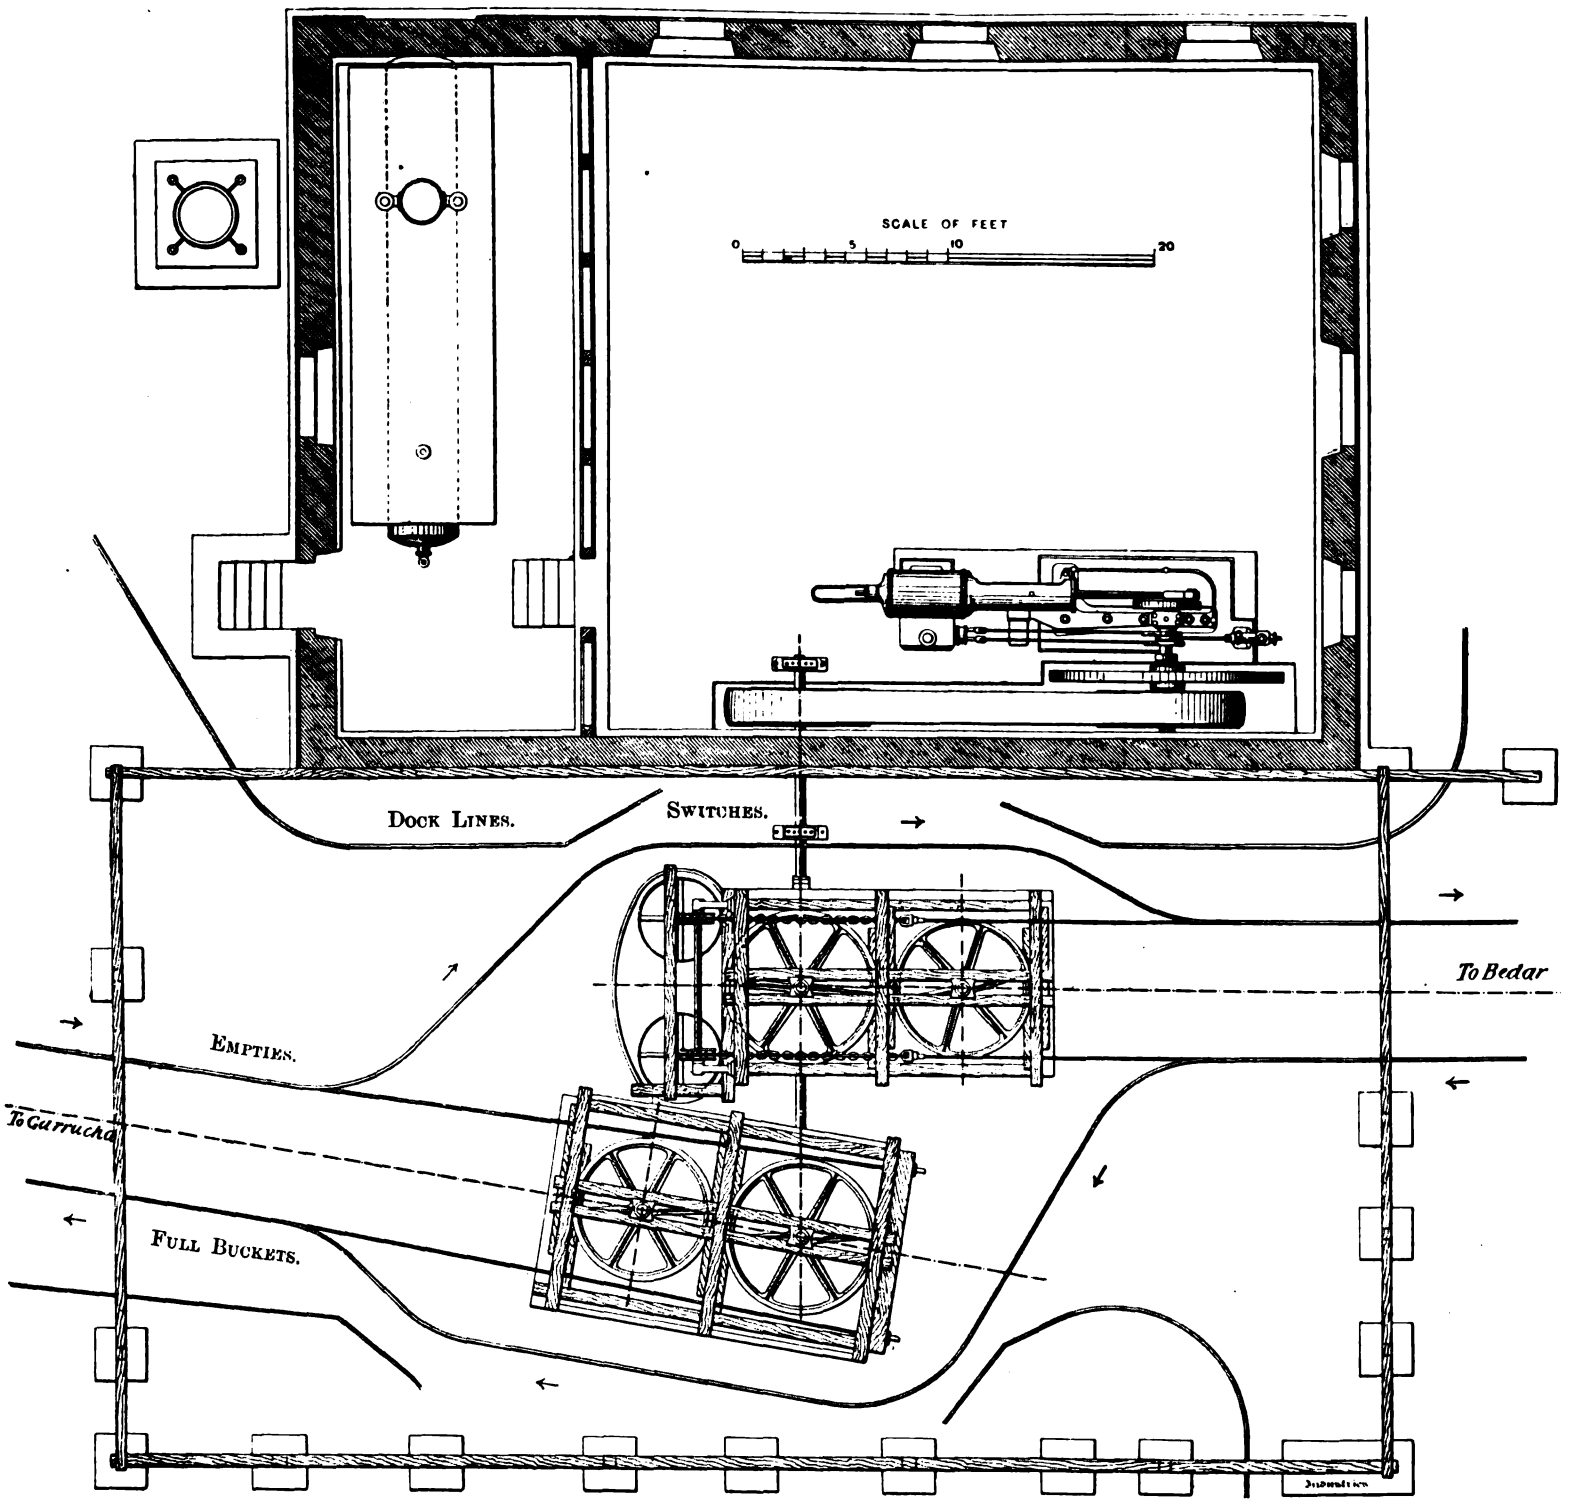

FIG. 15.—SECTIONAL PLAN OF ANGLE STATION.

Digitized by Google

THE GARRUCHA AERIAL ROPEWAY.

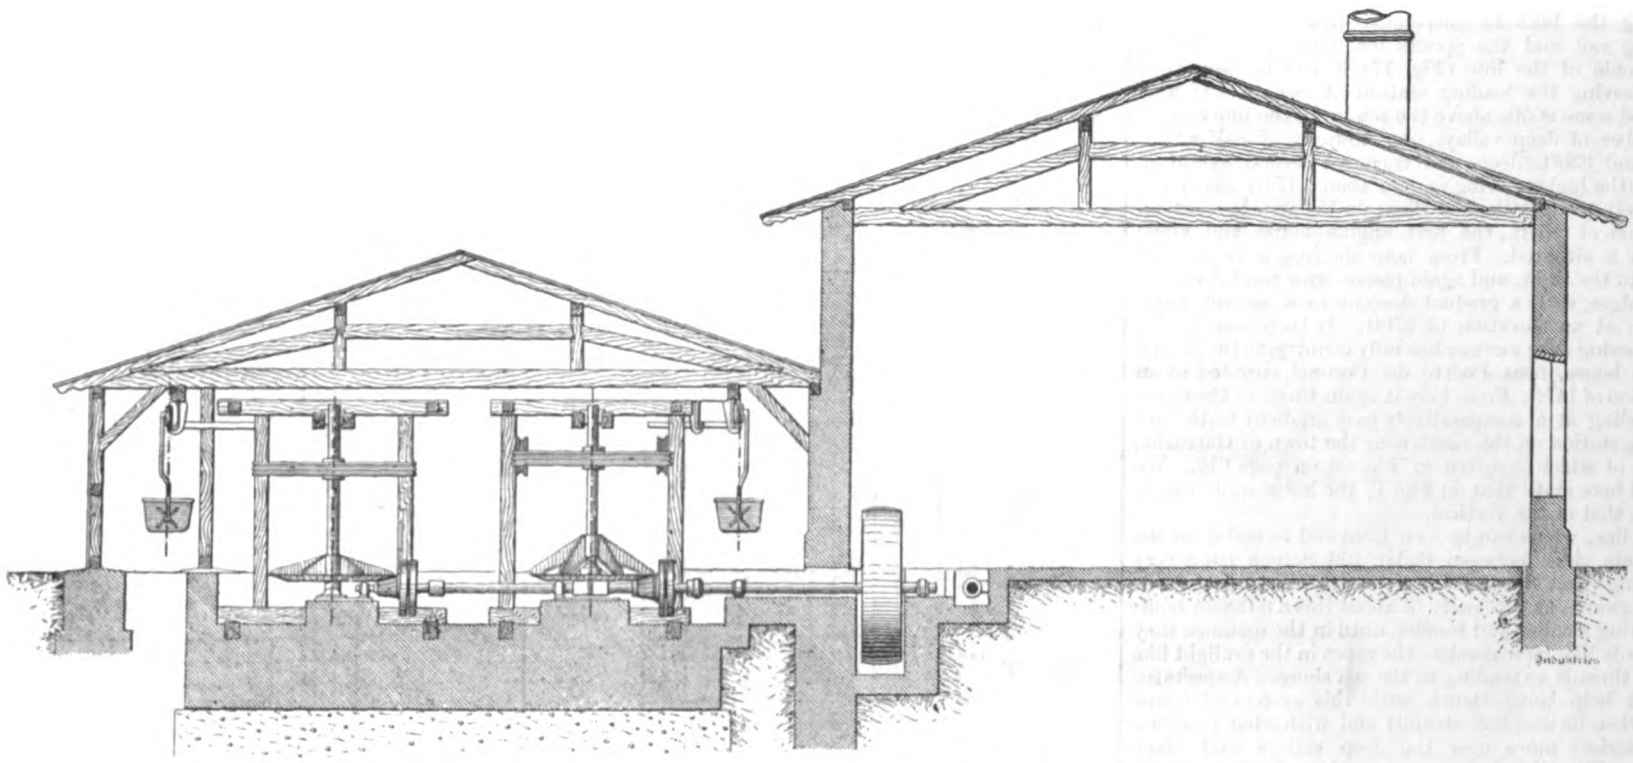

FIG. 16.—TRANSVERSE SECTION OF ANGLE STATION.

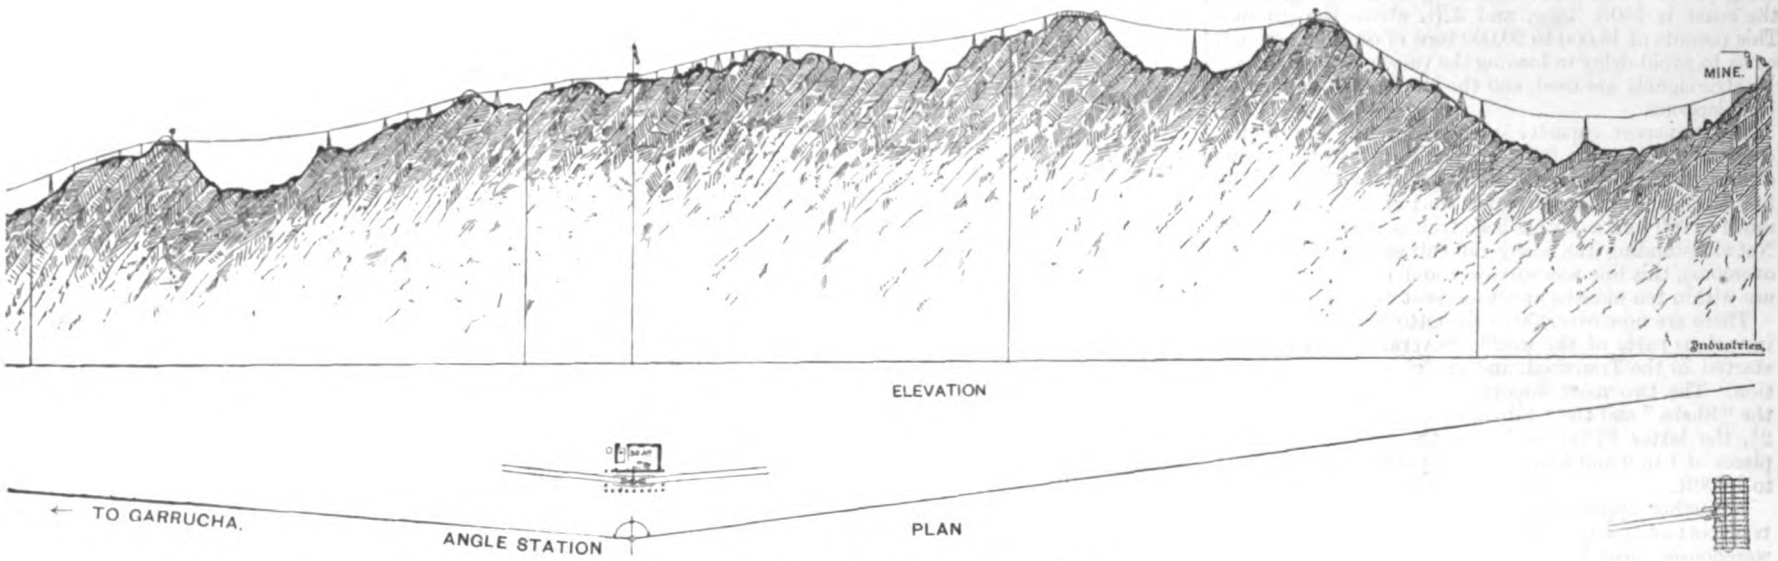

FIG. 17.—PROFILE AND PLAN OF PART OF LINE.

THE GARRUCHA AERIAL ROPEWAY.

(*Concluded from page 578.*)

As these lines cannot be worked round curves it is necessary, provided the ropeway cannot be carried in a straight line from end to end, to insert angle stations. Figs. 14, 15, and 16 represent a longitudinal section, a sectional plan, and a transverse section, of one of these angle stations at Puerto del Coronel, the chief power station of the line. When the buckets arriving from Bedar reach the shunt rail at the angle station they are automatically disengaged from the hauling rope as above described, switched on to the shunt rails, and run round by hand on to the carrying rope of the next section of the line, where they are again attached to the hauling rope and sent off in the direction of Garrucha. To avoid a violent impact of the knot and the coupling, the shunter gets a bell signal when a knot is approaching, and he pushes off the bucket at about the same rate as the hauling rope is travelling. If the line is not required to work at its full capacity the empty buckets can be docked at the stations, sidings being provided on to which the buckets are shunted out of the way.

This line is divided into four sections, a 30 horse-power engine driving the two steeper sections, a 70 horse-power the other sections. In Figs. 14 and 15 is also shown the method of taking up the slack of the hauling rope and keeping the same taut by means of balance weights. The carrying ropes are weighted at their ends in a similar manner.

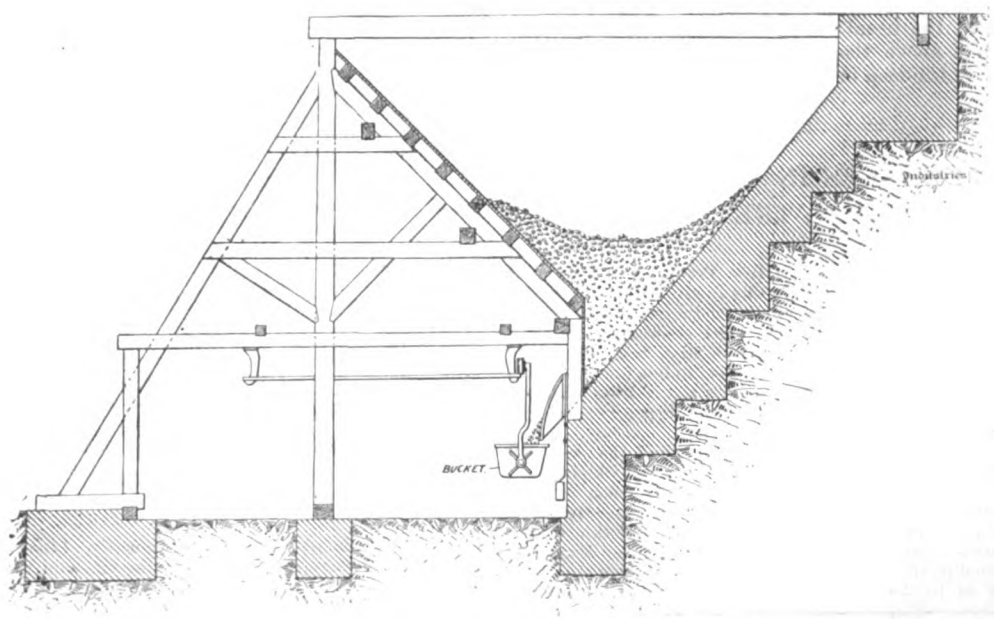

FIG. 18.—SECTION OF ORE BIN.

Digitized by Google

Fig. 19, on page 612, gives a view of the loading station. The trucks from the mine are run down a gravity incline to the ropeway station, and the contents tipped into bins or hoppers of a capacity of 800 tons. Fig. 18 gives a section of one of these bins, showing the buckets suspended from the shunt or hanging rail and the spouts for filling them. From the profile of the line (Fig. 17) it will be seen that after leaving the loading station at Serena, which is situated some 905ft. above the sea level, the line crosses a number of deep valleys, one upwards of half a mile wide and 330ft. deep, and traverses several mountain ridges (the highest being no less than 1,174ft. above the sea level), to the village of Pinar de Bedar, where, at an elevation of 951ft., the first engine house and angle station is situated. From here the line goes off at an angle to the right, and again passes over several valleys and ridges, with a gradual descent to a second angle station at an elevation of 370ft. It then bears to the left, passing over more or less hilly country, to the second engine house, near Puerto del Coronel, situated at an elevation of 147ft. From here it again turns to the right, descending at a comparatively easy gradient to the unloading station on the coast, near the town of Garrucha, a view of which is given in Fig. 20 on page 612. We should here state that in Fig. 17 the horizontal scale is double that of the vertical.

The line, which can be seen from end to end from the mountain ridge between Bedar and Serena, has a very imposing effect—the 660 buckets travelling backwards and forwards at a velocity of about three miles an hour, appearing smaller and smaller, until in the distance they look only like mere specks—the ropes in the sunlight like silver threads extending to the sea shore. A spectator cannot help being struck with this system of transport when he sees how steadily and with what precision the carriers move over the deep valleys and steep ridges. The other long spans vary from 328ft. to 750ft., the average distance of the supports from one another being about 130ft. The unloading station (Fig. 20) at the coast is 150ft. long, and 32ft. above the ground. This permits of 18,000 to 20,000 tons of ore being stored, so as to avoid delay in loading the vessels as they arrive. Electric signals are used, and the stations are connected by telephone.

The transport capacity specified for this line in the original contract was 600 tons per day of 10 hours, but of late, owing to the increased demand for this ore, the line has been working a double shift of 8 hours, and as much as 900 tons a day has been transported to the coast. Notwithstanding the many difficulties that had to be overcome, this line was surveyed and erected ready for use within ten months at a total cost of £26,000.

There are now over 450 of the Otto ropeways at work in various parts of the world. Several have lately been started in the Transvaal, and are giving every satisfaction. The two most important lines out there are at the "Sheba" and the "Edwin Bray" mines, the former 2¾, the latter 3¾ miles in length, with gradients in places of 1 in 2 and 1 in 1·6, and spans of from 1,400ft. to 1,600ft.

A further application for these aerial lines is in the transport of goods, boxes, barrels, sacks, &c., between warehouses, over buildings, railways, canals, &c., where an ordinary line could not be employed. The loading and unloading is very rapid and easy, and can go on in all states of the weather. No purchase of land is necessary for the permanent way, but only the lease of a strip about 10ft. wide is required, and this, with the exception of a small area at the points of support, can be cultivated in the usual way, the buckets travelling at such a height above the ground as not to interfere in any way with the men or cattle in the fields.

ON THE CHANGES IN IRON PRODUCED BY THERMAL TREATMENT.*

In a paper "On the Changes in Iron Produced by Thermal Treatment," † read last year before this Institue at the request of Professor Roberts-Austen, I published the results of some experiments made a few years ago, which showed that in addition to the three points of change which have been observed by Osmond, there appears in very mild steel to be a fourth point, which occurs at a temperature approaching the melting point of the metal itself; and I further showed that this point of change coincides with the point of maximum tenacity.

In the discussion which ensued on the reading of the paper it was observed by M. Osmond that the change which took place at this high temperature might have been due to the fusion of iron oxide adhering to the metal, the fused oxide being subsequently absorbed by the iron. Admitting the possibility of this, other experiments were made in a similar manner, but under strongly reducing conditions, and as the results seemed to show that the suggestion as to the effect being due to oxide could not be correct, the experiments have been continued. The results obtained are not without importance, as they have shown:—(1.) That in iron containing 0·1 of carbon, the tenacity of the metal increases by hardening either in oil or in water, with the temperature at which the metal is quenched with a view to hardening, a maximum tensile strength being reached at a temperature of about 1,300° C. This temperature once exceeded, however, the tenacity of the metal diminishes, although the extensibility increases. (2.) By raising the percentage of carbon from 0·1 to 0·2, the maximum tenacity is attained, not at 1,300° C., but at a much lower temperature—about 1,000°—below the melting point of iron oxide, which, moreover, was not present. (3.) By further considerably increasing the percentage of carbon, this point of maximum tenacity apparently disappears almost entirely, the annealed metal having nearly as high a tensile strength as the same metal which has been quenched in oil from any temperature up to a bright red heat. Beyond this temperature, or when quenched in water, the hardened metal became so hard and brittle that it could not be gripped by the jaws of the testing machine. Whilst, however, the tenacity of the high carbon steel was not greatly influenced by quenching, both the hardness and the brittleness of the steel increased with the initial temperature of the metal before quenching, until at the initial temperature of about 1,400° C., obtained by heating the metal in a crucible in a wind-furnace, the iron had become so brittle that there was very little resistance to shock at all, either when hot or after hardening. The metal, even if cooled gradually in a muffle from this temperature, was also extremely brittle. It should be observed that this temperature of 1,400° was that of the incipient fusion of the steel.

The tenacity of iron would appear not to be directly connected with its degree of either hardness or brittleness. Neither is this change in the mechanical properties of the metal at high temperatures due to a "carbon change," for it is most pronounced when carbon is almost absent, the introduction of increasing percentages of carbon apparently having the effect of producing a gradual diminution in the temperature at which the change takes place. The change is not due to oxide. Is it an "iron" change? Is it due to a form of iron existing when left to itself only at temperatures approaching the melting-point of the metal, but rendered stable at lower temperatures by hardening or by the presence of carbon? Very probably other elements besides carbon have a similar effect, but in these experiments an endeavour has been made to render the results comparable by using steels of approximately the same composition, with the exception of the carbon. The following are analyses of the milder steels used:—

Steel.	C.	Mn.	Si.	S.	P.
1.....	0·13	0·284	0.004	0·069	trace.
2.....	0·12	0·546	0·011	0·089	trace.
3.....	0·20	0·350	0·012	0·160	absent.

The curves of magnetic permeability of Nos. 1 and 2 were published in the original paper, but as these results might, to some extent, have been influenced by the presence of temporary internal strains resulting from the hardening, two other series of bars of the Bessemer metal were hardened in oil and in water, placed vertically in a glass jar, and allowed to remain for a year before submitting them to examination by the Hughes magnetic balance. The results are shown in Fig. 1, and are quite concordant with those previously exhibited, except that the hardened bars, under the influence of the earth's magnetism, had become more strongly magnetic, with the result that the curves representing their direct repellant action on the magnetic needle of the balance are much more regular, and the salient points more pronounced. The dotted lines represent the bars hardened in oil, the others showing those hardened in water. The tensile test-curve is shown at foot, and is that published last year for the other bars. There are probably unobserved maxima existing between the two higher points of the curves of magnetic permeability.

The other steels were examined in the same manner as that described in the previous paper, but using a reducing atmosphere. Fig. 2 gives the curves obtained with the steel containing 0·2 per cent. of carbon.

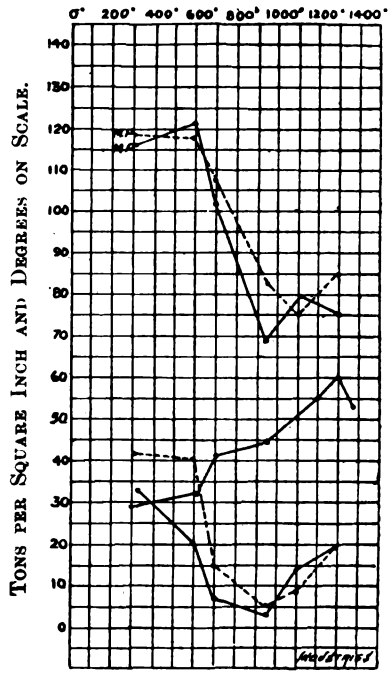

Fig. 1.—Temperatures.

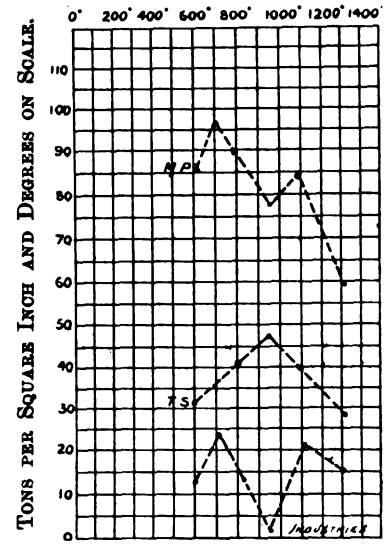

Fig. 2.—Temperatures.

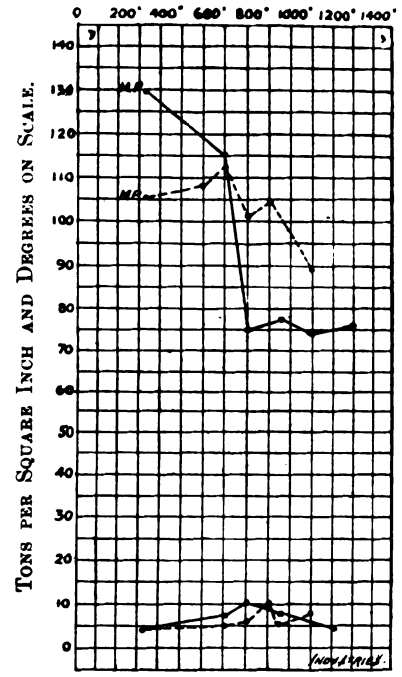

Fig. 3.—Temperatures.

These curves show (M.P.) the magnetic permeability of the bar hardened in oil, its tensile strength (T.S.), and its direct repellant action on the needle of the balance. This steel was in the form of a round rod 0·167in. in diameter. Hardened in water, the maximum strength was 65 tons, this strength being attained at the same temperature as in the case of the oil-hardened bars, and diminished again rapidly at higher temperatures. Fig. 3 gives similar results as obtained with the high carbon rod. This had a diameter of 0·231in.

I have endeavoured in these later experiments to meet the objection of M. Osmond that the change observed in very mild steel at about 1,300° is due to the formation and fusion of iron oxide. The experiments which are now described were conducted under conditions which prevented the formation of oxide, and while the bars, in the earlier experiments criticised by M. Osmond, showed scale, they were now free from it. Again, in the 0·2 steel, the maximum tensile strength was reached below the melting-point of the oxide, even had it been formed, which was not the case. M. Osmond further suggests that the change is closely connected with the structure of the metal. This seems not at all improbable. It does not appear, however, to be directly connected with a change in the mode of association of the carbon, as the carbon changes have taken place long before the maximum tenacity has been reached in mild steel. Neither does it appear to be due to the sudden development of crystallisation observed by Brinell, for if this were the case, instead of a gradual rise in the tensile strength to a maximum, followed by a gradual fall, accompanied, at least at first, by increased extensibility, a sudden and considerable diminution in the tenacity and extensibility might be expected. Whether this increased tensile strength is entirely or only partly a direct consequence of the strains produced in the metal by the act of quenching is again an open question, but it is evident that by quenching from a high temperature a change of some kind is produced in the iron under treatment, and that the extent of this change is dependent on the temperature and on the chemical composition of the metal.

In view of the abnormal results obtained on hardening the high carbon steel previously referred to, I hesitate to publish details, but prefer to reserve this question to a later date when I hope to be in a position to give the results of other and more complete experiments which are now in progress.

THE ROYAL NAVAL EXHIBITION.

MESSRS. G. E. BELLIS & CO.'S EXHIBITS.

The accompanying illustration (Fig. 1) refers to a set of compound centrifugal pumping machinery exhibited by Messrs. Bellis & Co., in the Camperdown Gallery. The exhibit represents one of the four sets that the firm are supplying for H.M.S. "Resolution" and "Revenge." The pumps, as fitted in each ship, are capable of lifting 2,200 tons of water per hour when running at 250 revolutions per minute, and though their primary duty is to supply the main condensers with circulating water, they are so constructed as to allow of their being utilised for pumping from the bilges in cases of emergency.

The engines, as shown by the illustration, are of the tandem type, a piston valve controlling the admission and emission ports of the high-pressure cylinder, while an ordinary flat valve is employed in conjunction with the low-pressure cylinder; these valves, mounted on the same spindle, being actuated by an ordinary eccentric. The high-pressure cylinders and valve chests lift off bodily by simply disconnecting and breaking the faced joints of each, thus admitting of easy and thorough examination of the high-pressure piston, cylinder, valve, &c.; and as the guides are cast in one with the bottom cover of the low-pressure cylinder, it is only necessary to remove one set of nuts to get at the interior of this cylinder and the bottom side of its piston. Ample provision is made for lubrication by means of the sight feed arrangements shown. Every part may be oiled round by hand in the usual way, or the small funnels fitted at the top of each pipe may be fed from the can should the drop-by-drop valves shown become choked.

Fig. 2 shows this firm's Navy-type compound single valve engine fitted to one of Latimer Clark, Muirhead, & Co.'s "Westminster" compound shunt-wound dynamos. In this engine a single valve, of the long piston type, placed between the two cylinders and driven by a single eccentric and rod, controls the steam and exhaust ports of both the high and low pressure cylinders, and is in turn controlled by the centrifugal governor bolted on to the crank cheek and adjustable to any designed point of cut-off before starting. As the single valve controls both cylinders, the cut-off in each is, of course, simultaneously coincident, and that the type of governor fitted is well adapted for its purpose is evidenced by the fact that one of these engines when tested for speed variation, only rose from 320 to 323 revolutions per minute, when its full load was suddenly thrown off. As in the previously described pumping engines, all parts are open and readily got at, the lower cylinder covers and guides are cast in one, and ample provision is made for lubrication, a sight-feed lubricator being fitted to each of the crank shaft bearings.

The engine and dynamo, shown in Fig. 2, when running at 320 revolutions per minute, give an output of 400 amperes at a pressure of 80 volts, and supply current simultaneously to two of the search lights in the grounds, each taking 100 amperes, and to upwards of 100 16 c.p. incandescent lamps in the Camperdown Gallery, and these latter are not perceptibly affected by the instant switching out of one or both of the "searchers." The makers have supplied similar sets to the one illustrated to Her Majesty's ships.

The firm also show on this stand a somewhat smaller set of direct-coupled compound engine and dynamo, which differs from the one just described in that the valves placed at the back of the cylinders are driven by a swinging link gear deriving its motion from the high-pressure connecting rod. Sets similar to this have been fitted on H.M.S. "Nile," "Royal Oak," and other ships. When tested, twelve hours daily for fourteen days, with full load on, to satisfy Admiralty requirements, it was found that one pint of oil sufficed for twelve hours' lubrication.

Messrs. Belliss also exhibit one of their triple air compressors, many of which have been supplied by them to the British and foreign navies. In the one now referred to the three cylinders and valve chests, cast all in one piece, are placed below the pumps and above the cranks, the whole being carried by four turned steel columns. One of these compressors was tested for three hours with full load on, and frequently gauged to ascertain if there was any defection of the pumps, but no defect was observable. Each cylinder and pump may be disconnected independently, thus allowing of No. 1 cylinder being used to drive No. 2, or 3, pump, and so on. When running at 350 revolutions per minute, and with a steam pressure of 100lb., a reservoir having a capacity of 10 cubic feet was charged up to 1,800lb. on the square inch in 19 minutes.

The double air compressor and air reservoir in the Armstrong Gallery were supplied by this firm, and are used daily in working the 6in. 5-ton hydro-pneumatic disappearing gun, for actuating the rammers shown near the 110-ton gun, and charging torpedoes in the Camperdown Gallery. In all types of their compressors Messrs. Belliss place the highest pressure pumps innermost, the two lower pressure pumps, and the cooling coils, being placed outermost, so as to confine any fragments of metal that would otherwise fly in the event of the highest pressure pump bursting. The double type of compressor stands on a base of 2ft. by 2ft. 9in., and the reservoirs on one of 2ft. 6in. by 6ft. 6in., and assuming the latter to be charged up to 1,800lb. on the square inch, their joint capacity is equal to the charging of one service (Whitehead) torpedo with air at 1,500lb. per square inch every four and a half minutes.

In a recent issue we described Messrs. Maudslay's and the General Engine and Boiler Company's exhibits, and stated that these two firms were the only exhibitors of air compressors. We regret that we overlooked Messrs. Bellis' compressing machinery in publishing our former notice, and are pleased to see that they make such a good show of this class of machinery

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 23rd June, 1891.

The Iron Market.—Business on the Paris market has been comparatively dull during the past week and there is a decided tendency to a fall in prices, but up to the present no general reduction has been made. The prices fixed by the Syndicate are the same as they have been for some time past—namely, 140s. 6d. for bars, 152s. 6d. for joists, and 168s. 6d. for No. 2 sheets per ton—but business is transacted at fully 5s. per ton under these quotations. There is a good market for old iron rails at from 83s. to 85s. per ton, and castings are in fair demand at 112s. 6d. A contract for the iron work for a landing stage at Pauillac, the port of Bordeaux, has been given to La Société des Etablissements Eiffel. As a consequence of the large orders that have been recently given for railway rolling stock there is just now a good deal of activity in the pneumatic brake constructors' shops, those of the Westinghouse Company at Paris being particularly busy. In the North prices, especially those of joists, are inclined to rise; bars are easily disposed of at from 120s. 6d. to 124s. 6d. per ton.

Copper.—The official quotations for copper during the past week were:—Best Chilian bars, £58 5s.; ordinary Chilian bars, £56 5*s.*; Chilian ore in cakes and ingots, £59 5s. 6d.; and best selected, £60 5s. per ton. It is rumoured that another syndicate is being formed to force up the price of copper bars to about £60 per ton, and hold them at this quotation. The moment seems to be a fairly propitious one for such an enterprise, as most of the stocks on hand have undergone a diminution since the failure of the French syndicate in 1889, and there has been a good demand for this metal for some months past.

The Flax Spinning Industry in France.—In 1850 there were 250,000 spindles; in 1860, 502,692; and in 1867, 705,350 spindles. Since then the number has been gradually decreasing. Thus, in 1875, the number of spindles had fallen to 686,000, in 1879 to 500,000, and at the present moment it is doubtful whether there are 400,000 at work.

Dyers' Strike at Lyons.—The employés of Messrs. Pierron & Bouchard, dyers at Villeurbanne, near Lyons, have gone out on strike by reason of a dispute with the foreman. If the strike is prolonged for three days the owners of seventeen other dyeworks in the neighbourhood threaten to close their establishments, the claims of the men being considered unjustifiable. This action on the part of the employers would throw about 2,000 workmen out of work.

Electric Tramways.—A tramway laid down by the Decauville Company a short time since on trial at Bourg has proved such a success that the municipality of this town has granted the director of the electric lighting department there a concession of thirty years for the working of the line. The cars, which were run for the first time last year on trial in the Champs-Elysées, at Paris, are lighted as well as propelled by electricity stored in accumulators. The track is of only 23½in. gauge, and curves of 16 yards in radius are practicable. It is said that these cars have no difficulty in running up grades of 1 in 80.

BERLIN, 22nd June, 1891.

The Iron Trade.—The iron trade in general, and especially the business in rails, is in an unfavourable condition. In the recent award of contracts invited by the Baden State Railways unsatisfactory prices were quoted. Messrs. Hope & Co. offered steel rails at £6 1s. 5d. per ton, the Bochum Union and Messrs. Krupp at £6 2s. 5d. per ton. Iron sleepers were offered by the Horder Union at £6 4s. 10d. per ton, by the Gutehoffnung Works at £6 4s. 11d. per ton, and by the Hösch Works, at £6 5s. 1d. per ton. The quotation made by a Belgian works was £6 12s. 2d., which was in excess of all the other offers. The Röhrig Rolling Mills in Brunswick are asking the Mid-German Rolling Mills Union to allow them to quote a lower price for a large quantity of work, as the work will otherwise be lost to them.

The Coal Trade.—At the last monthly meeting of the owners of Westphalian coal mines and coke ovens it was determined to raise the price of furnace coke for use in German steel works by 1s. per ton, and to fix the price for Coppée coke for export at 12s. 9d., and for furnace coke at 13s. 9d. per ton. Members of the union are to be allowed to export coke at the lowest price quoted for German firms. The Rhenish Westphalian coal market is steady, as is shown by numerous inquiries for coal for future delivery. The forwarding of coals in Southern Germany and on the Rhine has been interrupted by the recent unfavourable weather.

The Petroleum Industry.—The yearly report of the Harburg Chamber of Commerce contains the following interesting information with reference to the monopoly of the German petroleum trade. The business of Messrs. W. A. Riedemann, who possessed a store of petroleum, has been taken over by the German-American Petroleum Company. During the year 1890, 64,053 tons of refined petroleum were imported in nineteen shiploads, and 421,451 barrels of petroleum were despatched to Berlin, Breslau, and the chief towns on the Elbe. Two steam elevators were erected, and were capable of raising 6,000 empty barrels daily. The whole of the works are lighted by electricity, for which purpose a dynamo, driven by a 14 h.p. steam engine, produces a current of 167 amperes at 110 volts. Up to the present time 8 arc lamps and 81 incandescent lamps have been used. On January 1st the petroleum stores of Messrs. Sanders & Co. also became the property of the German-American Petroleum Company, so that the latter company now has the whole trade under its control. The Harburg petroleum business is already considerably greater than that of Hamburg. In the past year 686,452 barrels of petroleum were imported into Hamburg, and 811,513 barrels were imported into Harburg. The export from Hamburg amounted to 661,479 barrels, and from Harburg to 837,831 barrels. The action of the German-American Petroleum Company will, perhaps, increase the use of Russian oil. It may also account for the deep borings now being undertaken in Germany.

VIENNA, 22nd June, 1891.

The Iron Market.—The condition of the iron market has not shown any important change during the past week, and purchases do not exceed what is necessary to supply immediate wants. Prices of all sorts of iron, with the exception of rolled iron, have remained unchanged. Quotations for rolled iron show a firmer tendency, and iron and machine works are all fully employed. The Brünn Machine Works have just completed some large orders, and are now constructing two engines of 1,000 h.p. each, which have been ordered by the English syndicate of the Aussig Sugar Refineries. At a general meeting of the "Poldihütte" Crucible Works it was recently determined to increase the share capital from £75,000 to £140,625 by the issue of 3,500 new shares, in order to extend the works, and increase the manufacture of rolling stock.—Some large orders for iron have been placed by the authorities of Carlsbad for the purpose of repairing the damage caused by the floods.

The Coal Market.—The coal market continues to be extremely active, notwithstanding the advanced season. The export trade is especially brisk, and this fact has had a favourable effect on the prices of coal mine shares. During the past few weeks the prices of coal mine shares have shown an important rise, which, in the case of the Salgó-Tarján Company, has amounted to nearly 40 per cent., whilst the shares of most of the other coal mines have risen from 20 to 30 per cent.

Electrical Engineering.—The management of the Budapest City Railway has been seeking permission for some time past to supply electrical power to private persons for industrial purposes. The chief city engineer is of opinion that the supply of electrical power would be very advantageous in the carrying on of small industries. He states, moreover, that the electrical central station of the City Railway Company, formerly belonging to Messrs. Siemens & Halske, is quite sufficient for the working of the railway and for supplying power to private works. This would be the case even if the railway were to be further developed, since the central station can be enlarged. The cable system is now being enlarged, and the distribution of power will shortly be set in operation. The Budapest City Railway will soon receive an extension, as some lines which run to the suburbs and to places of pleasure resort, about 4½ miles beyond the town, are to be amalgamated with the city line.—The Carlsbad Board of Works is actively engaged in considering the project of an electrical tramway, which would be of great service to the numerous visitors at that health resort.

The Free Harbours of Trieste and Fiume.—On the 1st of July next the tolls of the "free harbours" of Trieste and Fiume are to be abolished, and free traffic between these districts and the other parts of the kingdom will commence on August 1st. The sole remaining imposition of tolls in the kingdom will thus disappear. The inhabitants of these two towns have some difficulty in reconciling themselves to the new state of affairs, and the parliamentary representatives of Trieste and a deputation from that city have petitioned the Government for a postponement of the new regulation. They allege that the warehouses, which are rendered necessary by the freeing of the harbours, are not yet completed, and that some of the more important machinery is still wanting. The Marquis von Bacqueherst, the Minister of Trade, has, however, refused to grant the application, and the new law with regard to Trieste will come into force on July 1st. It seems probable, therefore, that Fiume, which has petitioned the Hungarian Government for a postponement of one year, will also fail to obtain its request.

BRUSSELS, 23rd June, 1891.

The Iron Market.—In the iron market the high price of fuel, and especially of coke, has seriously affected business. Little business has been done, with the exception of small sales at reduced prices. Some contracts for railway sidings have been awarded to Messrs. Noulet & Co., and contracts for railway crossings to the Société de l'Est de Marchienne. There is a good business in iron sheets, and the demand for both angles and joists is brisk. At Charleroi prices generally seem to follow the price of pig iron, which shows a firmer tendency, but at Liége the bad news in reference to the English market has seriously affected the demand. Red short iron is quoted at £1 18s. 5d., and Luxembourg iron at £1 18s. It is reported that an Italian firm has made a contract with some Belgian works for the construction of an industrial railway of about fifty miles in length.

The Coal Market.—The market continues firm, notwithstanding the arrival of foreign coal, and stocks are very low. After the award of contracts by the Belgian Government on the 17th inst. an attempt was made to raise prices, but without success. The price of coke continues high, and new ovens are likely to be started owing to the ready sale. Coke is quoted at 14s. 9d. to 15s.; coal nuts from £1 0s. 9d. to £1 1s. 7d., with a tendency to rise; small close-burning coal at 7s. 2d.; small steam coal at 9s. 7d.; coal nuts for furnaces at 11s. 2d.; household coals at 15s.; screened at 17s. 7d.

Electric Lighting in Belgium—Some statistics have just been published by M. Wybauw which show the actual state of electric lighting in Belgium. At Brussels 1,200 incandescent lamps are supplied by the station of the Tudor Company, 600 lamps supplied by the Montagne station at the Herbes Portagères, the installation of M. Vlierboom, 800 lamps in the Rue des Bouchers, 200 lamps in the Rue du Coude, and 600 lamps in the Place des Nations and the Rue Zérézo. At Ghent 1,000 lamps are supplied by the Station du Marais, and at Charleroi 1,500 lamps are supplied by the central station of M. Dulait. Altogether there are at Brussels 9,600 incandescent lamps and 545 arc lamps, at Antwerp 1,480 incandescent lamps and 240 arc lamps, at Ghent 4,930 incandescent lamps and 220 arc lamps, at Liége 2,010 incandescent lamps and 384 arc lamps, and at Verviers 2,430 incandescent lamps and 665 arc lamps.

Belgian Commercial Society.—This society was started a long time ago for the purpose of encouraging trade between Belgium and distant countries. Of Belgium exports, 80 per cent. are sent to the four countries which are close to Belgium, 10 per cent. to other countries of Europe, 5 per cent. to North and South America, and only 5 per cent. to the rest of the globe. There are very few Belgian firms which are concerned entirely in the export trade. The new society, which has been started with a capital of £40,000, will carry out its objects by buying and selling directly, or by the establishment of agencies. It will seek information as to the undertaking of new works, such as railway, gas, and water works. It will make inquiries as to the most advantageous conditions for sale, and will try to establish relations between producer and consumer. It may possibly happen that the action of the society will be disadvantageous to certain industries, but a circular is to be issued by the Bourse des Métaux asking Belgian manufacturers to subscribe the capital of the new society.

DÜSSELDORF, 23rd June, 1891.

The Iron and Steel Market.—The condition of the market is generally quiet. The price of pig iron shows a weaker tendency. An important event of the past week was the placing of contracts for rails to the amount of 3,505 tons by the Royal Railway management. Two contracts for 755 tons and for 420 tons were offered by the "Königs und Laurahütte," and by the Upper Silesian Railway Supply Company at £6 4s. 4d. per ton. The remainder was tendered by the Georgs-Marien Works of Osnabrück at £5 19s. 6d. per ton delivered at Osnabrück. These offers were made by Messrs. Pintscher, of Altona, on behalf of an English works, the whole quantity being offered at £6 4s. 4d. delivered at Breslau. The other offers, inclusive of freight, were at £6 11s. 3d. to £6 11s. 9d., delivered at Breslau. Messrs. Pintscher have not disclosed the name of the English works, and it seems doubtful whether the contract will be awarded to them, notwithstanding that they quote a cheaper price, as German railways only obtain their rails from firms of some standing. Foundry and machine works are generally well employed, especially those which are engaged in the manufacture of large mining plant.

The Coal Market.—The despatch of coal from the Ruhr district is more active than it has been during the past season or in former years; 11,000 double waggons of 10 tons each are being despatched daily, and a deficiency of railway waggons is again being felt. On the 19th inst. there was a demand for 11,242 waggons, whilst only 10,775 waggons were forthcoming. Consumers feel some apprehension as to the supply of coal in the autumn, as there is always an increased demand for waggons on the part of farmers and sugar works during that season. It is feared that many industries will suffer inconvenience on this account.

Union of Gas and Water Engineers.—At a general meeting of this Union held at Strasburg during the past week the condition of the German coal districts came under discussion. Mr. Grassmann, assessor of mines, estimated that there were 565 million cubic metres of coal in the Saarbrück region, which would amount to 14 milliards of tons of coal. The present yearly output amounts to 6 million tons, so that the supply will last for 2,339 years. Dr. Brookmann spoke of the Ruhr district, in which 130,000 workmen are employed, with a yearly output of 630 million tons; 165 mines are now in operation in that district, of which 25 produce gas coal, 70 bituminous coal, and 70 poorer sorts of coal.

An English Cotton Mill in Germany.—An English company has been formed at Gladbach, Rhenish Prussia, under the title of the Rhenish Cotton Spinning Mills, Limited. The capital of the company is £80,000, and its head office is in London.

Digitized by Google

AMSTERDAM, 22nd June, 1891.

Steamship Companies.—The report of the Board of Directors to the shareholders of the Zeeland Steam Navigation Company in Flushing for the year 1890 is not of such a favourable nature as they could wish. The gross receipts have increased from £118,819 to £121,209, but the working expenses also have from £91,305 to £98,333, chiefly in consequence of the higher price of fuel. The net receipts fell from £27,522 to £22,877. Deducting debenture interest and other payments, there only remains a balance of £8,679, which has been placed to the credit of the depreciation account. The steamers of the company in 1890 performed 730 journeys, half of which were in the day service, carrying 76,333 passengers, against 74,198 in 1889; and 44,698 tons of goods, against 44,698 the year before. The company received £25,000 on account of the carriage of letters, and £200 on account of the carriage of parcels. 1,231 tons of postal matter were carried.

State Railways.—The report for 1890, presented by the Board of Directors to the shareholders, is one of the most important in the history of the company which works these railways. The convention between the Government and the company underwent an important modification and extension by the purchase of the Dutch-Rhenish Railway system, the Leyden-Woerden Railway, and the steam tramway from Ede to Wageningen by the State, and their transfer to the State Railways Company. The system worked by the latter was thereby increased by 158 miles of railway and 7½ miles of tramway. The company also acquired the Central Railway shares, which were in the possession of the Dutch-Rhenish Railway. Deducting the mileage of railroads which were transferred to the Holland Railway Company, the system of the State Railways now comprises 986 miles of railway and 7¼ miles of tramway. The total receipts in 1890 were £1,242,354, the working expenses amounting to 52·74 per cent. Deducting various charges, there remains an available balance of £92,338, out of which the State Railways Company is entitled to a sum of £67,698, enabling the Board of Directors to distribute a dividend of 5¾ per cent. on the share capital of £1,083,300. This, in 1890, was increased to £1,500,000, whilst the shareholders authorised the issue of £500,000 in debentures.

Telegraphs.—The Minister of the Colonies has granted a concession to the Eastern Extension, Australasia, and China Telegraph Company, Ld., for laying down a telegraph cable from Labœan-Deli, on the East Coast of Sumatra, to Penang, which cable must be open for traffic in June, 1891, in such a manner that a through communication be established with the Government cables at Labœan-Deli, Batavia, and Banjœwangi. The company further agrees to pay the Government a certain royalty on all messages transmitted over the Government cables.

STOCKHOLM, 20th June, 1891.

The Gellivora-Lulea Railway.—The purchase by the Swedish Government of the Swedish section of the Swedish-Norwegian Railway having been finally completed, Swedish officials have recently visited parts of the line in order to inspect it before finally taking it over.

Workmen's Share in Profits.—The new Atlas Engineering Company in Stockholm has decided to give its workmen a share of the company's profits. For the present year 20 per cent. of the profits is to be distributed amongst the company's men and officials. The following conditions must be complied with:—The men must have served for at least one year, they must have borne a good character, and must have completed their twenty-first year. One-third is paid at once, and the remaining two-thirds go to a fund for payment after twenty-five years' service, or when the fifty-fifth year of age is completed.

The Motala Engineering Company.—This company has for several years past been in a very unsatisfactory state, in spite of no apparent lack of orders, and notwithstanding the assistance rendered in various ways by the Swedish Government by means of large contracts and loans. Things have now come to such a pass that, unless a reconstruction of the company be arranged, a catastrophe seems impending. At a meeting in Stockholm a few days ago a plan was discussed which would involve a further Government loan of £33,330, in accordance with which a number of creditors would take shares in the new company in lieu of their claims. The old share capital would have to be considered as lost. No definite decision was arrived at, but another meeting is to be held shortly in order to settle the matter.

CHRISTIANIA, 20th June, 1891.

New Railways.—The latest proposals of the Government in respect to new railways, which embrace the North Railway, the Eidanger-Brevik Railway, and the Bergen Railway, have been referred to a committee. Of these the first and the last are most important lines. The Government is against the partial combination of the North with the Bergen Railway, which is not thought likely to prove satisfactory. The two most likely routes for the North Railway are through Christiania, Haklon, and Gjövik, and through Grorud, Hakedal, and Gjövik, the calculated cost being respectively £577,550, of which £75,000 would be spent on the extension of Christiania Railway Station, and £454,776. From a financial point of view the authorities see no objection to the construction, with Government aid, of a railway to Gjövik at a calculated cost of £583,300, of which 20 per cent. is expected to be forthcoming from local grants. The Government, in consequence, proposes the building of a Christiania-Gjövik Line, at a cost of about £583,300, along the following route:—Christiania, Maridalen, Grun, Tingelstad, and Gjövik. The Bergen Railway is calculated to cost about £1,944,000. The Department is in favour of an inland line, as being preferable from both a national and a military point of view. With regard to the southern portion of this line, the Humledale line of route is recommended.

COPENHAGEN, 20th June, 1891.

The Danish Sugar Manufactories.—The large Danish Sugar Manufactories, which have works in different parts of the country, have had a surplus on last year's working of £66,215, which, with a balance carried over from last year, makes a total of £69,531. From this amount £13,885 is deducted for interest, and £1,930 for salaries, leaving an available sum of £53,726. Of this the shareholders get in the first instance 5 per cent., or £25,819; 15 per cent. of the balance is added to the reserve and renewal fund, amounting to £3,670. The board get in tontine £491, and the managers £1,229, the company's servants and men £737, and the ten-yearly beet growers £1,864. Further, £13,888 are added to the reserve and renewal fund, and the shareholders get an additional 1 per cent., or £5,163.

The Copenhagen Free Harbour.—The works on the new free harbour at Copenhagen have now been commenced in earnest. A great deal of pile-driving is going on, for the purpose of partitioning off a large area, which will afterwards be pumped dry, and then excavated to the proper depth. This will do away with the small harbours for boats in that locality, but accommodation will in the meantime be provided for these somewhat nearer the town.

MADRID, 22nd June, 1891.

The Madrid Gas Company.—English gas engineers may find a difficulty in understanding how a gas company which sells gas at 9s. per thousand feet, and coke at 45s. per ton, is unable to offer its shareholders a larger dividend than 3¼ per cent. There is no place, perhaps, where gas lighting is more used than in Madrid. The explanation of this anomaly is that the Madrid Gas Company pays in interest to its debenture holders eight times as large a sum as it is required to invest in the undertaking. The results for the present year are likely to be even more unfavourable than those of the year 1890, as many persons now prefer to use the electric light instead of gas, even at the high price of 1s. 3d. per unit.

The Port of Bilbao.—Considerable progress has been made with the large works which are being carried out at the mouth of the Nervion, and which will make the port suitable for all sizes of vessels in any state of the weather. The works will not be completed before five or six years, but access to the port will be facilitated within a shorter period. Much advantage is expected to arise from the execution of the works in the outer port, in view of the fact that an iron industry may be established at Santander. It is perhaps rather difficult to see how this advantage will be gained, as vessels of more than 3,000 tons can even now enter the port of Bilbao.

Daimiel and Talavera Railway.—The Senate has passed a law, according to which the Government may grant a concession for a railway from Daimiel to Talavera. The line could be easily constructed, but the traffic would be very small. The object of making the line is probably to secure a good position for the coming railway war in Spain. The northern system of railways will try to connect its lines with the south of Spain and the port of Valencia, and the proposed line would form a part of this extension. Unless the two large companies enter into some arrangement many lines of the same character as the proposed line will be constructed by the one company in order to show its capability of injuring the traffic of the other.

ROME, 22nd June, 1891.

Italian Lignites.—In their natural condition these lignites contain from 17 to 40 per cent. of moisture, and after having been dried in the open air they still have from 10 to 25 per cent. of moisture; they have from 5 to 15 per cent. of ashes, and often contain over 5 per cent. of sulphur. The method of utilising the lignite proposed by Mr. Sapori consists in a dry distillation of the lignite in retorts similar to those used for the production of gas. A part of the gas produced is used for heating the retorts, and producing coke in addition to the tar (brai) and ammoniacal liquors. The gas thus produced gives, it is stated, a heating power of 8,000 calories, and the coke remaining in the retorts has a heating power of 7,000 calories. From the distillation of 1,243lb. of "lignite xiloide" in four hours, Mr. Sapori had a return of 31·15 per cent. of gas, and 33·38 per cent. of coke. The gas, notwithstanding its incomplete purification, gave a light equal to that of gas produced from coal. The lignite gas was found to have a heating power which was capable of getting up steam in the boiler of a locomotive containing 700 litres of water in forty-five minutes. It is able to melt glass, bronze, pig iron, and iron ingots, in a short space of time. The coke obtained from the distillation had no smell, and was suitable for industrial and household purposes. Mr. Sapori completed his experiments by manufacturing briquettes with the lignite coke, mixed with tar obtained from the distillation of the same lignite. The Mediterranean Railway Company has made several experiments with this special fuel, the last being the one recently made on the line from Rome to Frascati. In consequence of these experiments many manufacturers have come to the conclusion that it will be no longer necessary to import fuel and other products from abroad. It is, however, necessary to look carefully into the matter both from a scientific and from a practical point of view, in order to ascertain how much truth there is in this statement. From investigations made by the Royal Commission of Mines, it appears that the lignite coal mines which have been found in Italy up to the present time could not give a regular output of more than 700,000 tons at the utmost. From a geological study of the districts where other workable lignite coal mines are usually found, it appears that the total annual production could never reach 1,000,000 tons under the most favourable hypothesis. In Italy there is an annual consumption of 5,000,000 tons of fuel, so that even if the lignite had an equal heating power to the good qualities of the coal now imported from abroad, it would be able to supply only one-fifth part of the requirements of Italian industries.

NEW YORK, 13th June, 1891.

The Hudson River Bridge.—The New York and New Jersey Bridge Company held its annual meeting on the 2nd inst. The report of the Executive Committee states that the charters of both States have been confirmed by special Acts of Congress. The two North River Bridge Companies propose to amalgamate and to begin work on both sides of the Hudson simultaneously early in September. Propositions have been made by several large iron manufacturers who are prepared to sign a contract to complete the entire work within thirty months of the time of beginning. The construction of this bridge will enable all the trains from Philadelphia and, therefore, from the South and West also, to run directly into New York City. Much time has hitherto been lost in crossing the Hudson River from Jersey City to New York in ferry boats.

Rapid Transit for New York City.—The Commissioners appointed to devise some plan to meet the pressing need for improved rapid transit have recommended the construction of an underground railway along Broadway. It would take several years to construct this railway. The cost is estimated at £8,000,000, on which the interest at 4 per cent. would be £320,000 a year, which would have to be earned in addition to the working expenses. This would require a yearly traffic of 23,000,000 persons. The four elevated railway lines carry 600,000,000 passengers a year.

New 12in. Steel Gun.—The first 12in. steel gun made in the United States has been completed at the Watervliet Arsenal, Troy, N.Y., and shipped to the Sandy Hook proving ground for testing. The gun weighs 52 tons. It is 36·66ft. long, and the length of its bore is 34ft. Its charge is 440lb. of powder, and its projectile weighs 1,000lb. The powder pressure which will be exerted on its interior when the gun is fired is 16·5 tons to the square inch. The initial velocity of the projectile will be 1,940ft. per second, the muzzle energy 26,000 foot tons. The tube and jacket forgings for this gun were purchased at Le Creusot, France, and the remaining forgings were obtained from the Midvale (Pa.) Steel Works. This is the largest steel gun built in this country, and the test, which will shortly take place, is being looked forward to with great interest.

PHILADELPHIA, 12th June, 1891.

A Large Casting.—Probably the largest casting ever transported by the Pennsylvania Railroad Company arrived at Johnstown on the 23rd ult., and was consigned to the Cambria Iron Company. It was a half-section of a fly-wheel, and weighed 90,000lb. The special car in which it was transported from Philadelphia was borrowed by the Pennsylvania Railroad Company for that purpose from the Baldwin Locomotive Works, the company having no car with a capacity above 80,000lb. The wheel is in halves for bolting together, and when complete is 25ft. in diameter, with a rim 18in. thick and 28in. wide. It is for the new 26in. billet mill now being erected by the Cambria Iron Company. The engine which will drive this wheel is a compound condensing one of 3,000 h.p., and is being built by the Southwark Foundry and Machine Company, of Philadelphia, which firm also made the fly-wheel.

Telegraphic Cable to Hawaii.—The Secretary of the Navy has selected the "Thetis" to be the vessel used in making a preliminary survey of the proposed telegraphic cable from San Francisco to Honolulu, and the work will probably be begun about July 1st. It has been decided to use the system of sounding devised by the hydrographer of the Navy Department, which consists in taking soundings at alternate intervals of two and ten miles, unless indications of shoals are found, in which case the soundings will be taken at one-quarter mile intervals until the exact character of the shoal is determined.

The Haskell Gun.—The contract for making the steel forgings for the Haskell multi-charge gun has been awarded to the Bethlehem Iron Company, and the contract for finishing the gun to the Reading Iron Company. The total sum appropriated for this purpose is £11,000.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

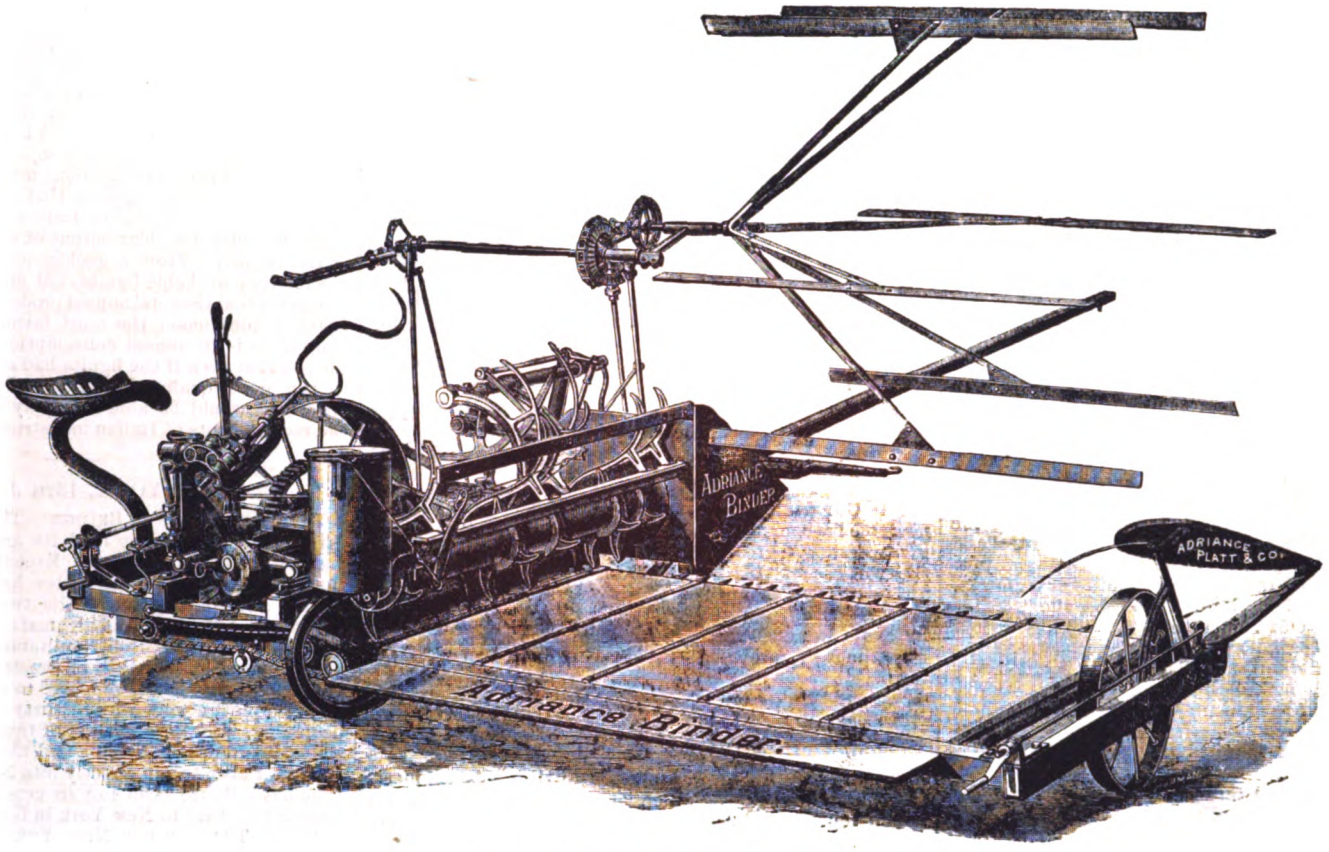

FIG. 1.—THE "ADRIANCE" BINDER.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT DONCASTER.

THE fifty-second annual country meeting of the Royal Agricultural Show was opened to the public on the 20th inst. Last year the show was held amidst picturesque scenery; this year, although the scenery is lacking, the show is a decided success. The number of implements exhibited is larger than in any year since 1884, with the exception of 1889, when the show was held at Windsor. The amount of space allotted to implements is 12,743ft., exclusive of open ground space, as compared with 9,078ft. at Plymouth last year, 15,602ft. at Windsor in 1889, 10,743ft. at Nottingham in 1888, and 8,217ft. at Newcastle in 1887. The site of the present show covers from 80 to 90 acres.

All the larger makers of implements are of course to be found strongly represented, but with their standard types, they apparently being satisfied to continue the manufacture of well-established machines. But several smaller makers show what they call "new implements," these being mostly improvements in detail of a well-marked type or the adaptation of an existing type to new work. Of absolute novelties we only saw two, one being the "Darby Digger," and the other, the compressed air sheep shearer exhibited by the Australian Shearer Company, Limited, of 81, York Street, Sydney, N.S.W., the English agents being Messrs. R. Hornsby & Sons, Limited, Grantham. Three of these shearers were exhibited, and practical demonstrations of the manner and the speed with which they operate were given during the show. At one of these we witnessed a sheep sheared in eight minutes, but the inventor states that five minutes per sheep can be easily managed. The implement in question is worked by compressed air instead of belting or gearing as is usual in power-worked sheep shearing machines. The dimensions over all of the shearer do not exceed 10in. by 3in. by 2in., and it can be easily held in the hand. The machine consists of a reciprocating double-pistoned engine, having a suitable air valve which controls its action, the piston working a lever pivoted in the centre of the machine at one end and the other end working the cutter, which is made with several teeth. The speed of the cutter is stated to be 3,000 strokes per minute. The invention is of Australian origin, but the machines are being manufactured in this country by Mr. C. G. Bonehill, Belmont Gunworks, Birmingham. The air pressure employed to work the machine is 25lb. per square inch; the compressed air is obtained in the usual manner by a steam engine and compressed air pump forcing the air into a wrought-iron reservoir, from whence it is led by overhead pipes to the shearing room. A flexible indiarubber pipe is attached to the main feed pipe at distances suitable for each shearer, and to the independent flexible pipe is fixed the new shearer, a small stop valve being interposed between the machine and the main pipe.

The "Darby Digger," shown by Messrs. T. C. Darby & J. E. Steevenson, Chelmsford, is a steam digger and cultivator of 10 h.p. It is the result of continued experiment and simplification of the Darby digger, exhibited some four years ago at the Smithfield Show. In the present machine hydraulic power has been introduced for steering and for putting pressure on the digging prongs. The leading feature of the machine is that the piston rods are coupled up directly to the digger crank shaft, gearing and fly-wheel being dispensed with. To regulate the fineness of the ground dug, fixed coulters are placed immediately behind the digging forks, and where the land is clean enough the seed may be drilled at the same time by means of a drill attached to the rear of the machine. To increase the bearing surface of the machine when passing over soft ground, rollers are bolted to the hind wheels to increase their width. The total weight of the machine is eight tons.

Messrs. J. & H. Keyworth & Co., Liverpool, show several American harvesters and binders, amongst which we noticed the "Adriance" binder, illustrated in Fig. 1. This machine has been tested for a few years on American work, and is now being introduced into this country. The features aimed at are lightness, with strength, simplicity, and elegance, and the balancing of all moving parts. The peculiar and limited elevation of the grain and the rear discharge of the bundle are novel. The action of the machine is as follows:—The grain, when cut, is reeled on to a moving canvas apron and carried to the lifting mechanism in the usual way. The grain is then conveyed to a series of revolving sprockets and a revolving butter disc located in the rear of the inner divider; by them it is carried upwards through a throatway on to curved ways or feeder scrolls, which serve to support the grain and also to clear the sprockets and prevent any winding of grain. Above the sprockets the feeder scrolls and the upper compressor form the grain receptacle, in which the grain remains until enough for a bundle has accumulated. The highest elevation of the grain is only 15in. The bundle is made when sufficient grain accumulates in the receptacle to raise the trip or bundle sizer; this puts the binder mechanism in motion, and the needle, which is in position above the receptacle, descends, enclosing the grain within the cord, and, at the same time, moves toward the binder deck which is on the opposite side of the feeder throat from the grain receptacle. The needle does not require to be forced through a mass of packed grain, but one of the sloped sprockets is timed to act with the needle and leave a clear way for the point. This sprocket carries the bundle to the binding deck, where it is compressed by a side compressor, which relieves the needle from strain. The tie is made at a time when both the needle and the discharge fork are relieved from work and returning to position, and while another bundle is gathering in the receptacle. The return of the needle to its first position is not, as in other binders, over the track of downward movement, but over a different course. Every motion of the needle and swinging binding arm is controlled by one crank. The discharge fork, pivoted at the rear corner of the binder frame, acts at the moment when the needle has enclosed grain for a new bundle, and lifts the bound bundle from the deck, turns it completely over endwise, and discharges it gently on the butts in the rear of the machine, but entirely out of the way of the next round.

Messrs. Ransomes, Sims, & Jefferies, Ipswich, have a large collection of exhibits, amongst which is one of their 6 h.p. traction engines, with wrought-iron driving wheels, and with compensating motion on the driving shaft; a 6 h.p. and an 8 h.p. portable engine of the same type, each having steam-jacketed cylinders. The wrought-iron brackets which carry the crank shaft are firmly riveted to the boiler, and the bearings of the crank shaft have both vertical and lateral adjustments for taking up the wear. The governor is connected to a double-beat piston valve. The boiler is large for the size of engine, and large wearing surfaces are given to all bearings. In addition, this firm shows a 10 h.p. compound under-type engine, with the cylinders steam jacketed; a 20 h.p. long-stroke stationary expansion engine; a vertical engine, with boiler combined, of 5 h.p.; and two 54in. steam thrashing machines. Ploughs, rakes, and haymakers also form an important feature in Messrs. Ransomes' exhibits.

Messrs. John Fowler & Co., Leeds, exhibit a fine collection of their heavy engines and ploughs, comprising a 6 h.p. nominal traction engine, an 8 h.p. ditto; a 12 h.p. compound ploughing engine, fitted with winding drum and coiling gear for the double-engine system of steam cultivation; a five-furrow balance plough, with anti-balance gear, which prevents the implement from jumping out of its work at whatever depth it is ploughing; a 12in. single-cylinder horizontal engine, fitted with Hartnell's patent automatic expansion gear. The "Oliver" plough is a magnificent specimen of agricultural machinery. This plough is specially made for deep work, and is largely used in the vine districts of France and

Digitized by Google

Spain, where deep ploughing for planting vines and trees is required. This plough is constructed of exceptional strength in all parts, and is capable of cutting a furrow 24in. wide and 30in. deep. A second plough of smaller size is placed in front of the large plough to divide the work. An 8 h.p. compound semi-portable engine is employed in driving Messrs. Bradley & Craven's brick machinery. A 10-ton steam road-roller, and an assortment of Messrs. Fowler & Co.'s light railway plant are also on view at their stand.

The Weardale Iron and Coal Company, Limited, Durham, have a very fine display of their manufactures. In addition to the samples of the various sizes and sections of iron and steel made by this company, specimens of the materials after being worked are to be seen.

Petroleum and gas engines are represented by a number of different makers. Messrs. Crossley Brothers, Limited, Manchester, have a good show, including a 14 h.p. "Otto" horizontal, capable of indicating up to 33 h.p. This engine is fitted with all the latest improvements, including Crossley's new patent tube and patent lining valve, and also a patent self-starter. A 4 h.p. gas engine is shown working with common petroleum oil, and is stated to be capable of indicating up to 9½ h.p. The oil used in this engine has a flashing point of 110°, and is supplied by the American Oil Company; the consumption is 0·8 pint per brake horse-power per hour. Messrs. Weyman & Co., Limited, Guildford, show their "Trusty" gas engine, a description of which was given in *Industries*, Vol. IX., page 568. Messrs. Wells Bros., Sandiacre, show the "Premier" gas engine, with a special drop governor in two sizes.

Messrs. Priestman Bros., Hull, exhibit four of their oil engines, ranging from 2 h.p. up to 18 h.p. Mr. John Robson, Shipley, Yorkshire, shows two sizes of his gas engines—a 4 h.p. and a 1 h.p. The engine rests on its own bed, and therefore requires no special foundation; the working parts are few, and the bushes are of phosphor-bronze.

Messrs. Page & Co., Bedford, show a variety of implements, including ploughs, scufflers, harrows, drills, and mills. Amongst the latter we illustrate one, Fig. 2,

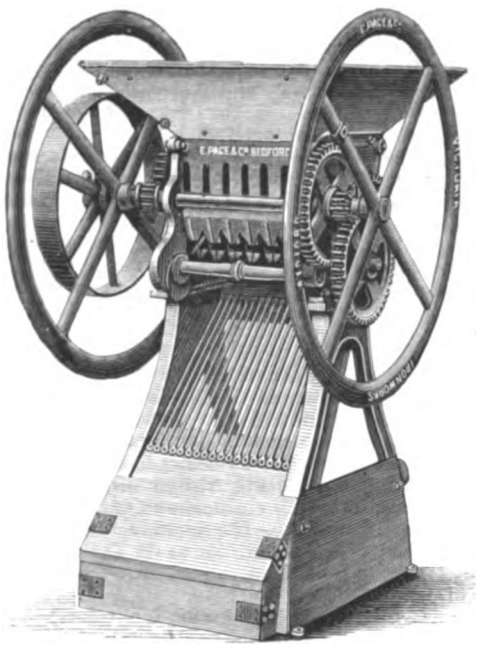

Fig. 2.

adapted to the breaking of coke for smiths' fires, greenhouses, and domestic purposes. This coke breaker is fitted with two pairs of rollers. Two men, by manual power, can break a ton of gas coke in about half an hour. A screen, fitted to the machine, enables the broken coke to be sifted from the dust, and the rollers are capable of adjustment so as to break four different sizes.

(To be continued.)

SHIPBUILDING NOTES.

The New South Wales Government have ordered from Messrs. Wm. Simons & Co., Renfrew, a powerful twin-screw hopper dredger, which will be fitted with the builder's patent sand pumping apparatus, similar to that supplied by them in connection with the dredging operations on the Mersey bar. This vessel will be constructed under the direction of Sir John Coode, K.C.M.G., of Westminster.

On the 9th inst. Messrs. Edwd. Withy & Co. launched from their shipbuilding works at Hartlepool the large steel screw steamer "Sydenham," built to the order of Mr. R. B. Stoker, London. This vessel is over 300ft. in length, and is built throughout of Siemens-Martin steel. She is built to the highest class of Bureau Veritas International Register. To make the vessel as far as possible unsinkable, the main and fore holds are divided by an iron water-tight bulkhead efficiently stiffened by iron grain divisions, and on the web-frame system, with cellular double bottom subdivided into water-tight compartments. The engines, which are of the triple-expansion type, have been constructed by Messrs. T. Richardson & Sons, Hartlepool, and there are two large single-ended boilers, constructed for a working pressure of 160lb.

On the 9th inst. the "Sir William Hartley," a new dredger for the European Commission of the Danube, built and engined by the Naval Construction Company, left Barrow for Sulina. Previously she had been thoroughly tested, with satisfactory results.

On the 10th inst. Messrs. Wm. Simons & Co. launched from their yard the "Mazatlan," a steel screw passenger steamer, built for the Mexican trade. The vessel has been constructed of Siemens-Martin steel to Lloyd's highest class, and is of the following dimensions:—Length, 150ft.; breadth, 22ft.; depth, 11ft. The vessel is lighted throughout with electricity. The engines, which were also made by the builders, are of the inverted triple-expansion type, with cylinders of 16in., 35in., 41in. in diameter, and a stroke of 30in. The boiler, which is constructed of mild steel, has a working pressure of 160lb. per square inch. It is provided with one of Kirkaldy's feed-water heaters. The propeller shafting is of Messrs. Vickers, Sons & Co.'s steel, and the propeller is of manganese bronze.

Notices of Meetings.

THIS WEEK.

Royal Institution.—Friday, June 26th, at 9 p.m. Faraday Commemoration Lecture by Professor Dewar, F.R.S.

Physical Society.—Friday, June 26th, at 5 p.m. Papers to be read: "The Construction of Non-Inductive Resistances," by Professor W. E. Ayrton, F.R.S., and Mr. T. Mather; "The Influence of Surface-Loading on the Flexure of Beams," by Mr. C. A. Carus-Wilson; "On Pocket Electrometers," by Mr. C. V. Boys, F.R.S.; "On Electrification due to the Contact of Gases with Liquids," by Mr. J. Enright, B.Sc.

PRICES CURRENT, 24th June, 1891.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: During the past week values of raw copper have still further improved, and the market continues firm. Large transactions are reported in Chili bars recently, and quotations are about 10s. higher per ton on the week. To-day's prices are £56 7s. 6d. to £56 15s. cash. Manufactured firm, at £67 to £68, "strong."

Tin continues very steady, and prices are the same as in our last report.

Lead: Quiet; values a shade firmer.

Spelter continues to advance, and is likely to be dearer, as stocks are everywhere small and the consumption increasing.

PIG IRON—BRAND "CARRON."

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Sulphate of copper has again receded a little, under pressure of second hand parcels for spot delivery; quotations for forward delivery remain firm. Sulphate of ammonia is still neglected. Carbonate and muriate of ammonia are in fair demand. Yellow prussiate of potash is steady, but the inquiry is rather easier. Bichromates of soda and potash have more attention, sales being made for early delivery only. Acetates of lead are firm. Nitrate of lead very dull.

We have received from Messrs. Alexander Shanks & Son, of 110, Cannon Street, London, E.C., and Arbroath, N.B., a copy of their weekly catalogue, which contains a very complete list of engines and boilers for land and marine purposes, pumps of various descriptions, and grab diggers, made by this firm. The marine engines comprise triple-expansion and compound types of various sizes, fitted according to Lloyd's requirements.

HOME INDUSTRIES.

LONDON, 25th June, 1891.

The Money Market.—The money market has gradually become very weak. There is practically no demand for accommodation, and bills are so scarce that, even at rates which are barely remunerative, the discount houses cannot get business enough to employ the funds at their disposal. In the Stock Exchange the Settlement, which began on the 24th inst., has afforded a good excuse for lack of business. But, apart from this excuse, there is no life in the market, the cheapness of money having failed to stimulate speculation, while investment purchases are made only cautiously and on a very small scale. Distrust is playing havoc with business. Not only is it rampant in each individual market, but London distrusts Paris, and New York has doubts about London. The only department in which there has been any activity this week is in silver securities, but doubts concerning the origin and permanency of the renewed "boom" in silver have checked the rise. Foreign stocks have been firm, but this has been due to manipulation in Paris in order to influence the price of foreign stocks at the Settlement here. Home railways continue lifeless and dull. American railways move spasmodically, the uncertainty and nervousness of Wall Street making any sustained movement impossible. Miscellaneous, industrial, and mining securities receive little attention in general, though particular stocks are subject to some purely professional speculation.

Great Northern Telegraph Company.—The monthly traffic returns of this company show that the receipts during the month of May were £26,000. The receipts from January 1st to May 31st, 1891, were £114,000, whilst for the corresponding months of 1890 and 1889 they were £105,800 and £106,800 respectively.

Postage of Newspapers.—On the 23rd inst. a deputation, consisting of a large number of newspaper proprietors, waited on the Postmaster-General at the House of Commons in order to lay before him certain statements with reference to the transmission of newspapers and periodicals through the Post Office. Mr. Henniker Heaton, M.P., introduced the deputation, and stated that the revenue of the Post Office had increased by £1,500,000 during the past six years. The Chancellor of the Exchequer received £400,000 more from the Post Office than in 1885. He asked that all newspapers and periodicals published at intervals of thirty-one days, instead of seven days according to the present regulations, should be treated as newspapers. He also advocated that the present regulation as to the amount of current news should be revised. In the United States periodicals which appeared only four times a year could be sent as newspapers, provided they contained information of public interest, and were not designed primarily for advertising. Newspapers could be sent to India from France at a third less cost than from England. Mr. Heaton asked that the maximum weight should be extended to 8oz., as newspapers were now often mutilated in order to reduce the weight below 4oz. Mr. W. T. Stead said that his magazine could be sent from New York to San Francisco for ½d., whereas the English Post Office charged 2½d. for its transmission in England. The postage to Australia on a 6d. magazine amounted to 1s. Mr. Arnold Foster said that only about 5 per cent. of the magazines distributed by his firm passed through the Post Office, the remainder being, at present, sent by railway and parcels conveyance. In America the postage of *Harper* was ½d., whereas the postage of the *Quiver* in England was 2d. Mr. Gill showed how the revenue of the Post Office was increased by the large number of letters sent in reply to advertisements. Mr. Leng, M.P., spoke against the giving of too much discretionary power to the Treasury. The Postmaster-General, in reply, referred to the Post Office Acts Amendment Bill, which was now before Parliament. The clause of that Bill which fixed the maximum weight of a newspaper at 1lb. he considered to be very liberal. There was only one journal in the United Kingdom which exceeded that weight. The Treasury warrant was always open to the criticism of Parliament. A clause had been inserted which enabled supplements to be distributed without the date being affixed. Instructions had been given to the English delegates to the Vienna Conference to see whether greater uniformity could not be obtained in the rates for the postage of newspapers for the Colonies.

Royal Meteorological Society.—At a meeting of this Society held on the 17th inst., Mr. Baldwin Latham, M.Inst.C.E., President, being in the chair, Mr. A. J. Hands gave an account of a curious case of damage by lightning to a church at Needwood, Staffordshire, on April 5th, 1891. The church was provided with a lightning conductor, but the author thought that when the lightning struck the conductor a spark passed from it to some metal which was close to it, and so caused damage to the building. Mr. W. Ellis read a paper, "On the Mean Temperature of the Air at the Royal Observatory, Greenwich, as deduced from the Photographic Records for the Forty Years from 1849 to 1888," and also gave some account of the way in which, at different times, Greenwich mean temperatures have been formed. Mr. Ellis also read a paper, "On the Comparison of Thermometrical Observations made in a Stevenson Screen with corresponding Observations made on the Revolving Stand at the Royal Observatory, Greenwich" From this it appears that the maximum temperature in the Stevenson screen is lower than that of the revolving stand, especially in summer, and the minimum temperature higher, whilst the readings of the dry and wet bulb thermometers on both the screen and the stand, as taken at stated hours, agree very closely together. Mr. W. F. Stanley exhibited and described his "phonometer," which is really a new form of chronograph designed for the purpose of ascertaining the distance of a gun from observations of the flash and report of its discharge, by the difference of time that light and sound take in reaching the observer. The instrument can also be used for measuring the distance of lightning by timing the interval between the flash and report of the thunder. A paper was also read by Mr. A. B. MacDowall, on "Some Suggestions Bearing on Weather Prediction."

MANCHESTER, 25th June, 1891.

River Pollution.—The Bill for the formation of a Joint Board for dealing with the question of the pollution of the streams in Lancashire and Cheshire has now practically been accepted. A committee of twenty-four members is to be elected by the County Councils of Lancashire and Cheshire, and the Councils of Manchester, Salford, Bolton, Bury, Oldham, Rochdale, and Southport. The Ribble is to be dealt with by a committee of sixteen members, and in each case the whole of the powers conferred by the Rivers Pollution Act are to be vested in the committee, the expenses of the necessary prosecution being defrayed from a fund to which contributions *pro ratâ* are to be made by the various bodies represented. The Corporation of Manchester has had a survey made of the streams affecting the city, with a view of ascertaining what manufactories were polluting those streams, and what steps were being taken to prevent pollution. The great difficulty in the way of private firms is that of obtaining a simple but effective apparatus which should be capable of dealing with the necessary volume of liquor in a short time. There is an opportunity for makers of filters who can treat works effluents rapidly and effectually. At present precipitation in tanks appears to be the only course open to them.

Health of Factory Workers.—Some light is thrown upon the result upon workers in textile factories of their working conditions by a report recently issued by the Medical Officer of Health for Blackburn. The deaths from various diseases included 253 weavers and 124 spinners and cardroom workers. 11·4 per cent. of the weavers, 6·4 per cent. of the spinners, and 2·3 per cent. of labourers die from phthisis and lung diseases. The report states that the three factors having the chief influence on the health of workmen are the temperature, the vitiated state of the atmosphere arising from respiratory impurity, and the humidity.

The Arts and Crafts Exhibition.—This very successful Exhibition was closed on the 20th inst., after having been open for eighty-one days, during which time the visitors numbered 242,268. A number of awards for exhibits have been made, and it is proposed to hold a similar exhibition at a future date.

The Ship Canal.—On the 19th inst. water was admitted into the canal cutting at Ellesmere Port, thus marking the approaching completion of the work. A depth of water of 26ft. now exists between Ellesmere Port and Eastham, a distance of 3½ miles, and, although the canal is not yet excavated to its full depth, the remainder of the work will be carried out by dredging. The water was admitted by a cutting in the embankment, the opening of the lock gates and formation of a deep sea channel having yet to be carried out. In all there are five dredgers at the disposal of the engineer, which can be put to work speedily. It is anticipated that the canal will be filled with water as far as the mouth of the Weaver during the month of July.

The Linen and Jute Trades.—The results of business this week have been somewhat disappointing both in the light and heavy descriptions of goods. Home trade is somewhat restricted owing to the near approach of stock-taking. One of the most important outlets of trade for Manchester firms is South America, but there has probably been no time when shipments to that country were so small as at present. A very great drawback to business with Brazil is the high price of the necessaries of life in that country. Prints from this district have advanced from 350 milreis to about 500 milreis per yard, and prices of cheap hosiery have increased in still greater proportion. In consequence of this there is no disposition amongst importers to operate, and the same remark applies to trade with the Argentine and with Chili. French spun flax yarns do not meet with such an extensive sale in this country as was the case several years ago. According to the statements of sellers, this falling off is due to a decline in the production of the Lille district, which at one time was a very formidable competitor with England. In the local warehouses stocks are not very large, and buyers do not seem anxious to operate.

GLASGOW, 25th June, 1891.

Engineering.—The steel works of the Calderbank Steel and Coal Company, situated at Calderbank, about three miles from Coatbridge, are now rapidly approaching completion, and will, it is anticipated, be in full operation by the beginning of August. The works are designed for an output of 50,000 tons of finished steel per annum, and are fully equipped with the newest type of plant, of exceptional strength and power. The company was inaugurated exactly twelve months ago, with a capital of £250,000, and a strong local directorate. The general manager is Mr. J. W. Waites. —The new works of the Lanarkshire Steel Company are now in active operation, attention at present being devoted to the manufacture of angles and bars. The plant comprises three Siemens-Martin furnaces of the latest type. The works are situated at the Flemington Station on the main line of the Caledonian Railway, where ample siding accommodation has been provided. A minor strike has occurred at the Blochairn Works of the Steel Company of Scotland. The dispute has been about wages, but only a small section of the workmen has been involved.—The Admiralty contract for the supply of platform weighing machines for five years has been secured by Messrs. Alexander Wood & Sons, Stockwell Street, Glasgow. No loose weights will be employed. Under this contract all the Government Dockyards will be supplied.

The Late Mr. James Young.—On the 18th inst. there died at his residence, Skelmorlie, in his eighty-second year, Mr. James Young, railway contractor. Mr. Young's first practical experience was in the early days of Scotch railways, when he acted as overseer of navvies on the Glasgow and Gamkirk Railway, which now forms part of the Caledonian system. For some years thereafter he was engaged as a general contractor, and did a large amount of useful work as a maker of roads and a builder of dykes. As the railway system developed he gradually obtained contracts of considerable importance. His first independent contract was the Calderbank section of the Monkland Railway, on the completion of which he was engaged for several years for the same company on contracts in the neighbourhood of Bathgate. He then entered into partnership with the late Mr. Robert Ward, in conjunction with whom he carried out two important contracts for the Caledonian Railway Company on what is known as the Rutherglen and Coatbridge branch. After this he constructed the Milngavie Railway and the eastern section of the Wemyss Bay Line from Port Glasgow to Ravenscraig, between 1860 and 1863. In 1866 to 1869 Mr. Young successfully carried out the western section of the Greenock and Ayrshire Railway, which passes through West Greenock and gives access to the Prince's Pier of the Glasgow and South-Western Railway Company. At the same time he carried out the Greenock Waterworks, including the large Gryffe reservoir, from which the town is supplied. His partnership with Mr. Ward being dissolved, he took into partnership his son, Mr. James Young, Jun. The most important contracts carried out by the firm were the Glasgow, Bothwell, Hamilton, and Coatbridge Railway, the North Monkland Railway, the Yoker and Clydebank Railway, the St. Andrews and Anstruther Railway, and lastly, the western section of the Glasgow City and District Railway from West Campbell Street to Stobcross. Mr. Young introduced into Scotland the American steam-navvy, which is now in extensive use. Mr. Young retired from business on the completion of the Glasgow City and District Railway in 1886.

Scottish Railways.—The Fortwilliam section of the West Highland Railway, extending from Fortwilliam to Treig, has been completed, and on the 18th inst. a train was run for twenty miles, the whole length of the section. The other sections of the railway are being pushed on rapidly.

Visit of French Railway Officials to Glasgow.—Thirty railway officials of the French railways, who are just now making a tour in this country, visited Glasgow this week. They were met by local railway officials, and conducted over the City and District Railway on the North British line, and subsequently visited several of the shipbuilding yards, including Fairfield and Clydebank.

Chemical Industry.—The manufacture of bichrome carried on under the Alkali Union at the Eglinton Chemical Works, Irvine, has been suspended on account of the low price of bichrome.

Minerals.—The pig iron market is absolutely quiescent, there being very little business, although there is a brisk demand for forward delivery for Cannel coal. The export trade is dull at the present moment.

Gold Extraction.—The results of a number of trials of the Macarthur-Forrest process worked by the Cassel Company at the Johannesburg gold fields were so satisfactory that at the beginning of this year the process was adopted for systematic work. It is reported that this has resulted in a considerable addition to the product, there being a large quantity of refractory ores in that region. Mr. Macarthur, of the Cassel Company, is now in South Africa. Mr. Pollok, of the Pollok Patents Company, is on his way to Queensland.

(From our own Correspondents.)

LIVERPOOL, 24th June, 1891.

The Liverpool Water Supply.—The long-promised supply of the Vyrnwy water has not yet reached the Liverpool mains, and it was stated at the meeting of the Water Committee yesterday that the present supply, instead of being made continuous, would most probably have to be further restricted. There appears to be some difficulty with the temporary pipe line which was laid a short time ago, and admittance to the precincts of the Prescot reservoir, into which the supply has to flow, is strictly forbidden. An unfortunate accident is also reported to have happened to the permanent works under the Mersey, the water of the river having burst in near the shield and flooded the tunnel. The arbitration case to

Digitized by Google

decide the claim of the original contractors for the construction of the tunnel—Messrs. Monk & Newell—against the Corporation of Liverpool for wrong determination of the contract and for damages is now being heard before Sir John Coode, with Mr. Meadows White, Q.C., as legal assessor, at the Westminster Palace Hotel, considerable interest being evinced in the evidence and the probable result.

SHEFFIELD, 24th June 1891.

The Iron and Steel Market.—Iron and steel works continue to be fairly employed, although there is no decided pressure of work. Orders for railway material are scarcely sufficient to keep the machinery going, and some of the older firms are looking forward to a period of slackness in the near future. Messrs. Ashbury's Railway Carriage Company are busily employed with goods waggons and passenger carriages for English and Irish railways. The substitution of iron axles for steel upon the Indian railways has not yet had any perceptible effect upon business in this town. Sheffield steel manufacturers are strongly of opinion that this step is decidedly retrogressive. There is no improvement to report in marine engineering. Orders for shafts and castings are almost completed, and there is little prospect of new orders for some time to come.

Engineers.—The Yorkshire Engine Company, of Sheffield, has just completed the roller path for one of the Manchester Ship Canal swing bridges. This is of cast iron in sections, each of which was machined separately, and with such accuracy that when bolted up the path was perfect and the joints imperceptible. This firm is also bringing out an improved form of coal cutting machine, which is capable of cutting in either direction, and is worked by compressed air or steam.

Agricultural Implements.—There is a brisk inquiry for agricultural implements, and makers of castings and forgings here are employed to the full extent of their capacity.

Cutlery.—Firms engaged in trade with America are very slack, and are not employed more than two or three days in each week. The home and colonial trade in edge tools is very fair.

Rawdon Sewerage.—The Rawdon Local Board have instructed Mr. W. H. Radford, of Nottingham, to prepare a scheme for sewerage and sewage disposal for the whole of the areas under their control. The population of the district is 3,500, and part of it is a residential district for Leeds and Bradford merchants.

CARDIFF, 24th June, 1891.

The Iron and Steel Trades.—The prospects in the steel trade are anything but cheerful. Makers have been turning their attention to rails, but orders are very scarce. Steel tin bars find no outlet now on account of the stoppage of the tinplate works. In the pig iron market there is a fair amount of business. Iron ore has been sold at 13s. c.i.f. Cardiff and Newport, 50 per cent. basis.

The Coal and Coke Trade.—The steam coal market is not quite so brisk this week on account of a falling off in the arrivals of tonnage. There is, however, a good deal of tonnage being chartered for loading during the next two weeks, and it is expected that prices will become firmer. Some cargoes of coal ready for delivery have been sold at a little less than the market price. Best quality is quoted at 15s. to 15s. 3d.; second, at 13s. 9d. to 14s. 6d.; third, at 13s. to 13s. 6d.; and fourth, at 12s. 6d. to 12s. 9d. Small steam, 5s. 3d. to 5s. 6d. Coke is in limited request. House coal is dull on account of the warm weather. The question of new docks is still much discussed in commercial circles. In many quarters it is felt that the time has arrived for the formation of a Harbour Trust, of which mention was made a few weeks ago. The Barry Dock and Railway Company intend to construct a new low-water entrance with a depth of 10ft. below the level of the dock. The coal shipments at Barry Dock for the half-year will certainly amount to more than 2,000,000 tons, an increase of 400,000 tons on the same period of last year.

BARROW-IN-FURNESS, 24th June, 1891.

Hematite.—There is a quiet trade in hematite qualities of pig iron, although prices show an improvement. Warrant iron is selling at 51s. 3d. per ton net cash, and makers are asking 53s. for parcels of Bessemer mixed numbers net f.o.b. The consumption is still greater than the output, with the consequence that stocks are being slowly reduced. Forty-one furnaces are still blowing and thirty-six are idle. There is less consumption of Bessemer qualities of pig iron, and little trade in forge and foundry qualities, while spiegeleisen, which is smelted at some of the works, is not in large request, although 20 per cent. qualities can be bought at 95s. per ton.

Steel.—A quieter tone is again noticeable in the steel trade. There is less business in Bessemer rails, although two of the largest makers in the district have sold largely for future delivery, but the rest of the makers are unfavourably situated. Heavy rails are at £4 7s. 6d. per ton, light rails at £5 10s., and colliery sections at £6 15s. per ton. In steel shipbuilding material there is not much business, nor is the demand in any sense equal to the capacity of production. It is hoped that the shipbuilding department of trade, as well as the business in steel blooms, slabs, and billets, will improve. Tinplate bars are, however, very quiet. The business in hoops and heavy steel castings is brisk, and there is every chance of a considerable development of this industry in the early future.

Iron Ore.—Little business is being done in iron ore. A cargo of native hematite was shipped last week from Barrow to New York, which contrasts with the importation of a cargo of Bilbao ore this week to this district where there is very little demand for local qualities of the raw material. Local ores are at 9s. 6d. to 9s. 9d. per ton net at mines.

Shipping.—A better tone has lately been noticeable in the shipping trade, but although the tonnage of metal exports are exceeding those of the corresponding period of last year, the aggregate tonnage of exports up to the middle of the present month is below that in the corresponding period of last year.

MIDDLESBROUGH, 24th June, 1891.

Pig Iron.—The iron trade is still in an unsatisfactory state. At the weekly market held on 'Change yesterday, there was a good attendance, but little business was done. No. 3 Cleveland G.M.B. was a little stiffer in sympathy with warrants. The general quotations for No. 3 makers' iron was 41s. per ton, and that price was paid by those who wanted it for immediate shipment, but iron for early delivery was quoted at 40s. 6d. by some firms, and at 40s. for August delivery. Middlesbrough warrants are—sellers, 42s. 4d., and buyers, 42s. 3d. per ton. The deliveries to Scotland of No. 4 foundry and forge iron are in fair quantities, though the difference in price between these qualities and No. 3 would have been thought to lead to a better demand. No. 4 foundry is quoted at 38s. 6d., and grey forge at 37s. 6d., but the latter can be got from sellers at 37s., which is 4s. instead of the usual 1s. below the usual price of No. 3. East Coast hematite is quoted at 50s. 6d. per ton for mixed numbers. There is still a large amount of iron going into the public stores to make warrants, and on the 22nd inst. the stock in Connal's was 133,983 tons, an increase for the month of 8,414 tons. It is probable that the stocks will not be much decreased this month, as in consequence of the approaching stocktaking local deliveries will be kept as low as possible until the end of the month.

Manufactured Iron and Steel.—There is little to report in connection with the finished iron and steel industries; indeed, it may be presumed that prices have now reached their lowest, for, though work has been irregular and orders scarce for the past few weeks, quotations have not altered. They are as follow:—Common bars, £5 12s. 6d.; best bars, £6 2s. 6d.; iron ship plates, £5 10s.; steel ship plates, £6; iron angles, £5 7s. 6d.; steel angles, £5 15s., all less 2½ per cent. for cash on the 10th of the month following delivery and f.o.t. at makers' works. Heavy steel rails are from £4 5s. to £4 7s. 6d. net at works.

Shipments.—The shipments of pig iron appear to be falling off for the latter part of the month, and during last week only amounted to 15,877 tons, as against 20,336 tons for the corresponding week of last year. The total shipments for June up to the 22nd inst. were 56,607 tons, against 58,927 tons during the corresponding period of May, and 56,018 tons up to June 22nd, 1890.

SUNDERLAND, 24th June, 1891.

Shipbuilding.—Thirty-nine vessels, of 84,058 tonnage, have been constructed during the present year. This amount shows a decrease of seven vessels, of 13,742 tons, when compared with the corresponding period of the year 1890. Messrs. William Doxford & Sons, Pallion, take the first place with five vessels, of 13,148 tons, three of which were "Clan Line" steamers, and the remainder very large sailing vessels. Messrs. Short Bros., Pallion, are second, with an output of six steamers, of 11,416 tons; and Messrs. J. L. Thompson & Sons, North Sands, are third, with four steamships, of 9,180 tons. Mr. James Laing, Deptford, has launched three steamers, of 9,138 tons; Messrs. W. Pickersgill & Sons, Southwick, two steamers and one sailing ship, of 6,790 aggregate tonnage; the Sunderland Shipbuilding Company, Ld., South Dock, two steamers, of 6,370 tons; Messrs. J. Blumer & Co., North Dock, three steamers, of 5,850 tons; Messrs. Osbourne, Graham, & Co., three steamers, of 5,672 tons; Messrs. Robert Thompson & Sons, Southwick, four steamers, of 5,488 tons; Messrs. Bartram, Haswell, & Co., South Dock, two steamers, of 5,113 tons; Messrs. J. Priestman & Co., Southwick, two steamers, of 3,743 tons; and Messrs. S. P. Austin & Son, one steamer and one sailing vessel, aggregating 2,150 tons. The Strand Slipway Company have not launched any vessel during this period.

River Wear Commissioners.—The report for last month was fairly satisfactory, although neither as to coal shipments or gross revenue was it equal to that of the previous month. From the river and docks 332,986 tons of coal were shipped, as compared with 325,784 tons in the month of May, 1890. The total revenue for the month was £11,364 10s. 11d., as against £11,182 4s. 7d. in May, 1890, an increase of £182 6s. 4d.

The Engineering Trade.—Much satisfaction is felt that the dispute at Jarrow has been settled, and that the local employers have been enabled to reinstate those members of the Amalgamated Society of Engineers who had been discharged. There are still some matters in dispute amongst seagoing engineers, as the conference held here on the 8th inst. had no definite result. On the 20th inst. the counter proposals of the shipowners were considered at a meeting of all the engineering societies, and steps are being taken to have a second conference with the employers.

NEWCASTLE, 24th June, 1891.

The Coal Trade.—At a meeting of coal owners and representatives of the Northumberland miners, held in Newcastle on the 20th inst., the claim of the miners for an advance of 10 per cent. on the wages rates was discussed, and at the close, the coalowners declared their inability under present circumstances to concede any advance whatever. This decision will, of course, be the subject of further discussion in the miners' lodges, but it is probable that in view of the general tendency to a decrease of business the claim will be withdrawn. The shipments of coal and coke at Tyne Dock during the week ending the 20th inst. amounted to 122,889 tons, being an increase as compared with the shipments in the corresponding week last year of 2,680 tons.

The Race Week Holidays.—In accordance with custom the whole of the industrial establishments in the district are closed this week, owing to the holding of the annual race meeting at Gosforth. This is the longest holiday period observed in this district throughout the year, and managers of works usually take advantage of it to carry out such repairs as may be needed to the plant and machinery under their charge. The stoppages of work through holidays and labour disputes that have taken place this year have exercised a most detrimental effect on business, and it is to be hoped that in the remaining six months there will be few or none of these interruptions.

Shipbuilding.—Messrs. Armstrong, Mitchell, & Co. launched from their Low Walker Yard on the 20th inst. a large twin-screw passenger steamer of 11,000 tons displacement, ordered by Messrs. McIver, of Liverpool. The vessel, which is named the "Ruthenia," is intended to be the first of a new line of steamers to trade between this country and Australia. Messrs. Wigham Richardson & Co. have also launched a twin-screw passenger steamer named the "Pelotas." This vessel is intended for the Brazilian coasting service. It is reported on apparently good authority that a few orders have been received since the beginning of the month. It is to be hoped that the report will turn out to be well founded, for empty building berths are becoming numerous, and an accession of work is needed.

Engineering.—The works of Messrs. R. Stephenson & Co., South Street, continue to be kept well employed on locomotive orders, and Messrs. Black, Hawthorn, & Co. are also well supplied with work of the same description. The tendency of business at the Elswick Ordnance Works is still towards dulness, and within the past week or two a further number of hands have been discharged. There have been ordered from Messrs. Tangye, of Birmingham, through the firm's Newcastle agency, four 22in. centrifugal pumping engines and three duplex pumps, for use in connection with the new pontoon dock which is being constructed by Messrs. M. S. Swan & Hunter for the Wallsend Pontoon Company, Ld.

The Fitters and Plumbers' Dispute.—This unseemly quarrel has at last been ended, or at all events a truce has been declared, and full work will once more be resumed after the race holidays. The trouble will no doubt arise again unless some effective steps are taken to prevent such needless stoppages, and it is to be hoped that action will be taken before another crisis of this sort occurs.

BELFAST, 24th June, 1891.

Shipbuilding and Engineering.—These trades are now in a better condition than they have been for a long time past. All the stocks are full, and there are enough orders to keep them so for some time to come. A large number of vessels of heavy tonnage are lying at the finishing berths for the purpose of repairs. Several contracts of this sort have had to be sublet to English firms, owing to pressure of work here. Messrs. Harland & Wolff are working day and night in almost all their departments. The York Street Flax Spinning Company are following the example of Messrs. William Barbour & Sons, of Hilden, and are fitting their York Road Mill with triple-expansion engines, which have been ordered from Messrs. Hick, Hargreaves, & Co., of Bolton.

The Linen Trade.—The tone of the market is at present very steady, although sales have not been large. The demand for yarns, however, still continues good. The growing crop of flax is generally good, but more rain is desirable.

Electric Lighting in Armagh.—Messrs. Ernest Scott & Mountain, Ld., of Newcastle-on-Tyne, have secured the contract for the electric lighting of the Armagh Spinning Company's mills in Armagh. The installation will consist of a "Tyne" compound dynamo and 380 incandescent lamps

The Society of Chemical Industry.—The annual meeting of the Society of Chemical Industry will be held at Dublin on the 8th, 9th, and 10th of July. During the meeting visits will be made to several of the works and distilleries, &c., in the district, among which we may mention Messrs. Power & Son's distillery and Messrs. A. Guinness, Son, & Co.'s brewery.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than the afternoon mail delivery on Thursday. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week. Small advertisements can, however, be accepted up to 6 o'clock on Thursday.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 26TH JUNE, 1891.

REPORT OF THE BULKHEADS COMMITTEE.

THE Report of the Committee appointed by the Board of Trade more than a year ago to consider the questions relating to bulkheads in ships has just been issued, and is, on the whole, one of the most important documents which has appeared in connection with the practice of shipbuilding for a very considerable time. It is published at a very opportune time, when the subject of safety and speed at sea is being discussed, and when ships are being designed which are to surpass in size and speed any of those at present running. Those who study the document will, in the first place, wish to know the names of its authors, for the position of these in their profession will, to a very large extent, determine the weight which is to be attached to their recommendations. Such a Report will have authority in so far as it is the result of special investigation, combined with general knowledge and experience. The Chairman of the Committee was Sir Edward Harland, M.P., and he had as his colleagues the late Professor Jenkins, of Glasgow University; Dr. Alexander Kirk, senior partner of Messrs. Robert Napier & Sons; Mr. Royden, M.P.; Mr. James Laing, of Sunderland; and Mr. James G. S. Anderson, of London; and we think that these gentlemen form a judicious combination of practical experience, theoretical ability, and commercial knowledge which ought to command confidence. The Committee were asked to report on the following matters:—(1) As to the manner in which ships shall be subdivided, so that they may float in moderate weather with any two compartments in free connection with the sea, and what rule there should be as to the proportion of freeboard of the water-tight deck next above that to which such bulkheads are attached as shall be sufficient to enable the ship to float. (2) As to the description of ship to which such proportions should apply as regards size and design. (3) Upon the construction of water-tight bulkheads, with a view to their resisting the strains which come upon them. (4) In what manner the surveyors of the Board of Trade can best determine the sufficiency of such bulkheads. (5) Under what restrictions may passage ways be permitted through such bulkheads. (6) Whether a transverse compartment, divided into two by a longitudinal bulkhead, should be treated as one or two compartments. (7) What particulars, drawings, and calculations should be furnished by the owners of ships to the Board of Trade when they desire to take advantage of the provisions of the Merchant Shipping Act, 1888, which gives exemption from carrying the full number of boats and rafts which otherwise would be required. (8) Whether, independently of the requirements of the preceding paragraphs, the Committee have any recommendations to make with reference to bulkheads, which would, in their opinion, contribute to the safety of life at sea. The Committee carried out their work very carefully, and did not content themselves with writing a report as the result of their own personal work and experience. They not only took the evidence of other experts, but had recourse to experiments of a crucial character. Large tanks were fitted up in their offices at Whitehall, so that the Committee might be in a position to elucidate any difficult point which might arise. The results of their observations are embodied in a series of curves and tables, which must be of immense value, as they relate to almost every description of craft and cargo. The Committee also submit a series of suggestions, by the adoption of which the advantages of the efficient subdivision of vessels by means of bulkheads may be secured.

We must refer our readers to the Report for details of the investigations and of the replies which the Committee have given to the various questions which were placed before them, as our space will only allow us to notice a few of its chief points. With regard to the first question, the Committee think that vessels may be considered able to float in moderate weather with any two adjoining compartments in free connection with the sea, if fitted with efficient transverse water-tight bulkheads, so spaced that, when two such compartments are laid open to the sea, the uppermost water-tight deck to which all the bulkheads extend, and which they call the "bulkhead deck," is not brought nearer to the water surface than a certain limit. This limit is indicated by a line drawn round the side of the vessel, at a distance amidships of $\frac{3}{100}$ths of the depth at side at that place below the bulkhead deck, and gradually approaching it towards the ends, where it may be $\frac{3}{200}$ths of the same depth below it. This line they call the "margin of safety line." Vessels in which the bulkheads do not extend to a continuous deck require a modification of the "margin of safety line," which is specially described in an appendix to the Report. The arrangement of plane transverse bulkheads necessary to satisfy the above condition may be determined with the aid of the curves and tables which are given in the appendix, or by separate calculations in accordance with the assumptions made in that appendix. These curves and tables show the maximum spacing of such bulkheads permissible in vessels of various descriptions and under various conditions, at any point in the length measured along the loadline from the fore-side of the stem to the afterside of the sternpost, in connection with any given freeboard measured from the bulkhead deck. The freeboard to be used is not necessarily that required under the Merchant Shipping Act, 1890, but may be any freeboard which, on the application of the shipowner, may be registered by the Board of Trade. Such freeboard the Committee call the "bulkhead freeboard," and the corresponding loadline the "bulkhead loadline." The tables were so arranged that the Committee did not consider it necessary to frame rules with regard to the proportion of freeboard in relation to the size of the vessel. The tables were prepared for vessels carrying cargoes such as coal, but curves have been prepared for cargoes of a low density. From these curves similar curves may be approximately deduced for cargoes of intermediate density. From an examination of the curve for an iron cargo it is obvious that, to require such a spacing of bulkheads in sea-going cargo vessels as would fulfil the conditions of the question of the Board of Trade under all circumstances of loading, would cause the holds to be too short for general trade. The Committee say that, after much consideration, they recommend that the arrangement of bulkheads in all the vessels specified in the different

Digitized by Google

grades should be fixed on the assumption that the vessels contain cargo, such as coal, occupying 47 cubic feet to the ton, sufficient, with the full complement of bunker coals on board, to immerse them to the bulkhead loadline, and so distributed as a whole that they may float on an even keel. Such cargo they have assumed to admit water to 40 cubic feet in every 100 cubic feet of the space which it occupies.

The first question is the most important of the eight put to the Committee, and they have devoted considerable space to its discussion. With regard to the second question, they reply that although all vessels, whatever their length, can be subdivided so as to be able to float in moderate weather with any two adjoining compartments in free connection with the sea, yet if small vessels were subdivided to that extent their holds would be so reduced in length as to impair their value for commercial purposes. As we have already indicated, the Committee, having regard to the exigencies of trade, recommend that vessels should be classed in six grades, and be fitted with bulkheads in the manner mentioned in the appendix. These grades include all the ordinary types of vessels. In reply to Question 3, the Committee supply a table of scantlings, and, if the bulkheads forming water-tight compartments be constructed according to these, they may be considered of sufficient strength to withstand the strains to which they are likely to be subjected. They point out, however, that such bulkheads should be efficiently secured to the outside plating by means of frames or angle-irons, and also to the deck to which they extend. They also answer Question 4 by stating that the surveyors of the Board of Trade may accept the designs and scantlings contemplated in the tables as sufficient, but other modes of construction may be allowed, provided that the Board of Trade is satisfied that the strength would not be less than it would be if they were constructed to the above-mentioned scantlings. With regard to Question 5, the Committee recommend that any passage ways through such bulkheads should be subject to very strict conditions—which they enumerate—and which, if adhered to, should prevent any danger therefrom. They think that a compartment subdivided by one or more longitudinal bulkheads should be treated as one compartment only, unless the Board of Trade has been satisfied that the divisions have been made thoroughly efficient, and provided that the stability of the vessel would not be seriously affected by one part of it being filled. Owners desiring to take advantage of any of any of the exceptions made in the Merchant Shipping Act in favour of efficiently subdivided vessels, should furnish the Board of Trade with the following particulars and drawings: (*a*) Longitudinal elevation in section, showing the sheer, the bulkheads, and the decks proposed; (*b*) plan and elevation of each bulkhead; (*c*) proposed bulkhead, freeboard, and corresponding loadline; also position of the side-lights. The Committee have nothing very important to suggest under the last question put by the Board of Trade, thus showing that the previous ones had been very carefully drawn up. They, however, make a few recommendations of a more or less general nature. Altogether the Report of the Committee gives evidence of having been thought out and drawn up with great care, and we commend it to the attention of shipowners and shipbuilders.

THE NORWOOD JUNCTION RAILWAY ACCIDENT.

In our last issue we gave a brief abstract of Major-General Hutchinson's report on the bridge accident at Norwood Junction. The facts disclosed in this report are by no means calculated to inspire confidence in the minds of the travelling public. We learn that as far back as 1876 "two identical girders at different parts of the same bridge were broken by an engine getting off the rails, and they (the Brighton Company) were then recommended to substitute stronger girders in their place, a recommendation to which unfortunately no attention was paid, or the present serious accident would have been prevented."

Surely in such cases as these, where the safety of hundreds of passengers at one time is at stake, the Board of Trade should have power to enforce its recommendations. Otherwise one is tempted to doubt their utility. For all practical purposes the previous admonition of the Board of Trade might just as well never have been given, since it has required a second accident, involving damage to property and passengers, to induce the railway company to carry out the necessary reforms. From the engineer's point of view, our first feeling, on reading the details of the dimensions and condition of the girder and the loads to which it was subject, was one of astonishment that it had lasted so long—viz., thirty-one years—in spite of excessive loads and a flaw reducing by 25 per cent. its nominal sectional area.

According to Major-General Hutchinson, the span of the bridge is 26¼ft., "and the engine which drew the express train," to which the accident happened, "would give a moving load equivalent to about 12·33 tons at the centre of each girder, and the permanent load being equivalent to about three tons at the same point, the girder, according to Board of Trade rules (first issued in 1859), should have had a breaking weight of"—

$$\begin{aligned} 6 \times 12{\cdot}33 \text{ tons} &= 73{\cdot}98 \text{ tons} \\ 3 \times 3 \quad \text{,,} &= 9 \quad \text{,,} \\ &\overline{\quad\quad} \\ &82{\cdot}98 \text{ tons} \end{aligned}$$

Major-General Hutchinson states that the "calculated breaking weight of the girder, according to the usual rule, would be, supposing the metal sound, about 71 tons." "But the existence of the flaw would reduce this by at least one-fourth, or leave the breaking weight not exceeding about 53 tons."

Now admitting this to be correct, the nominal factor of safety would be $\frac{53}{15{\cdot}33} = 3{\cdot}45$ referred to the total load, moving and permanent; but as, on a short bridge with high train speeds, the moving load is approximately suddenly applied, the real factor of safety would be considerably smaller, without taking into account shocks or jarring. It seems, therefore, extremely improbable that the girder was really as weak as represented, otherwise it could not possibly have lasted for so long a period. Moreover, the relative reduction of strength represented by the flaw was probably much greater than that due merely to the diminished sectional area.

Taking all these points into account, we are led to suspect that the girder was in fact much stronger than estimated by Major-General Hutchinson, and a closer examination of the figures given in his report confirms us in this view. The depth of the broken girder is given as 27in., the width of the bottom flange 20in., its thickness at the outside and centre respectively 1⅛in. and 1¼in., and the thickness of the web 1½in. to 1¾in. Now, if we neglect the additional transverse strength due to the web, and calculate the strength of the girder in the same manner that the strength of deep wrought-iron girders is generally treated, taking the effective depth at 25½in. we find the total tensile stress on the lower flange from the equation—

$$\tfrac{1}{2} \times 15{\cdot}33 \times 13{\cdot}375 \times 12 = 25{\cdot}5 \times \text{total stress},$$

whence Total stress = 48·25 tons.

The sectional area of the lower flange is $20 \times 1\frac{5}{8} = 32{\cdot}5$ square inches, and therefore the tensile stress per square inch $\frac{48{\cdot}25}{32{\cdot}5} = 1{\cdot}484$ tons. If we assume the ultimate tensile strength of the cast iron to be 8 tons per square inch, we have an average factor of safety $\frac{8}{1{\cdot}484} = 5.39$, and the breaking weight would thus be $15{\cdot}33 \times 5{\cdot}39 = 82{\cdot}64$ tons. According to the "usual rule," Major-General Hutchinson estimates this breaking weight at 71 tons (assuming the metal to be sound). It is not stated in the report what this usual rule is, but the method we have adopted of calculating the strength of the girder gives a result which is much below the true value, and is yet considerably in excess of that obtained by Major-General Hutchinson. As is well known, the transverse strength of solid cast-iron beams is very much greater than that which is based on the assumption that the ultimate stress in the extreme fibre, if the usual formula for solid beams applies, is limited by the ultimate *tensile* strength of the material. Besides this, the strength of the web has not been taken into account in our calculation, and this alone would add at least 8 per cent. to the preceding estimate (82·64 tons). Having regard to all these considerations, the breaking weight of a sound girder of the dimensions in question might very well have been 120 instead of 71 tons, or, allowing a reduction of 25 per cent. for the flaw, 90 tons instead of 53 tons. Even thus the factor of safety would be less than 6, which, for cast iron subject to repeated and suddenly applied loads, with occasional shocks, is too low. The engine, moreover, which caused the final catastrophe was not the heaviest passing over the bridge, for we read that the London and North-Western locomotives brought a load of 14·3 tons on the centre of each girder.

Cast iron, from its character, is quite unsuitable as a material for the construction of girder bridges, not merely because it may contain flaws externally invisible, but chiefly on account of the fact that it has no true elasticity and a very slight extensibility. Consequently, when it fails, the collapse is sudden, and no warning is given. Since August, 1883, the use of cast-iron girders, except in an arched form, has been prohibited by the Board of Trade for under-bridges on *new lines*. We suppose because it is an old line the London, Brighton, and South Coast Railway Company consider themselves justified in still retaining five cast-iron under-bridges on their main route between London and Brighton. If cast-iron girders are dangerous on new lines they must be still more so on old lines, and to allow their continued existence on the latter when they have long been prohibited on the former is an illogical blunder on the part of the Board of Trade, and unpardonable negligence on the part of the railway company. It is an aggravation, too, of the offence, that "no inspection of the bottom flanges of the girders from below had taken place since the bridge had been refloored about ten years ago." This neglect is explained, but not excused, by the circumstance that "the bridge was covered underneath with corrugated iron plates." To have removed these for the purpose of inspection, would—we suppose—have entailed undue trouble and expense. Yet the damage done to the train alone is estimated in the official report at £1,850. As it happens, the flaw which accelerated the collapse of the girder "was invisible to even careful inspection after the girder had been placed in position," but this does not absolve the company from the duty of regular inspection.

Altogether the chief lesson to be learned from the unfortunate occurrence is, that official prohibitions and recommendations are of little use unless the authority by which they are promulgated has the power and will to enforce them. This suggests, by the bye, the subject of continuous brakes; but that is another matter, into which we cannot now enter. Let us hope, however, that it may not be forced upon our attention by some further "shocking railway accident" of another kind.

THE ALKALI WORKS REPORT.

Mr. Fletcher's annual report to the Local Government Board and the Secretary for Scotland is always interesting reading, and the report for the year 1890 is at the present time of especial interest, as it is the first official report issued since the establishment of the Alkali Union. The Chief Inspector points out that it may be expected that any improvement, introduced and found to succeed at any of the works, will be rapidly extended to all, and that among the managers a wholesome emulation will be developed, tending much to raise the general standard of efficiency. He wisely abstains from expressing any opinion as to the working of the Alkali Union from a commercial point of view, but if his expectation of greater efficiency at all the works is realised, the Union will thus be beneficial to the industry in this country. Rivalry in trade, however, has in many manufactures brought about the same result, and it is difficult to realise that a monopoly, as far as England is concerned, will tend to raise the efficiency in the way which Mr. Fletcher expects. The history of the sulphuretted hydrogen difficulty in connection with the Chance-Claus recovery process, which has been alluded to from time to time, shows that the nuisance complained of has been much greater than was at first imagined. The eagerness with which nearly all the alkali manufacturers adopted the new process must have suddenly burdened the Union with a considerable amount of labour in remedying the evil which existed through the faulty plant of the vendors. In Widnes alone we read that eight manufacturers almost simultaneously commenced working the new process, and altogether fifteen large works started within a few months of one another, with plant costing in the aggregate £500,000. The loss of sulphur at first amounted to as much as 10 grains per cubic foot, and was nearly 20 per cent. of the total quantity of sulphur produced by the process. The efforts of the Newcastle Chemical Company to combat the nuisance have proved unsuccessful owing to the valves of the pumps suffering from the strain caused by the great volume of gases which had to be pumped through the deep columns of "slurry" or semi-fluid tank waste. The British Alkali Company have passed their gases over the pyrites burners, and have thus entirely obviated the

Digitized by Google

nuisance, but such a procedure diminishes the production of acid in the chamber to the extent of 10 per cent., and necessitates an additional consumption of nitre. It is hoped, however, that the gain of sulphur will be found to compensate for these items of loss, and thus demonstrate the value of this method of treatment.

The Hargreaves process also lends itself to the utilisation of the sulphur-charged waste gases, but many works found that it was more advantageous at the time to erect special furnaces in which complete combustion of the sulphuretted hydrogen to sulphurous acid was effected, this acid gas being afterwards allowed to pass away through the chimney of the works. Dr. Affleck, the special inspector at Widnes, reports that none of the noxious sulphuretted hydrogen now escapes. The public, however, should be informed that at the works at which these furnaces are in use, notwithstanding the enormous dilution of the gases with air, the total amount of sulphur passing into the atmosphere remains the same. From a sanitary point of view, we doubt if sulphurous acid is at all preferable to sulphuretted hydrogen. We hope in the report for the current year statistics will be collected by means of which the acidity of the gases escaping in each district from sulphuric acid chambers, chimneys, and from manure works may be compared.

The total amount of salt consumed in the Leblanc soda process in 1890 was 598,684 tons, which shows a slight increase over the amount, 580,827 tons, for 1889, but has not yet reached the large amount of 613,718 tons consumed in 1888. The ammonia-soda process, on the other hand, consumed 252,260 tons last year, which is a far larger quantity of salt than in any previous year, the consumption being 219,279 tons in 1889 and 212,181 tons in 1888.

With regard to rival processes, the report states that the method devised by Messrs. Parnell and Simpson, of which so much had been expected, has now been abandoned, whilst that devised by Messrs. Haddock and Leith is favourably commented upon by Dr. Affleck. Mr. Gossage, of Widnes, and Mr. James Simpson, of Liverpool, are also both busily engaged upon commercial trials of their new processes, in neither of which is lime required, nor is any tank waste produced. In concluding this part of his report, Mr. Fletcher alludes to the electrolytic processes, and shows that "every improvement in the steam engine or other motor, or any advance in the construction of the dynamo, brings nearer the day when the splitting up of the salt may be accomplished as a simple act of electrolysis."

The smoke abatement question is also briefly discussed in the report, which contains many suggestive remarks thereon, and we commend a careful reading of this portion of the report to those of our readers who are interested in this question.

TELEGRAPHIC COMMUNICATION WITH LIGHTHOUSES.

We mentioned some time ago that the subject of the importance of telegraphic communication with lighthouses had been discussed before the Associated Chambers of Commerce, and that it was resolved to present a memorial to the President of the Board of Trade, setting forth that, inasmuch as a sacrifice of life and property takes place yearly on the coasts of the United Kingdom owing to the absence of prompt information of ships being in distress or wrecked, it is desirable that a system of telegraphic and telephonic communication be established between coastguard and lifeboat stations, lighthouses and lightships, and the general telegraphic system.

A few days ago a deputation waited on the President of the Board of Trade to present the memorial, and to urge upon him the necessity for attention being paid to the various matters mentioned in it. Colonel Hill, M.P., who introduced the deputation, pointed out that it was well known that from time to time there were disastrous wrecks around our coasts, attended with a lamentable loss of life and property, which might have been prevented if assistance could have been rendered with promptitude. In the majority of cases that assistance could have been obtained, for it existed in nearly all our ports in the shape of steam tugs and lifeboats at various stations, rocket apparatus, and other means. What was required was some means of letting those various stations know the necessity that existed for their help. There should, he urged, be telegraph and telephonic communications with the general system of the country, and the arrangements could be utilised, not only for the purposes of the mercantile marine, but also in time of war when they would be most valuable to the naval and military authorities. The Associated Chambers of Commerce had prepared a list showing where communication with the telegraphic system of the country was most needed. The places given in the list were: St. Agnes, Scilly, Start, St. Alban's Head, Dungeness, North Foreland, Cape Clear, Flamborough Head, Rattray Point, South Stack, St. Anne's, and Lundy Island. The expense had been estimated at £100,000, and Colonel Hill believed that even the expenditure of a very much larger sum than that would be justified if the present lamentable loss of life could be prevented. He pointed out that the expenditure would not be altogether unprofitable, because he was quite sure that some revenue—it was impossible to say how much—would be derived in consequence of the increased means of communication and intelligence that would be afforded.

After various other members of the deputation had spoken in support of the deputation, the President replied that, while he could not assent to their request at once, he was very favourably disposed towards it, and was willing to arrange for experiments being made to ascertain the difficulties connected with the question and the best methods of overcoming them.

This is possibly all that can be expected in the meantime. It is to be regretted, however, that the question of the expense connected with the arrangements and the experiments was not faced in a more liberal spirit. When any class or set of individuals receive special benefits it is only right that they should be expected to pay for them, but arrangements which are national should be paid for out of the national Exchequer. The President of the Board of Trade practically shirked the question, and hinted that the expense of the experiments ought to be paid out of the Mercantile Marine Fund, but as that fund has for some time been practically in a state of bankruptcy, the suggestion practically means that they should be paid for out of the pockets of the shipowners. Some years ago all tolls were taken off the public roads, and, if such a measure was expedient, then it is equally expedient to take steps which will add to the safety of our merchant shipping and to the strength of our army and navy. It is of the utmost importance that our military and naval authorities should have the earliest possible intelligence in the event of war, and also the means of communicating with all outlying points, and thus be able to arrange for the most effective disposition of their forces. We hope, therefore, that these authorities will unite with the Board of Trade, and come to an arrangement which will not only meet all their requirements, but also at the same time add to the safety of our mercantile marine.

DECIMAL WEIGHTS AND MEASURES.

For several years the "decimal question" has been quietly slumbering, but the development of foreign competition and other causes are now forcing renewed attention to it. The subject is certainly one of great importance, and it may be well to give a short statement of the present position of the matter.

If our coinage, weights, and measures were decimal, fractions could be added, subtracted, multiplied, and divided in the same way as whole numbers, and compound arithmetic would be superseded. From an educational point of view the advantage of such a change would be immense, and during the past year many of the leading School Boards petitioned the Education Department in favour of decimals being taught on completion of the four simple rules. Chiefly in consequence of this, the New Code (1891) provides that: "The scholars in Standards V., VI. and VII. should know the principles of the metric system, and be able to explain the advantages to be gained from uniformity in the method of forming multiples and sub-multiples of the unit." It is no-doubt an important step to familiarise the rising generation with the metric system, always supposing that the weights and measures of this system are to be generally used. If the metric system is not to be adopted the question will naturally be asked, Why should our overworked teachers and scholars have this additional burden cast upon them? The educational gain will be great if we adopt the metric system, instead of our odds and ends of incongruous and perplexing weights and measures; but the gain will be greater still if we also have a decimal coinage. As a question of practical politics it will not do to attempt too much, and there appears to be a general agreement among the advocates of the proposed reform that the weights and measures should be dealt with first, and the coinage afterwards. This opinion is strengthened by the fact that the last Royal Commission on Decimal Coinage reported in 1857 that it was undesirable to change the coinage "while our weights and measures remain as at present, and so long as the principle on which their simplification ought to be founded is undetermined."

Various proposals have been made for decimalising some of our existing weights and measures, but the Select Committee of 1862 (on Weights and Measures) pointed out that "it would involve almost as much difficulty to create a special decimal system of our own, as simply to adopt the metric system in common with other nations. And if we did so create a special national system we should, in all likelihood, have to change it again in a few years, as the commerce and intercourse between nations increased, into an international one." The Weights and Measures Act, 1878, has led the way by providing for the verification of metric weights and measures used for purposes other than trade, and sets forth the equivalents in imperial weights and measures. More recently the Board of Trade Standards Department has obtained metric standards of the highest scientific precision.

Many persons think the metric system simple, rational, and good, but fear trouble if we adopt the French names usually associated with this system. The French metric tables are no doubt complete and symmetrical, but in the ordinary affairs of domestic and commercial life barely a third of these names are used, even in France. In the elementary schools of Germany only nine names are taught for the metric weights and measures. If nine names are sufficient for Germany, there is no reason why we should have more.

The Select Committee of 1862 reported very strongly in favour of the adoption of the metric system, and it is urged that, good as their reasons then were, the need for the change is now very much greater, and it could be effected more easily than thirty years ago. Since then elementary education has been made compulsory, and is controlled by the representatives of ratepayers, under Government supervision. The School Boards wish for the change, and we have seen that experience in other leading countries has shown that the French metric tables, formerly proposed, can be greatly simplified. Apart from these considerations, there is the important fact that, excluding our own dependencies, the United States, and Russia, all the civilised countries of the world (with an aggregate population of nearly 330 millions) have now adopted the metric weights and measures. Put in another way, nearly 60 per cent. of our imports (excluding British possessions), and over 70 per cent. of our exports, come from and go to countries which have adopted the metric weights and measures. Not only is this so, but the foreign makers who compete with us come chiefly from countries where the metric system is used exclusively. Thus, while our foreign customers are troubled and perplexed with our absurd weights and measures, our competitors are able to offer them goods and machines in terms of the only weights and measures with which our customers and competitors are familiar.

Our Chambers of Commerce are all in favour of the proposed change; and when a joint deputation of the London Chamber of Commerce and the Decimal Association waited on the Chancellor of the Exchequer the other day, he admitted that the change would be an improvement, and that on theoretical grounds it was right. He did not even discuss the question on its merits, and merely referred to the difficulties of effecting the change. On this point the experience of other countries is reassuring, and the best example is probably that of Germany. In that country four years were allowed within which to effect the change, but as a matter of fact it was over practically in a few weeks. There certainly appears to be a *primâ facie* case for adopting the metric weights and measures without further delay, and it seems desirable that a Select Committee should be appointed to consider the question in all its bearings, and especially in the light of our present requirements. Over 150 Members of the present Parliament signed a petition for further inquiry by a Royal Commission or Select Committee, and many other Members are known to be in favour of such a course. The Education Department has already ordered that the metric system shall be taught in the primary schools; the Chancellor of the Exchequer has just stated that the Government will not oppose the appointment of a Select Committee; and it now remains for the pressure of public opinion to make itself felt through the usual channels.

We may say that we are indebted to the Decimal Association for some of the information we have now given; and if any of our readers desire further information on any point they will do well to write direct to its London Office, Botolph House, Eastcheap, E.C.

PROPOSED NEW RAILWAYS IN DUMBARTONSHIRE.

It seems as if Dumbartonshire were to have a large addition to its railway facilities, for the Caledonian and the North British Companies have each been successful in passing their schemes through the ordeal of Select Committees of the House of Commons. The schemes are, to a certain extent, competing, but the former is by far the more important of the two. The proposed schemes of the North British Company are designed merely to give

Digitized by Google

access to some works in Dumbartonshire, and to improve the North British communications in the Vale of Leven. The Caledonian scheme, however, is much more extensive, and continues the present line from Stobcross Docks, through Partick and Whiteinch, two populous suburbs of Glasgow, which were previously without adequate railway communication. Passing along the river side, at such a distance as not to interfere with the shipbuilding yards, but rather to serve them, it goes on by Bowling and Dumbarton to Lock Lomond, and finds its terminus on the Ross estate, at a distance of 26 miles from Stobcross. The only serious objection which was taken to it was that it would prevent the development of the line which already goes to Yoker and Clydebank, but the advantages of a direct connection with the Lanarkshire coal and iron districts were too great to be put aside in the interests of a local line. One interesting feature in the plan is the formation of a loop line which will serve to connect a large suburban district with the centre of Glasgow. The Glasgow Central Railway is now being constructed from the Central Station to Kelvinside, and it is proposed to bring it round in a circle to Stobcross, and on that part of the line to have an omnibus service of trains, which will enable a large number of people in business to live conveniently in a suburban district. The Caledonian Company seems disposed to meet all opposition in a conciliatory spirit, and we hope that this will cause that opposition to be so modified that the Bill will pass the House of Lords without much difficulty.

Letters to the Editor.

THE STEAMSHIP OF THE FUTURE.

To the Editor of "Industries."

Sir,—May I be permitted to suggest that speed is not everything in crossing the Atlantic. Other things being equal, I would rather cross quickly, but the temptation of making quick passages leads the skippers to run at dangerous speeds through fogs. During a fog the engines are signalled to go at "half speed," but this is a complete delusion. The last few miles an hour of a large steamer absorb a great deal of power. The result is that a very considerable reduction of engine power produces a very slight reduction of speed. The throb and tremble vanish, and you feel as if you were on board a sailing ship in a gentle breeze, but, on counting the revolutions of the engine, you find them running considerably over fifty. Everybody on board feels as if the steamer were progressing most circumspectly, whereas she is shooting along at over 15 knots. I have none of the instincts of a sportsman, and I do not care to risk my life by gliding quickly through a fog merely to escape a dull Sunday on board by securing a still duller one in New York.

Yours, &c.,
Liverpool, 22nd June, 1891. Engine.

IMPROVED COMMUNICATION WITH THE EAST.

To the Editor of "Industries."

Sir,—Referring to your notices of the quick passage made by the new steamer, the "Empress of India," between Yokohama and Vancouver, and the effect which the improved line of communication would have on the mails and traffic for the East, I have been informed by a friend, who was a passenger in her, that the new steamer and the new route have at once become very popular, and that every berth was occupied during the first voyage. The shortness of the time occupied is of course a great recommendation to business men whose holiday is short, or whose engagements are pressing. It has not yet been reduced to three weeks between Yokohama and London, but the mails shipped by the "Empress of India" were delivered in London twenty-seven days after leaving Yokohama. The comfort and arrangements of the steamer were everything that could be desired, while little or no trouble was given to the passengers at the points of connection on their journey. The railway part of the journey is much more enjoyable than that across the States, the scenery being very much finer, and the inconvenience and discomfort of the alkali plains, and the general monotony of the Western States of the Union after crossing the Mississippi, are avoided. Moreover, Britons have the satisfaction and pleasure, which in themselves are no mere matters of sentiment, of travelling the whole way under their own flag.

It is well that you should direct the attention of your readers to such matters, for they very often have more substantial results on industry and trade than matters relating to scientific or technical details.

Yours, &c.,
London, 22nd June, 1891. Far East.

TRUSTS.

To the Editor of "Industries."

Sir,—You have done excellent service in directing your readers to some of those broader aspects of industrial subjects which are too apt to be overlooked by the ordinary man of business and by the practical politician. The article in your issue of the 22nd ult. on "Trusts" was very much to the point, and will help to moderate the impression made by Mr. Plimsoll, who is always enthusiastic—some might say, hysterical—on all the subjects which he takes up. It cannot be doubted that trusts, or other similar combinations, economise both labour and money; the question for us to consider is whether the power which large combinations of capital at present possess is one which ought to be in the hands of private individuals for their own selfish ends. Free competition is at an end in many cases, and it looks as if the whole fabric of economic science will require to be placed on a new basis. We have certainly reason to modify our belief in the possibility of universal happiness and leisure flowing from the mechanical increase of our total production under a *régime* of unrestricted individual or capitalistic competition for its products.

When the Factory Acts were first proposed, the economists were, almost to a man, hostile to what they called restrictive legislation, and so, of course, were the capitalists. But, as the Duke of Argyll has remarked in his able book on "The Reign of Law," this opposition was not in the main due either to selfishness or indifference. False intellectual conceptions—false views both of principle and fact—were its real foundation. Some of the ablest men in Parliament, who were wholly unaffected by any bias of personal interest, declared that nothing would induce them to interfere with the labour which they called "free." Had not the working classes a right to employ their children as they pleased? Who, they argued, were better judges than fathers and mothers of the capacities of their children? But the pale faces of the little children, stunted and outworn, were sufficient arguments to enable the promoters of the Factory Acts to carry them in spite of all opposition, and in defiance of what were alleged to be inevitable economical principles.

Similar considerations for the welfare of the community to those which influenced the Legislature in passing the Factory Acts, would justify legislation to restrain capitalists, "rings," and trusts. Whether the fear of this, combined with the wish to conciliate the public by showing that, on the whole, they are a benefit to the people at large, may, as you think, be trusted to keep the trust question in check for some time to come, can only be found out from experience, but, in any case, it is well that the attention of our legislators and of the public should be directed to it.

Yours, &c.,
Newcastle, 23rd June, 1891. Liberty.

THE USE AND ABUSE OF MATHEMATICS.

To the Editor of "Industries."

Sir,—I have followed the discussion which has appeared in your journal on "The Use and Abuse of Mathematics" with much interest and with considerable profit. Your last correspondent on the subject, "Engineering Demonstrator," sagely remarks that, after reading the letters which have appeared on the subject, his belief has been strengthened that the value of an opinion depends, to a very large extent, upon the man who gives it. The majority of people arrive at this conclusion at a very early stage in their career, and that without any lengthened correspondence. The correspondence, I understand, was started for the purpose of ascertaining the place which mathematics should take in the training of engineers, and from that some of your correspondents have wandered considerably.

John Scott Russell, who was an accomplished mathematician as well as a distinguished engineer, said that "for a mere philosopher and for a practical mechanic, the science of physics must be taught in quite a different way. Certain elementary principles are, no doubt, the same for all men and all circumstances, but that is only the purest and most abstract science. To the man of science, the science itself is the end and aim; to the technical man, science is the mere tool and instrument, and what he wants to know is not the mere science only, but the means of shaping it to his end, and the best way of using it so as to achieve his purpose." This seems to me to express very clearly the position which mathematics ought to take in the training of engineers. In a letter to you on this subject one writer quoted an opinion of Professor Kennedy, to the effect that "he had no hesitation in saying that a man's knowledge of mathematics ends exactly where his ability to work problems ends; everything beyond that is useless, so far as his profession goes, and is even liable to have, in certain cases, disastrous consequences." Your correspondent, "Engineering Demonstrator," says that Professor Kennedy now ranks as a chief among consulting engineers, and that he has upon his staff at least one man who was among the first twenty in a recent mathematical tripos at Cambridge. He, no doubt, knows that Professor Kennedy had no special mathematical training, and that his mathematical knowledge has grown with his engineering experience; in fact, that the problems to which he applied his mathematics were not those artificial ones which are to be found in books, but the actual problems of engineering practice, and as he has risen in his profession so has his knowledge of mathematics extended. It has thus been real and thorough, as his position as a consulting engineer now shows.

Few engineers ever require much beyond elementary geometry, algebra, and trigonometry, and their applications. A stage higher would include the elements of analytical geometry and of the calculus. In the latter, however, almost all that engineers ever want can be done by the aid of elementary arithmetic, or by graphic or mechanical methods. In fact, in every department the problems should, if possible, be solved by analytical, graphic, and mechanical methods, which should thus be made to check and illustrate each other, and render their meanings plain to the students. In every department of engineering the same methods should be adopted. In the lecture rooms the students should get the theory of their work, in the drawing office they should learn to delineate principles and results graphically, while in the laboratory they should conduct experiments to illustrate or test these principles or results. If this were done they would soon find the real use of mathematics, and they would avoid the worst abuse, which, as your correspondent points out, consists in not using mathematics at all.

Yours, &c.,
Bombay, 5th June, 1891. Scrutator.

PNEUMATIC GUNS AND PROJECTILES.

The Americans have recently paid considerable attention to the pneumatic propulsion of shells and projectiles, as they have perceived the great advantage in case of war of being able to throw dynamite or other high explosives into an enemy's position whether at land or sea. The outcome of this has been the Zalinski pneumatic gun, for which a special vessel—the "Vesuvius"—has been constructed. This powerful weapon is, after all, however, a costly machine, each gun requiring a number of mechanical contrivances, more or less easily put out of order, and necessitating a motor of some kind, and air-compressing machinery. The barrel of the Zalinski gun is of very great length, and, while there is no doubt that in certain situations and under special conditions it would prove a powerful auxiliary against an enemy's fleet, it is practically useless in the field.

It therefore has been left for Mr. J. Elton Bott, of Manchester, to invent and perfect a pneumatic shell which seems equally adaptable for naval, field, or siege guns, and that with only a slight alteration of the gun breech and firing mechanism of ordinary guns. This pneumatic shell would appear to have the merit of being both simple in construction and efficient in action. It is carried in the ordinary tumbril of a field piece, and is perfectly safe, as it is simply a strong metallic cartridge containing the impelling charge of compressed air or gas at the rear of the chamber containing the explosive. When required to be used it is inserted in the breech of a gun in the usual manner, as in a quick-firing gun, when a simple turn of a lever instantaneously releases the air or gas, and the shell or projectile, which contains, in the forward chamber, a charge of dynamite or other high explosive, is sent with deadly effect in the required direction. In this operation no smoke is made, there is practically no noise, and the gun works perfectly cool and clean.

If the "Blanco Encalada," for example, had been equipped with a few small pneumatic guns, or guns adapted for firing the pneumatic shells invented by Mr. Bott—and made by Messrs. J. Elton Bott & Co., Limited, Cornwall Street, Openshaw, Manchester, the Chilian ironclad would have been able to fight practically noiselessly, and absolutely without smoke or heating of the gun barrels, while showering deadly missiles against the torpedo boat flotilla.

Extensive preparations are being made for the manufacture of pneumatic guns and shells by Messrs. J. Elton Bott & Co., as the inventor, after perfecting—at his own expense—both his gun and shell, has been fortunate enough to secure the co-operation of a number of prominent gentlemen, and, with their assistance, a series of tests were made before several Government officials on the estate of Mr. Geo. H. Cammell, of Hathersage, near Sheffield, the results being very satisfactory. The guns and some of the shells fired at the Hathersage tests are now at Cornwall Works, previous to being sent to the Royal Naval Exhibition. Messrs. J. Elton Bott & Co., are now constructing a large pneumatic gun for naval purposes, with a service of pneumatic shells. This gun when finished is intended for the naval service, and will be a very powerful weapon.

The following is an extract from the patent specification of the inventor, and will explain the nature of the invention:—

The invention "consists in providing a rear chamber to shells and other projectiles, which rear or auxiliary chamber is filled with compressed air or gas at a high-pressure. . . . . The rear or auxiliary chamber in each shell or projectile is constructed so that a proper charge of compressed air or gas is introduced through an orifice in its base, preferably in the manner in which carbonic acid gas is introduced into bottles of soda water, so that when such rear or auxiliary chamber is filled with air or gases at a pressure equal to that of the compressing machine, a lead, leather, rubber, or other suitable form of valve or plug, falls and closes the said orifice, thus enabling the shell or projectile so charged with compressed air or gas to be removed from the machine when it is ready for use in cannon, mortars, guns, and rocket apparatus. It is intended to load the shell or projectile in the ordinary manner with its explosive charge, which can be exploded either by contact or by the usual forms of fuses. The method of using the improved self-propelling shell or projectile is as follows:—After placing the shell or projectile in the muzzle or breechloading weapon from which it is to be expelled, a pin in the breech of the weapon is operated so as to force back or cut away the retaining valve or plug of the shell or projectile, when the compressed air or gas is immediately released, and by impinging upon the breech of the weapon causes the shell or projectile to be rapidly ejected from the muzzle of the weapon, thus dispensing with the usual gunpowder cartridge."

Mr. J. Elton Bott has also invented a novel method of constructing artillery, according to which the pneumatic gun now on exhibition at his works was made. If successful when applied to large guns, it will partially revolutionise the manufacture of ordnance, as by this method all the dangers of unequal shrinkage are avoided

AN IMPROVED UNSINKABLE SELF-RIGHTING BOAT.

THE accompanying illustrations, Figs. 1 and 2, represent a steel boat in elevation and plan respectively, which is being introduced by Mr. W. Wells, of 50, Commercial Street, Leith, and which is claimed to be absolutely unsinkable and instantaneously self-righting. The fore and aft sections of the boat are constructed in the form of hollow cones, and are thoroughly air and water-tight. These are slightly flattened and laid horizontally, and, owing to their peculiar form, impart strength and rigidity to the boat as a whole. The inventor claims that these boats are eminently suitable for pleasure purposes of every description, as they maintain their buoyancy when filled to the gunwale with water; and even if turned bottom upwards they instantly right themselves. These boats would appear to be especially suitable as an addition to the life-saving equipment of vessels, as, in case of emergency, they could be thrown overboard without the formality necessary with boat-lowering gear in use with ordinary punts or dinghies, and would instantly right themselves. The boats are put together in sections, and can be disjointed for transportation, and, it is stated, that should both the water-tight compartments be pierced below the water line, the boats would still remain buoyant. The boats are exceedingly light, one 12ft. long and 3ft. beam, with oars, masts, and sail, only weighing 3 cwt. We are informed that these boats have successfully undergone severe tests in the Firth of Forth.

ELECTRO-MAGNETIC GAS CONTROLLER.

THE accompanying illustration represents a part sectional elevation of an apparatus invented by Mr. J. M'Laren, 7, George IV. Bridge, Edinburgh, and intended for use in buildings lighted electrically, but where gas is also laid on in case of failure of the former light. The apparatus will automatically turn up the gas in case of failure of the electric light, and in the event of the latter coming on again will immediately lower the gas, thereby avoiding considerable inconvenience and effecting a great saving in gas. The construction of the controller is such as to require very little description, and is entirely self-

contained. The globe valve A shown in the upper portion of the illustration is fitted in the gas main, and is provided with a disc valve B with prolonged stem C, on which is fitted an armature D. The lower portion of the apparatus consists of a pair of electromagnets E, connected to the electric light mains, which, when the current is on, attract the armature and maintain the valve in its closed position. Should, however, the electric current in the mains fail, the armature will be released, and with it the valve, owing to the action of the spring H, thereby allowing a flow of gas to the burners. The small by-pass valve F is provided to allow a small quantity of gas to pass when the main valve is closed, so as to keep up a pilot light in the burners. The main valve is also capable of adjustment by means of a set screw G.

AN IMPROVED UNSINKABLE SELF-RIGHTING BOAT.

CONSTRUCTED BY MR. WILLIAM WELLS, ENGINEER, LEITH.

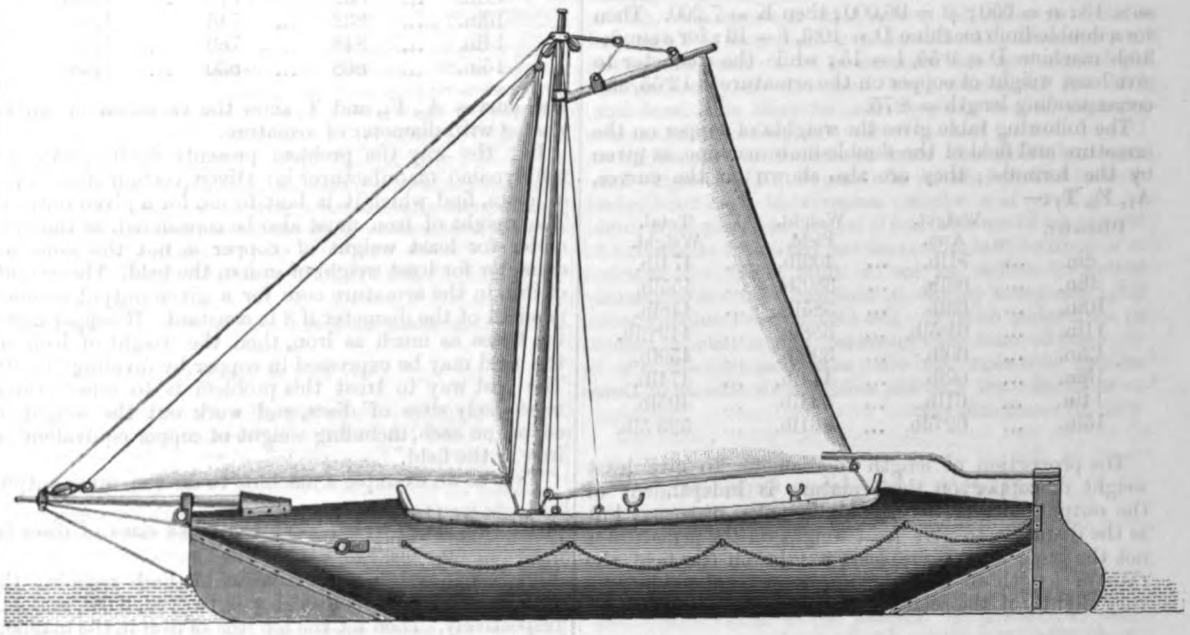

FIG. 1.—ELEVATION.

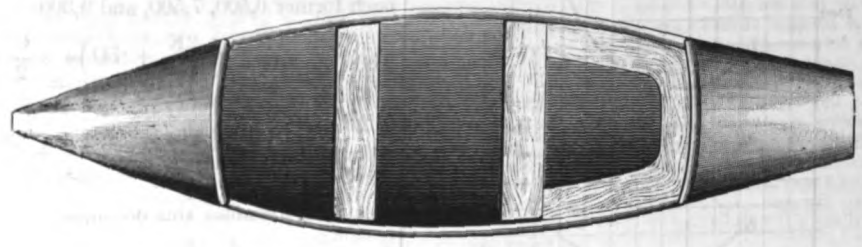

FIG. 2.—PLAN.

THE RELATION BETWEEN WEIGHT OF COPPER AND DIAMETER IN GRAMME MACHINES.

By R. B. ROGERS.

THE weight of copper on an armature is equal to the mean length of a turn in inches multiplied by the number of turns multiplied by the sectional area of the copper multiplied by ·32lb. The weight on each former is equal to the mean length of a turn multiplied by the ampere turns multiplied by ·32lb. and divided by the current density. This must be multiplied by the number of formers to give the total weight of copper on the field. Then total $W = ml$ (arm.) $\times n \times a \times \cdot32 +$

$$\frac{ml\text{ (field)} \times AT \times \cdot32 \times \text{number of formers}}{c.d.}.$$

The mean length of a turn on a two-pole Gramme armature is equal to twice the length of the core plus twice the radial depth of core plus an allowance for the commutator connections and the depth of the winding. If the radial depth is ·2D, the mean length may be taken as $2l + \cdot7D$. The number of turns is a function of the diameter and the current, and may be written mD, where m is a coefficient depending on C. The area is equal to the current in each bar divided by the current density. For rectangular magnets, with breadth measured parallel to the spindle equal to the length of core, the thickness would be about ·28D and depth of winding ·21D for a double-limb field of the Crompton type, and the mean length may be written $2l + 1\cdot4D$. For a single-limb field with magnets double the thickness, and the same depth of winding, this would be $2l + 1\cdot96D$. The ampere turns increase as the diameter increases, and if the air space increases as the diameter, the ampere turns may be written aD, where a is a number which may be taken as constant for machines of similar proportions but different diameters. Then, if x = current density in armature and y = current density in field,

$$W\text{ (total)} = \frac{(2l + \cdot7D)m\text{D}\frac{C}{2} \times \cdot32}{x} + \frac{(2l + 1\cdot4D)a\text{D} \times \cdot32 \times 4}{y}$$

for a double-limb Gramme field.

If the output of a machine and induction per square inch are fixed, nA = constant where A is the total area of both sides of the core. If β = induction per square inch, N = revs. per minute. $Ea \times 10^8 = n\text{A}\frac{N}{60}\beta$;

$$n\text{A} = m\text{D} \times l \times \cdot4\text{D} = \text{K} = \frac{Ea \times 10^8 \times 60}{N \times \beta}\ ;\ l = \frac{\text{K}}{\cdot4m\text{D}^2}.$$

Substituting this value of l, the equation becomes

$$\frac{\cdot8\text{KC}}{x\text{D}} + \frac{\cdot112m\text{D}^2\text{C}}{x} + \frac{6\cdot4a\text{K}}{m\text{D}y} + \frac{1\cdot79a\text{D}^2}{y}.$$

If W is to be a minimum, then

$$\frac{d\text{W}}{d\text{D}} = o = -\frac{\cdot8\text{KC}}{x\text{D}^2} + \frac{\cdot224m\text{DC}}{x} - \frac{6\cdot4a\text{K}}{m\text{D}^2y} + \frac{3\cdot58a\text{D}}{y}$$

$$\text{D}^3 = \frac{\frac{\cdot8\text{KC}}{x} + \frac{6\cdot4a\text{K}}{my}}{\frac{\cdot224m\text{C}}{x} + \frac{3\cdot58a}{y}}$$

For a single-limb machine the equation becomes

$$\text{W} = \frac{(2l + \cdot7\text{D})\,m\text{D}\,\frac{\text{C}}{2} \times \cdot32}{x} + \frac{(2l + 1\cdot96\text{D})\,a\text{D} \times \cdot32 \times 2}{y}$$

or

$$\text{D}^3 = \frac{\frac{\cdot8\text{KC}}{x} + \frac{3\cdot2a\text{K}}{my}}{\frac{\cdot224m\text{C}}{x} + \frac{2\cdot5a}{y}}$$

The equation to give least weight of copper on the armature is

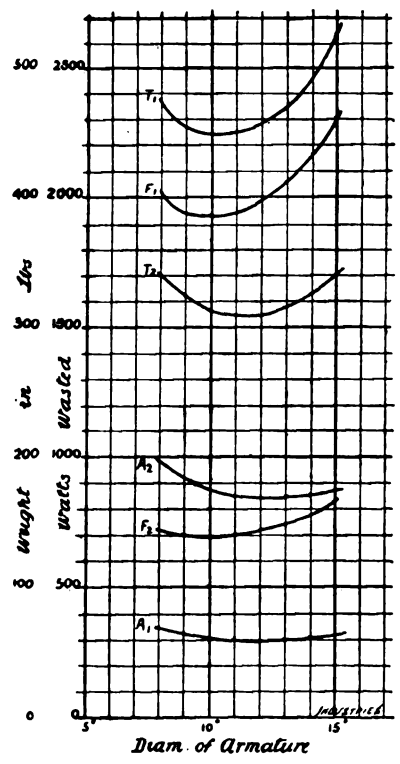
Digitized by Google

$$-\frac{\cdot 8KC}{xD^2}+\frac{\cdot 224mDC}{x}=0$$

$$D^3=\frac{3\cdot 56K}{m}$$

Substituting $\cdot 4lmD^2$ for K in this last equation gives $D = 1\cdot 43l$.

Taking as an example a machine to do $\frac{110\times 220}{1{,}000}$



Let current density in armature = 2,500
" " field = 900

$m = 13$; $a = 650$; $\beta = 96{,}000$; then K = 7,200. Then for a double-limb machine $D = 10\cdot 3$, $l = 13$; for a single-limb machine $D = 9\cdot 55$, $l = 15$; while the diameter to give least weight of copper on the armature is 12·55, and corresponding length = 8·75.

The following table gives the weights of copper on the armature and field of the double-limb machine, as given by the formulæ; they are also shown on the curves, A_1, F_1, T_1:—

Diameter.	Weight. Arm.	Weight. Field.	Total. Weight.
8in. ...	71lb. ...	403lb. ...	474lb.
9in. ...	66lb. ...	389lb. ...	455lb.
10in. ...	63lb. ...	385lb. ...	448lb.
11in. ...	61·5lb. ...	388lb. ...	449·5lb.
12in. ...	60lb. ...	399lb. ...	459lb.
13in. ...	60lb. ...	414lb. ...	474lb.
14in. ...	61lb. ...	434lb. ...	495lb.
15in. ...	62·5lb. ...	461lb. ...	523·5lb.

The proportion of length to diameter to give least weight of copper on the armature is independent of the output, current density, and number of turns; but as the diameter to give least weight on the armature is not the same as to give least weight on the field, the ratio of length to diameter for least total weight will vary slightly if the relative weight on the armature and

field is changed—that is, if the ratio of current densities or ampere turns on the armature and field is changed; but the ratio D/l will remain nearly the same as that found above—namely, ·77 for double limb and ·64 for single limb—for any variations of current densities and ampere turns within practical limits.

The assumption made above, that the ampere turns on the field vary directly as the diameter of the disc is not strictly accurate; in practice the ampere turns do not usually increase as fast as the diameter of the disc, so that the formula gives a diameter rather too small. If the current density is fixed, the watts wasted are proportional to the weight of copper, so that the diameter which gives least weight of copper on the armature also gives least watts wasted in the armature, and the diameter which gives least copper on the field gives least watts wasted in the field; but, as the current densities in the armature and field are not the same, the diameter for least total weight of copper does not coincide with diameter for least watts wasted. The watts wasted in any copper circuit of uniform current density, if the weight is known, may be found from the formula—Watts = $(\text{c.d.})^2 \times W \times 2\cdot 22 \times 10^{-6}$, where c.d. = current density and W = weight in lbs. This assumes that the copper is at the normal temperature, 60° Fahr.; if the temperature rises the coefficient, 2·22, must be increased in proportion to the increase of resistance. The following table gives the watts wasted in armature and field in the double-limb machine taken as example above:—

Diameter.	Watts. Arm.	Watts. Field.	Watts. Total.
8in. ...	982 ...	723 ...	1,705
9in. ...	918 ...	700 ...	1,618
10in. ...	872 ...	692 ...	1,564
11in. ...	852 ...	698 ...	1,550
12in. ...	832 ...	718 ...	1,550
13in. ...	832 ...	745 ...	1,577
14in. ...	848 ...	780 ...	1,628
15in. ...	868 ...	830 ...	1,698

The curves A_2, F_2, and T_2 show the variation of watts wasted with diameter of armature.

But the way the problem presents itself usually to the dynamo manufacturer is: Given certain stock sizes of discs, find which it is best to use for a given output. The weight of iron must also be considered, as the diameter for least weight of copper is not the same as diameter for least weight of iron in the field. The weight of iron in the armature core for a given output is independent of the diameter if β is constant. If copper costs ten times as much as iron, then the weight of iron in the field may be expressed in copper by dividing by 10. The best way to treat this problem is to select three most likely sizes of discs, and work out the weight of copper on each, including weight of copper equivalent to iron in the field.

Take as an example a machine to do the same output as before, $\frac{110\times 220}{1{,}000}$. Let the stock sizes of discs be 10in., 12in., and 15in. For a double-limb machine the section of iron in the field will be $2\cdot 8l$, $3\cdot 36l$, and $4\cdot 2l$ respectively. Then let the lengths of iron in the magnets of this section be 72in., 78in., and 88in. respectively, the turns on the armature 130, 156, and 204; the A.T. on each former 6,500, 7,500, and 9,300—

$$\text{Then}\quad W=\frac{\left(\frac{2K}{\cdot 4nD}+\cdot 7D\right)n\times\frac{C}{2}\times\cdot 32}{x}+$$

$$\frac{\left(\frac{2K}{\cdot 4nD}+1\cdot 4D\right)(AT)\times\cdot 32\times 4}{y}+\frac{\cdot 28DK\times 72\times\cdot 28}{\cdot 4nD\times 10}.$$

For 10in. diameter this becomes

$$W=\frac{\left(\frac{K}{2\times 130}+7\right)130\times 110\times\cdot 32}{2{,}500}+$$

$$\frac{\left(\frac{K}{2\times 130}+14\right)6{,}500\times 1\cdot 28}{900}+\frac{2\cdot 8K\times 72\times\cdot 28}{4\times 130\times 10}=$$

$$63+386+78=527\text{lb.}$$

For 12in.,

$$W=\frac{\left(\frac{K}{\cdot 2\times 156\times 12}+\cdot 7\times 12\right)156\times 110\times\cdot 32}{2{,}500}+$$

$$\frac{\left(\frac{K}{\cdot 2\times 156\times 12}+1\cdot 4\times 12\right)7{,}500\times 1\cdot 28}{900}+$$

$$\frac{3\cdot 36K\times 78\times\cdot 28}{\cdot 4\times 156\times 12\times 10}=60+377+70=507.$$

For 15in.,

$$W=\frac{\left(\frac{K}{\cdot 2\times 204\times 15}+\cdot 7\times 15\right)204\times 110\times\cdot 32}{2{,}500}+$$

$$\frac{\left(\frac{K}{\cdot 2\times 204\times 15}+1\cdot 4\times 15\right)9{,}300\times 1\cdot 28}{900}+$$

$$\frac{4\cdot 2K\times 88\times\cdot 28}{\cdot 4\times 204\times 15\times 10}=63+430+60=553.$$

This shows that the 12in. machine will cost least in material, in armature, and field, though the 15in. is the lightest machine.

THE PHYSICAL SOCIETY.

At a meeting of this Society on the 12th inst., Professor W. G. Adams being in the chair, Professor Ayrton read a paper on "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power," by himself and Dr. Sumpner. In a paper read before the Society in March last, the authors pointed out that for every method of measuring power in which readings of volts and amperes were taken, other methods in which amperes were read instead of volts, and volts

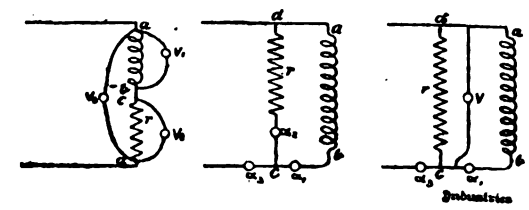


Fig. 1. Fig. 2. Fig. 3.

the non-inductive resistance r is measured by the aid of a voltmeter V across its terminals. This obviates the necessity of putting an electromagnetic instrument in what should be a non-inductive circuit. The formula for the mean watts spent in the circuit a b, Figs. 1 and 2, are respectively—

$W = 1/2r\,(V_3^2 - V^2 - V_2^2)$ and $W = r/2\,(A_3^2 - A_1^2 - A_2^2)$.

Mr. Blakesley's method of measuring power by a split dynamometer was shown to be analogous to the original electrometer method in which the difference of two readings was proportional to the power, and Blondlot and Currie's double electrometer method was shown to be the analogue of the ordinary wattmeter. The wattmeter was defective in the fact that a solenoidal coil was inserted in a nominally non-inductive circuit. The error thus introduced is, as was shown by one of the authors some years ago, expressed by the formula—

$$\frac{\text{apparent watts}}{\text{true watts}}=\frac{1+\tan\theta\tan\phi}{1+\tan^2\phi},$$

where θ is the phase angle between the current and e.m.f. in the circuit in which the power is to be measured, and ϕ the phase angle for the approximately non-inductive circuit. It is now proved that the same formula expresses the error in any of the methods where resistances not wholly non-inductive are used. As is well known, Mr. Blakesley has applied his split dynamometer to the measurement of phase differences between two currents, and an analogous method of finding the phase difference between two potential differences is described in the paper. In this method a high-resistance split dynamometer, such as suggested by Mr. Rimington for measuring power, is employed. Blondlot and Currie's double electrometer could also be used for the same purpose.

Professor S. P. Thompson inquired whether hot-wire voltmeters could be employed to measure the various potential differences without introducing error. In reply, Professor Ayrton said that, although no great error was introduced by the self-induction of these instruments, yet the fact that they required considerable current was a disadvantage, and as these currents were not always in the same phase as those in other circuits, troublesome corrections were sometimes necessary. Electrostatic instruments were preferable.

Professor Adams said he was glad to hear that the inductance of Cardew voltmeters introduced no serious error, for they were very convenient instruments to use.

Professor O. Lodge exhibited and described "A Clock for Pointing Out the Direction of the Earth's Orbital Motion in the Ether." After mentioning the various motions to which a point on the earth's surface is subjected, he pointed out that the orbital motion was the largest component, and its direction at any instant not easy to conceive. An apparatus for pointing out this direction was, therefore, convenient when dealing with problems requiring a knowledge of the motion of a point through the ether. In one of two clocks shown, one spindle representing the earth's polar axis and another the axis of the ecliptic were inclined at an angle of $23\frac{1}{2}$ degrees and coupled by a Hooke's joint. The latter axis was capable of rotating round the former. At its upper end the ecliptic axis carried a tube and a pointer, both being perpendicular to the axis and to each other. The clock keeping solar time rotated both axes, and when properly set the tube pointed in the direction of the sun, and the pointer, therefore, indicated the direction of the earth's orbital motion.

"Some Experiments with Leyden Jars" were then shown by Professor Lodge. The first one was with resonant jars, in which the discharge of one jar precipitated the overflow of another when the lengths of the jar circuits were properly adjusted or tuned. The latter jar was entirely disconnected from the former and was influenced merely by electromagnetic waves emanating from the discharging circuit. Lengthening or shorten-

Digitized by Google

ing either circuit prevented the overflow. Correct tuning was, he said, of great importance in these experiments, for a dozen or more oscillations occurred before the discharge ceased. The effect could be shown over considerable distances. In connection with this subject Mr. Blakesley had called his attention to an observation made by Priestly many years ago, who noticed that when several jars were being charged from the same prime conductor, if one of them discharged, the others would sometimes also discharge, although they were not fully charged. This he thought might be due to the same kind of influence which he had just shown to exist. The word "resonance," he said, was often misunderstood by supposing it always had reference to sound, and as substitutes he thought that "symphoning" or "symphonic" might be allowable.

The next experiment was to show that wires might be tuned to respond to the oscillation of a jar discharge just as a string could be tuned to respond to a tuning fork. A thin stretched wire was connected to the knob of a jar and another parallel one to its outer coating, and by varying the length of an independent discharging circuit a glow was caused to appear along the remote halves of the stretched wires at each discharge. Each of the wires thus acted like a stopped organ pipe, the remote ends being the nodes at which the variations of pressure are greatest. By using long wires he had observed a glow on portions of them, with the intermediate parts dark. This corresponded with the first harmonic, and by measuring the distance between two nodes he had determined the wave length of the oscillations. The length so found did not agree very closely with the calculated length, and the discrepancy he thought was due to the specific inductive capacity of the glass not being the same for such rapidly alternating pressures as for steady ones. He also showed that the electric pulses passing along a wire could be caused (by tuning) to react on the jar to which it was connected, and cause it to overflow even when the distance from the outside to the inside coating was about 8in. During this experiment he pointed out that the noise of the spark was greatly reduced by increasing the length of the discharging circuit. The same fact was also illustrated by causing two jars to discharge into each other, spark gaps being put both between their inner and outer coatings, so as to obtain "A" sparks and "B" sparks. By putting on a long "alternative path" as a shunt to the B spark gap, and increasing that gap, the noise of the A spark was greatly reduced. He had reason to believe that the B spark was a quarter phase behind the A spark, but the experimental proof had not been completed.

He next described some experiments on the screening of electromagnetic radiation, in which a Hertz resonator was surrounded by different materials. He had found no trace of opacity in insulators, but the thinnest film of metal procurable completely screened the resonator. Cardboard rubbed with plumbago also acted like a nearly perfect screen. In connection with resonators, he exhibited what he called a "graduated electric eye," or an electric harp, made by his assistant, Mr. Robinson, in which strips of tin foil of different lengths are attached to a glass plate, and have spark gaps at each end which separate them from other pieces of foil. One or other of the strips would respond according to the frequency of the electromagnetic radiation falling upon it.

Mr. Blakesley asked whether the tuning of the resonant jars needed readjustment when the distance between their circuits was varied, for, according to theory, the mutual induction should diminish the self-induction of the primary, and cause its oscillations to be more rapid. If this was true, the method might be used for getting rapid oscillations. He also inquired whether the glow would appear in the same position on the two stretched wires if their ends were joined.

Dr. Sumpner wished to know how the resistances, inductances, and capacities of the circuits and jars were determined, and whether any evidence of irregular distribution of the charges on the tin foil had been noted. With reference to the overflowing of a jar caused by using a certain length of discharging circuit, he asked whether the overflow did not prove the existence of a higher potential than that which originally existed between the coatings of the jar, and, if so, where did the excess energy come from?

Dr. Thompson asked if it would be possible to make a wire circuit analogous to an open organ pipe by putting sheets of metal on the ends of the wires.

Dr. Lodge, in reply, said Mr. Blakesley's suggestion was an important one, but he had not observed that any change in the adjustment was necessitated by varying the distance between the resonating circuits. Neither had he noticed any glow on wires joined to form a single loop, but this might be possible if the wires were long enough to give harmonics. In answer to Dr. Sumpner, he said that the capacities were difficult to determine, for with such rapid oscillations the coatings were virtually enlarged. Lord Rayleigh had shown how to calculate the inductances, and the resistances he had practically measured by his alternative path experiments. The overflow of jars, he thought, was caused by the charges in some way concentrating on the edges of the foil, thus causing a kind of flood tide at which the overflow occurred.

The President asked Dr. Lodge what his views were as to the cause of the opacity of ebonite to light. Was it due to a selective absorption, which cut off only the rays to which the eye was sensitive, or was the ordinary explanation that it contained impurities which were conducting, and hence acted as screens, likely to be correct? Another possible explanation was that the motion of the ether particles may be in three dimensions, and light be due to the projection of this motion on a plane perpendicular to the ray, whilst electromagnetic induction might be due to the other component. Dr. Lodge said he believed that ebonite was not opaque because of conducting particles being present, and was inclined to think that it acted more like ground glass, in which the opacity was due to internal reflections. Such a substance would only be opaque to vibrations whose wave length were comparable with the size of the particles.

A note "On the Construction of Non-inductive Resistances," by Professor W. E. Ayrton, F.R.S., and Mr. T. Mather, was postponed until next meeting.

SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

The last meeting of the session was held on the 19th inst., when a paper was read by Mr. R. Le Neve Foster, entitled "Chemical Manufacturers and Smoke." The author said he wished to bring under discussion the present state of the law with respect to smoke, as chemical manufacturers in East Manchester were being much harassed by the municipal authorities. The cotton industry was predominant in and around Manchester, and where this industry existed it was highly important that all the chemicals used by the bleacher, dyer, and calico printer should be produced in the same locality. It must, therefore, be concluded that chemical works in that neighbourhood were a necessity, but although most people were under the impression that they must necessarily be injurious and noxious, he asserted that the majority of these works were conducted with a great amount of care. Inasmuch as they provided a means of employment for the population, they were a blessing rather than a curse to the neighbourhood in which they were situated. Chemical works had recently been attacked for the emission of black smoke, and, as chairman of the newly formed Chemical Manufacturers' Association, he had, therefore, represented to the city authorities the special conditions under which these works had to be carried on. But although he had been led to expect otherwise, no attention had been paid to his suggestions. The Association did not view the smoke question in any spirit of antagonism to the Corporation or to the Noxious Vapours Abatement Association, but wished to compel its members to do all in their power to minimise the emission of smoke. All manufacturers who wished to join the Association were obliged to prove that they had adopted the best known means of consuming their smoke consistent with the effective carrying on of their works. It was, he believed, maintained by the city authorities, that no matter how perfect their furnaces were, still, if black smoke was emitted, the saving clauses of the smoke section of the Public Health Act, 1875, did not apply. This view had recently been upheld by the Court of Appeal, but, if legally correct, it was neither an equitable nor a commonsense rendering of what was evidently intended. To his mind the evident intention of the Legislature was to protect works of such a nature as made the consumption of smoke impracticable. They all knew that in chemical works it was impossible at times to prevent the emission of black smoke, and that manufacturers could not comply with the regulation of the smoke inspectors that black smoke should not issue for a longer period than one minute in each half-hour. Intermittent firing, as in the case of retorts, cylinders, pots, and stills, could not possibly be done in such a smokeless manner as the firing of an ordinary steam boiler. This was what the Legislature had in view when the saving clause to section 91, sub-section 7, of the Public Health Act was introduced. If a prosecution could be maintained simply for the emission of black smoke, without regard to the nature of the manufacture, the conclusion was evident that the majority of the chemical works must be closed and these industries be transferred to other countries. With regard to the inspectors' standards, he maintained that the true criterion was the quantity of smoke in relation to the coal consumed. It was not to the personal advantage of any manufacturer to create a nuisance. Moreover, it was a remarkable fact that the district where the bulk of the works were situated had the lowest death-rate in the neighbourhood, and this proved that smoke abatement was of less vital importance than other sanitary reforms. In conclusion, he would urge upon the Corporation the necessity of treating chemical manufactures in the spirit evidently intended by the Legislature, by applying the saving clause to section 91, sub-section 7, of the Public Health Act, 1875, with respect to the emission of smoke.

A somewhat lengthy discussion followed, all the speakers agreeing with Mr. Foster in condemning the smoke prosecutions.

Mr. Grimshaw said that where such a large quantity of coal was burnt as was the case in Manchester, a certain amount of smoke must necessarily be produced. He believed that it would very shortly be proved to demonstration that factories were not the chief producers of black smoke.

Dr. Dreyfus read abstracts from notes he had prepared, and showed that, if not one of the pleasantest, the neighbourhood of chemical works was one of the healthiest places to live in. In the course of his remarks he contended that in the case of the rectification of oil of vitriol in glass pans it was impossible to prevent smoke, as one man had to look after so many small fires. The harmfulness of smoke was not to be judged by the colour, as grey smoke was really more deleterious.

Mr. W. Thomson, who followed, supported this last statement with some figures, showing the oily nature of household as compared with factory smoke.

Dr. Bailey contended that competent men should be appointed as inspectors, who would be able to report whether the emission of smoke was preventible or not. Such Acts as this and the Rivers Pollution Act were failures because they treated all trades and manufactures under the same provisions.

Mr. Davis said that he believed tall chimneys would eventually be done away with, and the injurious smoke disseminated close to the ground. This could be done by the employment of forced draught. He had proved that it was the sulphurous acid, and not the carbon, in smoke which was injurious to vegetable life, by first burning benzene and afterwards coal in a greenhouse. The solution of the smoke question was to be looked for in the use of gas, but gas could not be economically used at its present price.

Dr. Simpson, M.D., said he had been disappointed with the tone of Mr. Foster's paper, and thought that both Mr. Foster and the subsequent speakers had merely been making an elaborate apology for the production of smoke and the perpetuation of nuisances. He did not think that the enormous advance made in practical chemistry and its application to arts and manufactures should be allowed to remain without effect in diminishing the nuisances which certainly existed. The comparison of the death-rates of different districts was fallacious, as a great many factors were involved, and the manufacturers had that evening admitted that their tall chimneys carried away the smoke to other parts.

Mr. Foster, in his reply, said that Dr. Simpson was wrong in thinking that manufacturers had done nothing to abate the smoke nuisance. He had also proved, he said, that all the black smoke emitted from his works fell within a distance of a quarter of a mile.

THE WHISKY INDUSTRY.

Some important information and opinions have been brought forward in connection with the sittings of the recent Select Committee on Spirits. The whole question is interesting from many points of view. The production of the various commercial forms of alcohol is one of the great industries of the British Isles, and gives employment in districts where other manufacturing enterprises do not flourish. Whisky, using this term to include all spirit distilled from grain, is the product that most of all concerns the inhabitants of our islands, for although brandy, the spirit from wine, is consumed to some extent, the whole quantity imported—less than three million (proof) gallons per annum—is inconsiderable in comparison with the forty-one million gallons of spirit, produced mostly from grain, which is made in this country. The question, What is whisky? is, however, not easily answered. Every one knows that alcohol results from the life action of yeast upon certain saccharine matters in aqueous solution, and, of all forms of saccharine, only three are utilised in commercial fermentations. Brandy is derived from glucose, the natural sugar contained in grapes, and rum is prepared from sucrose, the sweet substance elaborated by the sugar cane. With these we have no concern at present, except to say that much of the brandy sold is free from suspicion of the vine, and that some rum is innocent of connection with the sunny lands where the cane flourishes. Whisky is made from starch, which properly should be the starch of grain.

Digitized by Google

Some persons go so far as to say that the grain should be barley, but so strict a definition would exclude the large quantity of spirit distilled partially or wholly from oats, rice, rye, or maize, to which the term whisky is applied. When these various grains are allowed to commence germination, the albumenoid substances contained in the seed are partially converted into diastase, which has the curious property of causing starch to pass into a mixture of dextrin and maltose. The former term includes a number of bodies, but the latter is definite, and represents a sugar which, like cane sugar and glucose, is capable of being changed by yeast into ethylic alcohol. After the germination of the grain has proceeded to the requisite extent, the vital change is arrested by drying, and the result is malt. This is placed in contact with water between certain ranges of temperature in order that maltose may be produced. But the amount of diastase in malt is more than sufficient to "convert" the starch associated with it, and it is therefore the practice with many distillers to mix with the ground malt a quantity of raw grain, the starch of which is also changed into saccharine by the excess of diastase. Whisky, *par excellence*, is spirit obtained by the use of malt alone, and this is admitted to be superior to that which results when raw grain is introduced into the mash tun. There are in the United Kingdom 115 distillers using malt only, and of these 113 are in Scotland, the remaining two being in Ireland, where the use of mixed materials is the general custom. The quality of the spirit, however, depends not only upon the nature of the materials, but upon the form of apparatus used in distillation. The reason for this becomes apparent upon consideration of the chemical nature of the process of fermentation. Ethylic or common alcohol is the main result of this action, but accompanying it in small quantity are other alcohols and certain ethers, collectively known as fusel oil, and to the presence of these the odour and flavour of commercial spirits are due. These bodies come over with the ethylic alcohol from the pot still, but are almost entirely separated from the distillate when what is known as the "patent still" is employed. This form of still, regarded as a piece of scientific apparatus, is almost perfect, but the pure alcohol it produces, being practically devoid of fusel oil, is tasteless and insipid, and cannot justly receive the name of whisky.

It may surprise some who have been accustomed to hear fusel oil spoken of as a deadly poison, to be told that, on the contrary, this composite substance is, as it were, the "soul" of whisky and other spirits; and that it is scarcely to be regarded as hurtful—at all events in the proportions in which it usually exists—yet such appears to be the case according to Mr. A. H. Allen, who was a prominent witness before the recent Commission, and is one of the highest authorities on this subject. In a paper lately read before the Society of Chemical Industry, he stated that the whole theory of the banefulness of fusel oil was "trumped up about the year 1," and that people have gone on believing the statements without a jot or tittle of supporting evidence. In order to give point to a pronouncement so startling, Mr. Allen took every evening for some time part of a sample of whisky, to which was added 2 per cent. of fusel oil. The whisky, it appears, was nauseous, but its use occasioned not even the inconvenience of a headache on any occasion. This experience may be taken as disposing of the previous views, especially when it is added that experiments made by Mr. Samuels, Chief Chemist to the Inland Revenue, gave similar results. The ordinary mind, relying on the adage—that what does not poison must fatten—will doubtless require further information as to the function of fusel oil, and will be confronted with serious differences of opinion. Mr. Allen and the majority of chemists express the view that fusel oil, during the storage of whisky, becomes partially converted by oxidation into a number of desirable ethers, which impart to the matured spirit the mellowness, fragrance, and stimulating properties characteristic of old as against new whisky. Improved methods of analysis, described for the first time in the paper referred to, have made possible a discrimination between the unoxidised higher alcohols of fusel oil and the ethers also present, even from the first, and the facts and figures put forward certainly strongly support the views of those who hold the oxidation theory. Analyses of old whisky show a higher ratio of ethereal-ised—that is, oxidised—constituents of fusel oil, and the same is true of spirit prepared wholly from malt in comparison with that made from a mixture. More extensive and more systematic experiments with the new methods, however, are desirable, and such might fittingly be undertaken by a committee of chemists, working under the auspices of the whisky trade, upon larger quantities of material furnished in duty-free condition by the Excise Department of Her Majesty's Inland Revenue. The opinions of Dr. Bell, of Somerset House, are not quite in accordance with the views of Mr. Allen and those who agree with him. This chemist ascribes the ill flavour of new spirits to the presence of empyreumatic or cresotic bodies derived from partial charring of the materials in the still, and considers the admitted improvement brought about by storage in cask to be due to the removal of such substances, or their conversion into other forms. We await with much interest the further development of Dr. Bell's hypothesis, which, up to the present, can only be regarded as slender and unsupported by published facts. Possibly the two causes combined, and others, including the demonstrated influence of the oak of the cask, may all tend in the one direction of improvement, but this, however, is clear—that old whisky is better than new, being more stimulating without being more intoxicating, and pleasanter to drink. Those whose taste is for whisky, and whose pocket enables them to seek for the best, irrespective of price, may in the meantime be advised with confidence to choose a spirit made entirely from malt, and mellowed by the only legitimate method—namely, storage for several years in wood.

Notes.

ELECTRIC LIGHTING AND THE TEMPERATURE OF FACTORIES.

THE use of electric lighting in factories is evidently going to effect a great improvement in the ventilation of factories, as well as a considerable reduction of the temperature of their atmosphere. From a report by Mr. Beaumont, H.M. Inspector of Factories for Bradford, we learn that he has procured data for a comparison of the temperature in a wool-combing shed when lighted by electricity and by gas from 7 p.m. till 6 a.m. With gas the temperature rose to 109° Fahr. by midnight, while with the electric light it never rose above 96°.

ELECTRIC RAILWAYS.

IT is estimated that there are not less than 325 electric railways in the United States, England, Germany, Italy, Australia and Japan, requiring over 4,000 cars and 7,000 motors, with 2,600 miles of track, with a daily mileage of not less than 400,000 miles, and carrying 750,000,000 passengers annually. Grades of 13 and 14 per cent., distances of six miles or more from the central stations, speeds as high as from twenty-five to thirty miles per hour for single cars and trains of from two to four cars, are, according to the *Western Electrician*, features of their operation. Not less than 10,000 persons represent the number employed on these lines. Fifty millions of capital invested in the United States alone, and a present annual business not less than $8,000,000 to $10,000,000 on the part of the manufacturing and contracting electrical companies, show the present standing of the street railway works.

COAL SUPPLIES OF CALIFORNIA.

THE following table, showing how California is supplied with coal, is interesting as showing the development which is taking place in coal production in new countries, to which we have several times directed attention :—

	1888. Tons.	1889. Tons.	1890. Tons.
British Columbia	345,681	417,994	350,388
Australia.....	271,612	408,032	153,920
England and Wales	126,167	32,890	53,374
Scotland.....	10,680	12,727	1,490
Eastern States	38,118	18,950	32,701
Puget Sound	568,948	372,514	450,762

THE INDUSTRIES OF STETTIN.

THE chief industries of Stettin have only been developed to any large extent during the last fifteen or twenty years, but have in that time become many and important. Shipbuilding is very largely carried on, the banks of the deep River Oder presenting excellent facilities for the formation of docks and slips. Among the chief building yards may be mentioned those of the "Vulcan" Company, and Messrs. Müller and Holberg. There are no less than five companies engaged in the manufacture of Portland cement and other materials connected with building. A large paper and cellulose manufactory is situated near Alt-Damm, and another at Varzin. In consequence of the large cultivation of potatoes, large distilleries have been erected for the preparation of potato spirit, while sugar factories are very numerous. The soap and candle works give employment to nearly 300 men. In the district of Schlawe, 298 men are employed in the manufacture of matches. Oil mills for the extraction of oil from rape seed, cotton seed, and copra are situated near Stettin, last year's output amounting to about 30,000 tons; besides the various mills there are seven oil refineries. The manufacture of chicory is also of considerable importance. There are several large and important chemical works situated at or near Stettin. The Stettin steam flour mills are of very considerable dimensions; the amount of flour exported during 1889 was 734,700 tons, irrespective of the amount consumed in Stettin. There are several other smaller steam mills doing an equally good business in proportion to their size.

THE COLOURING MATTER OF ULTRAMARINE.

ULTRAMARINE has long been a chemical puzzle, alike in its constitution, the cause of its colour, and the vicissitudes of its manufacture, but now at least there is reason to suppose that one of these questions is in a fair way to be definitely solved. Some time ago it was suggested that the colour of ultramarine was due to the presence of an allotropic modification of the element sulphur, a substance capable of many vagaries. Mr. F. Krapp has recently pursued the former line of inquiry by investigating the so-called "black sulphur" of Magnus, which has hitherto figured in the text-books, and in them exclusively. He finds that "black sulphur" is not sulphur only, but a mixture of a certain modification of sulphur with a compound containing both sulphur and carbon. This modified form of sulphur by mere subdivision gives a blue colour to the substance used to subdivide it, and there appears to be little doubt that ultramarine simply consists of a basis of colourless silicates impregnated with blue sulphur resulting from the sodium sulphide formed in the ordinary course of manufacture. As blue sulphur in a state of isolation is unstable, and quickly passes into the yellow variety, it is easy to understand that on decomposing the colourless "base" by means of an acid the sulphur itself undergoes change, and ultramarine as a pigment ceases to exist. Mr. Krapp suggests that this same modified form of sulphur may play a part in the production of vulcanite, and that the blue colour of certain blast-furnace slags may be due to it. In any case sulphur which boils at a temperature far above 440° C., whose vapour is colourless, which oxidises to sulphur dioxide without visible combustion, and which itself is moreover blue, is a body sufficiently remarkable to warrant further research.

A NEW INSULATING MATERIAL.

A NEW insulating material bearing the name of Voltite has recently been introduced. It is composed (states the *India Rubber and Gutta Percha Trades Journal*) of a mixture of gelatine (specially made), resin oil, oxidised linseed oil, resin, and paraffin. It is cheap, and contains no sulphur. The proportions of the mixture are :—Glove glue (colle de gant), 1,000 parts; resin oil, 100 parts; oxidised linseed oil, 500 parts; colophane, 150 parts; paraffin, 250 parts. This glue is prepared by taking the refuse clippings of gloves and soaking them in cold water for one night. The next day they are strained and washed in several waters until the water is clear. In an iron boiler there are then placed 1,000 parts of water, 5 parts of carbonate of soda, and dry glove skin 250 parts. This is boiled for six consecutive hours, the water being renewed as it evaporates. The whole boiling mass is next run over a sieve, across which steam is passed to prevent the gelatine coagulating. The boiling solution is received by a wooden tub, through which a current of warm air is passed for one hour. The residue left in the sieve is boiled up with water for three hours, and, when filtered, can be used again for dissolving the glue, but this time with only 200 parts of glove skin. The gelatinous solution is put into a boiler with olein or oleic acid, used in candle manufacture, in the proportion of :—Gelatinous solution, 1,000 parts; olein, 80 parts. This is boiled for half an hour, after which 10 parts of caustic potash solution (50 parts water) is added. The boiling is maintained for an hour, so as to saponify the olein and form a soapy pulp. The glove glue being ready, resin oil, colophane, and paraffin are added, in the proportions above stated; the whole is boiled until homogeneous. This boiling generally lasts about four or five hours.

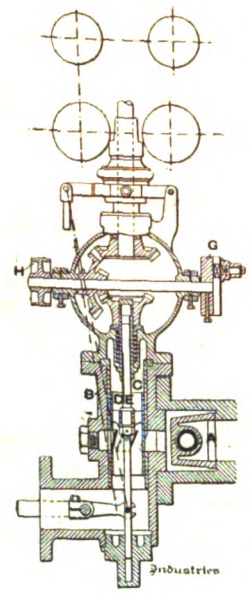
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

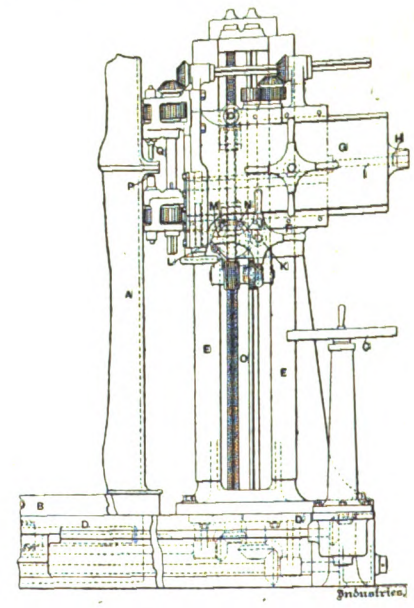


ENGINEERING.

Boiler Feeding Device.—*W. P. Thompson, Liverpool.* (*A. Kriener, Summi, Russia*).—This invention embraces a device for conveying the steam and condensation water from steam heated apparatus, direct back to the boiler producing the steam, without any other mechanical aids. In carrying out the invention as shown in the accompanying illustration, a pipe A is provided, which conducts the steam from the boiler B

into a steam chamber C, situated in the double bottom of the boiling down or steam heated apparatus D, where it condenses as it yields up its heat and trickles back through the said pipe A. By another arrangement the steam is conducted by means of pipes E out of the boiler B into a pipe coil or worm F, and between the double bottom on the apparatus H, and the condensed water returns to the boiler by means of exhaust pipes I. In the first arrangement it is, of course, necessary to have, in the boiler B and steam chamber C, an approximately equal pressure, and an approximately equal temperature must prevail the other apparatus, on the contrary, renders it possible for a lower pressure and temperature to exist in the pipe coil F and in the steam chamber G than in the boiler. The difference of pressure is, in fact, compensated for by means of the weight of the condensed water collected in the exhaust pipe I. The difference of pressure existing in the boiler B, and in the steam pipe F, or chamber G, will, in every case, equal the height of the column of condensed water in the exhaust pipes I (measured from the water level in the boiler). The result is that, in case a great difference of pressure is to be reached, the apparatus H and the boiler must be so arranged that a considerable fall exists between them. Claims: The devices herein described and shown for conveying condensed water from the steam heated apparatus back to the boiler generating the steam, whereby the condensed water may be returned to the boiler by the action of gravity alone.—No. 2966. February 18th, 1891. 6*d.*

Expansion Valves.—*W. P. Thompson, Liverpool.* (*G. Jalsoviczky, Budapest, Hungary.*)—The adjustable double-valve gear of steam engines, which are mostly regulated by the governor, enable variable quantities of steam to be used. Considerable friction, however, results between the two valves, which has the effect of impairing the exactness of adjustment and of reducing the sensitiveness of the governor. The governor expansion valve constructed according to this invention is designed to remove this disadvantage and effect the automatic distribution of the steam without offering excessive resistance to the governor. The accompanying illustration shows this invention, it being a



section of the apparatus:—A is the distribution valve, and on its valve-box a cast-iron cylinder B is secured, which has inserted in it a metal cylinder C, in which moves a cylindrical valve D, having four three-cornered openings in it, and corresponding with similar openings in the metallic cylinder C. The cylindrical valve is seated on the rod E in such a way that it not only revolves with it, but can also move longitudinally in the cylinder C by the action of the governor, and by suitable means provided. The distribution takes place by the revolution of the cylindrical valve, steam being admitted to the passage outside the metallic cylinder C, and through the holes in the valve D, as they correspond with the holes in the cylinder C, into its inside. In the example shown, as there are four openings, steam will be admitted four times for each revolution of the valve D, which corresponds to two double strokes of the piston. Accordingly the engine will make two revolutions to one of the cylindrical valve. The revolution of the crank of the engine is transmitted by means of bevel gear in the cast-iron case to the governor in such a way that this makes half as many revolutions as the crank. Motion is also transmitted from the distributing valve to a crank G, and to overcome the dead points of the crank a belt pulley H is provided. Claims: Improved apparatus for controlling the distribution of steam in steam engines, consisting of a distributing valve and a cylindrical valve, in which latter are openings to correspond with openings in a cylinder, in combination with the governor gearing as described.—No. 6097. April 9th, 1891. 6*d.*

Gun Mountings.—*T. English, Dartford, Kent.*—Carriages and mountings for quick-firing guns, which are arranged to be transportable on wheels, to be capable of being pivoted in position, and to be aimed and fired from the shoulder, are described in this specification. The trunnions of the gun are held in blocks that can slide parallel to the axis of the gun on a cradle, which also is trunnioned, and is mounted by a pivot or perch pin on the upper part of the carriage, and which is provided in front with a pair of hydraulic recoil cylinders, one on each side of the gun, and in the rear with a pair of springs of sufficient strength to advance the gun after recoil to the firing position. The carriage has a trail and a pair of wheels, so that the gun can be readily moved from place to place. When it is desired to use the gun in position it is run onwards until the axletree of the carriage comes vertically over a fixed base provided to receive a pivot in its centre. This pivot, by means of a lever, is slid down from the body of the carriage into the hole of the fixed base, and a ring that can revolve round the upper part of the base is shackled to the carriage, which can then be traversed round the base so as to point the gun in any direction. The gunner, having his shoulder against a shoulder-piece projecting from the rear of the gun, can traverse the latter through a limited arc on the upper pivot in a horizontal plane, and can swing the gun on the trunnions in a vertical plane. To relieve the shoulder-piece from downward strain when the gun recoils, a friction strap applied to the cradle (which strap is usually kept loose by a spring, but which becomes tightened as the gun recoils) is applied to a drum forming part of the top carriage, concentric with the cradle, and acts as a brake to impede the descent of the preponderating rear of the carriage. Claims: In combination with the transporting carriage of a quick-firing gun, a fixed base with racer for the carriage wheels, and with a pivot and ring, to which the carriage is shackled for working the gun; in combination with the recoil cradle of a quick-firing gun a brake strap attached thereto, and embracing a fixed brake drum on the mounting.—No. 6488. April 28th, 1890. 6*d.*

Rotary Pump.—*A. J. Boult, London.* (*A. Lambert, Lyon, France.*)—The object of this invention is to construct an improved rotary pump with movable rollers, which consists of a cylindrical main casing in which revolves a disc or plunger. This plunger is of smaller diameter than the body of the pump, whilst its width is greater than the internal width of the body, which, with the cover, are suitably recessed in parts to receive the plunger, which is arranged eccentrically to the body of the pump so that it comes into contact with the circumference thereof at a part situated between the inlet and the outlet, which part may be curved to fit a small arc of the plunger's surface. The plunger receives rotation from the exterior, and is provided with recesses arranged symmetrically around its periphery and intended for the reception of cylindrical rollers; these recesses extend only partly across the periphery of the disc, their length being equal to the interior width of the main body of the pump. The sides or cheeks of these recesses may be integral with the pump plunger, or may be formed of circular plates secured to the ends thereof, and the body and cover of the pump should be bored to such a depth as will allow the cheeks to fit into them exactly, for they then render tight the side joints between plunger and pump body, and increase the power of the pump. Claims: A rotary pump and intype described, in which the recessed plunger has side cheeks, and fits into circular depressions in the pump body, the rollers being of the same length as the general width of the pump body, whereby the suction and discharge orifices are separated by the combined action of the weight of the rollers, the pressure of the liquid, and centrifugal force.—No. 10502. July 7th, 1890. 8*d.*

Drilling Machine.—*G. Booth & G. Pickersgill, both of Halifax.*—The inventors describe a special construction of machine for drilling the holes in the flanges of boiler flue sections, when two of such are in position with the annular metal ring or washer between them. The holes are thus drilled with accuracy, and are also countersunk in the manner to be described. A half-front elevation of a machine is given, with two sections of boiler tube in position in readiness to be operated upon. The flues A whilst being drilled are fixed on a circular table B, fitted with a series of ordinary jaw chucks, which are moved simultaneously. The table is rotated by a hand-wheel C, the said table resting upon a suitable bed D. At each end of this bed is a vertical standard E, and upon each standard is an adjustable vertical slide or saddle F, which carries an adjustable horizontal slide G for adjusting the drills in position for drilling. An adjustable stop nut H is placed upon a screwed rod I attached to the slide F in order to lock it after adjustment. The slide F is adjustable by the handle J, operating the gearing K L, which in turn operates a bevel-wheel M, such bevel-wheel operating a bevel-wheel N which slides upon the grooved vertical screw O. The lower counter-sinking drills P are operated simultaneously, and the slides G on each of the vertical standards are operated in unison, being geared together by the horizontal shafting shown in the illustration by dotted lines. The rose bits for countersinking top and bottom edges of the holes are indicated at P and Q. Self-acting feed me-

chanism is fitted as shown, and each saddle is provided with a balance weight and chain, not shown. Claims: A drilling machine for drilling the flanges and washers of boiler flues in position and countersinking the holes at one operation; constructing the drill holders, slides, and bearings, in the manner described; operating the pair of drills and headstocks independently or simultaneously.—No. 4035. March 6th, 1891. 6*d.*

Square Hole Drilling Machines.—*H. Ainley, London.*—This invention has for its object various improvements on previous patents granted conjointly to the inventor and A. Oakes, in which a revolving cutter is controlled by a pair of templates or their equivalent, and so made to cut a hole of a form corresponding with that of the templates. In the present improvements the inventor, instead of giving a lateral movement to the cutter spindle while in rotation and controlled by the templates, suspends the cutter spindle from a fixed point, and while it is rotating gives it an oscillating motion by means of a template, whereby the cutter will describe a figure corresponding to the form of the template. Claims: The arrangement of machinery

Digitized by Google

as described, in which an oscillating rotating cutter spindle is used, controlled by a rotating slide, and a fixed template for cutting square or approximately square holes.—No. 10956. July 14th, 1890. 8*d*.

TWIST DRILLS.—*C. Van Haagen, Chester, Delaware, U.S.A.*—The invention has for its object the manufacture of twist or straight drills or reamers by forging, and is carried out by having two gripping and forging dies having a movement to and from each other, their internal surfaces being adapted to forge the outer circumference of the drill with the groove. The invention

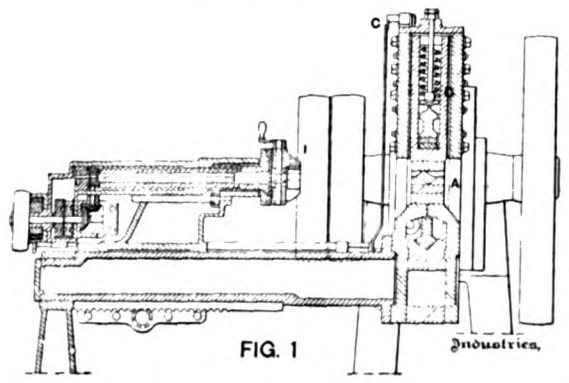


FIG. 1

also includes mechanism for reciprocating the dies and an automatic feed. This method, according to the inventor, leaves the tool with its outer skin almost untouched, and produces a tool of the greatest possible strength and durability. In the accompanying illustrations, which show the invention, Fig. 1 is a longitudinal section, Fig. 2 a front elevation with the feeding mechanism removed, and Fig. 3 a transverse section on the line Z Z (Fig. 2). A B shows the forging and gripping dies, the lower of which B is held in the main frame of the machine and the upper A is secured to a vertically reciprocating frame C operated by eccentrics and cams. D is the main shaft of the machine, and has two eccentrics E E secured upon it, which work two frames F F simultaneously in opposite directions, the frames being guided in the main frame of the machine, and holding two oppositely reciprocating hammer dies G G. One of the frames F has a cam engaging with a similar cam plate on the vertically reciprocating frame C, so that the reciprocations of the frame F cause the frame C to be projected downwards at each stroke. The frame C is returned by a spring H. A chuck I for holding the drill to be forged is carried by a frame which slides upon the main frame of the machine, and has arrangements to effect an automatic feed, so that at every one of the reciprocations of the

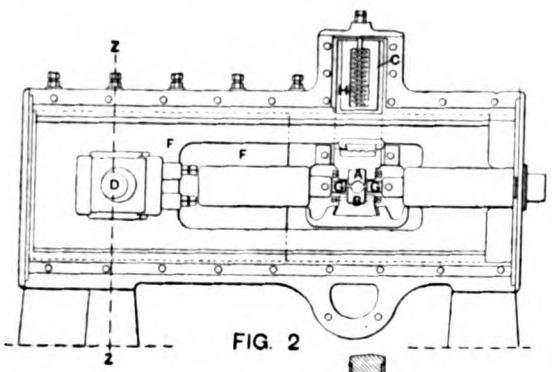

FIG. 2

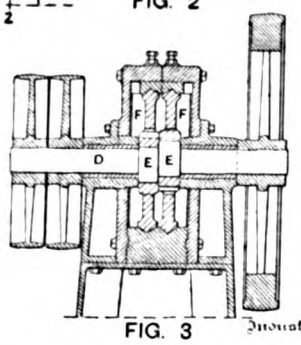

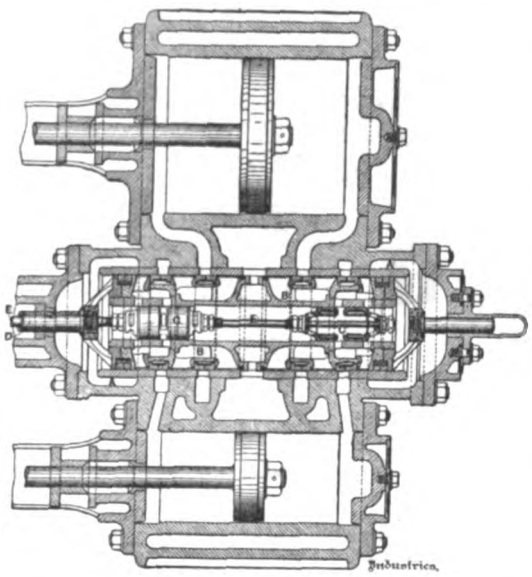

FIG. 3

frame C and its die there will be feeding movements communicated to the drill rod. There are sixteen claims to this specification, which claim the following main idea and its developments: In a machine for forging drills, the combination of reciprocating forging dies with a chuck to be moved to or from said dies, and mechanism whereby the movements of the dies or other operating parts control the movement of the chuck; in an automatic feeding apparatus as described, a brake to intermittently arrest the movement of the feeding device.—No. 15906. October 7th, 1890. 8*d*.

ANNEALING COPPER.—*T. W. Johnson, London.*—This invention relates to improvements in the method and apparatus for annealing copper wire and sheets, and has for its object to dispense with the tedious and expensive operation known as "pickling," which has had heretofore to be practised, in order to obtain a clean product after the annealing of the wire. This operation was necessary owing to imperfections attached to the annealing stage of the process. The process and apparatus for the treatment of copper wire are described; the same description would apply to the treatment of copper sheets except that the pot of particular form employed would be long, instead of circular. The copper wire having first been drawn to the required size, is first soaked in water to render it more pliable for winding purposes, and is afterwards drained and placed in layers, coils, or otherwise, in a specially arranged pot. This pot consists of three concentric pots, fitting closely one within the other, and the first or outer one of which is preferably of iron, while the other two are preferably of copper. Each pot has its own lid or cover, the last two lids having an upturned edge, whilst the first has a bent-down rim. The three pots, commencing with the outermost, are successively shorter. The wire is placed in the inner pot until it is filled, and the lid is placed thereon and luted around its outer periphery against the inner periphery of the intermediate pot. The luting is mixed white lead and putty, coated with red lead and oil. The intermediate pot is filled up with fine burnt wood dust, and its lid is placed on, a further quantity of the same filling going between this lid and the last or outer lid. The whole is heated and maintained at a red heat for about an hour. Claims: The process and apparatus described, and any mere modification thereof.—No. 4132. March 7th, 1891. 6*d*.

SLIDE VALVES.—*J. Marshall & R. Wigram, both of Leeds.*—The inventors have for their object the arrangement of slide valve and cylinder ports in such a manner as to control the supply to and discharge from a pair of cylinders arranged side by side and working either as compound or as twin cylinders. The accompanying illustration shows in longitudinal section a pair of cylinders constructed according to this invention. The metal between the two cylinders is bored out to receive a liner A, and has formed in it recesses communicating with ports leading to the ends of the two cylinders, and a larger recess in the middle for the exhaust. This liner A has a number of round holes drilled in it, facing the recesses previously described. Within the liner A is fitted the main slide valve B, which is tubular, and so shaped as to constitute a number of pistons, each being provided with spring packing; and within this slide valve B is a tubular expansion valve C. The slide rod D attached to the slide valve B is tubular, and has within it the slide rod E of the expansion valve C; these slide rods D and E may be worked by any suitable means, such, for example, as eccentrics or cams. The steam pipe being connected with either end of the steam

chest, charges with steam the two end parts of the chest and the middle part of the expansion valve C, from whence it will be admitted by ports in the expansion valve, and similar ones in the main slide valve, and the drilled openings in the liner into the respective ends of the cylinders, as will be readily understood on reference to the illustration. Claims: In combination with a pair of parallel cylinders and their ports, a cylindrical tubular slide valve, with packed piston parts governing passages to the said ports; the combination with the valve described of a tubular expansion valve arranged within the tubular slide valve.—No. 9300. June 16th, 1890. 6*d*.

CHANGE WHEELS.—*A. Eli, London.* (*L. Whiton, New London, Connecticut.*)—This invention has for its object the improvement of "back-gearing," such as is commonly used in lathes and like machines for increasing power. This "back-gear" has generally consisted of a shaft located in the rear of the cone spindle, and having gears that may be thrown into and out of mesh with the fixed and loose gears on said spindle. According to this invention the several elementary parts of such gearing are concealed within a cone which has the driving belt upon it. The specification describes two forms of this apparatus. The first, in which the change from fast to slow, or *vice versâ*, is effected quickly, and by one movement, while the machine is stopped; and in the second the change is effected while the apparatus is in motion. According to the first modification the headstock of the lathe has journaled in it a spindle, upon which a cone pulley is mounted, which, under certain conditions, may be connected to or disconnected from the spindle. To the spindle is secured a gear wheel, and to the journal is fixed by means of a thimble a smaller gear wheel. A spindle is secured within the cone, and has eccentrically mounted upon it connected gear wheels to gear with the two before-mentioned gear wheels, and also a locking device engaging with teeth on the spindle; so that if the engaging portions are turned into gear the pulley and spindle rotate as a whole, but when disengaged the motion is imparted through the gear wheels and so produces the increased speed. There are four claims, including the combination of a suitably journaled spindle, a pulley loosely fitted thereon, and a fixed gear with concentrically arranged fixed gear wheels journaled eccentrically upon an adjacent shaft, such gear wheels being arranged to be thrown in and out of mesh by the partial rotation of the eccentric journal.—No. 15058. September 23rd, 1890. 8*d*.

CUT-OFF GEAR.—*J. Lumb, Elland, York.*—From a reciprocating steady motion obtained by any suitable means, such, for example, as an eccentric, the inventor obtains two reciprocating motions timed alternately, and having a quick and free return for cutting off the steam. Attached to the valve rods are two sliding bars mounted in juxtaposition and free to move longitudinally. A space is left between the said bars, and on their adjacent faces a notch is formed having an inclined edge and a toothed or undercut edge. In the space between the two bars, two spring members of a trigger piece are caused to reciprocate longitudinally by the steady motion obtained from the engine as before mentioned. At the outer ends of the spring pieces are provided teeth to engage with the notches of the sliding bars. The operation is as follows:—At about the end of the outward stroke of the trigger piece, the tooth piece at the end of one of the spring pieces will engage with the notch on one of the sliding bars, and draw it back and open the valve. A suitable catch falls into position and retains the bar in that position, and the spring piece is disengaged from the notch. This causes the other spring piece to engage with the notch on the other sliding bar, pushing it forward, and so opening the other valve. This second bar is retained by another catch in its open position. Upon the second outward movement of the trigger piece the tooth of the first spring piece will again engage with the first-mentioned bar, which has in the meantime returned into its "closed" position by means of springs or the like. This invention is especially applicable to cut-off valves of the "Rider" class, and by means of a modification is equally applicable to such valves as the "Corliss," "stamper," "grid," "crown," "plug," and others. Claims: Connecting to the valve rods, sliding bars having notches, which notches engage with spring members, moving longitudinally with a trigger piece, for the purposes shown and described.—No. 11279. July 3rd, 1890. 8*d*.

VALVE GEAR.—*H. F. G. Meltzer, Charlottenburg, Germany.*—This is an apparatus for actuating the valves of steam engines which differs from other valve gear, in which it is claimed that the cut-off can be varied at pleasure within the widest limits, and without a reaction on the governor taking place, and all the periods of taking steam can be varied independently of each other. The accompanying illustrations show in Fig. 1 a side

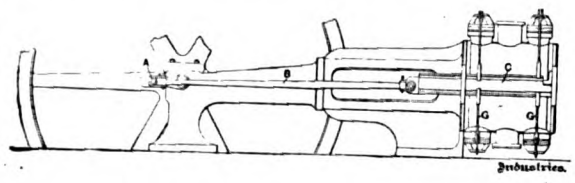

FIG. I.

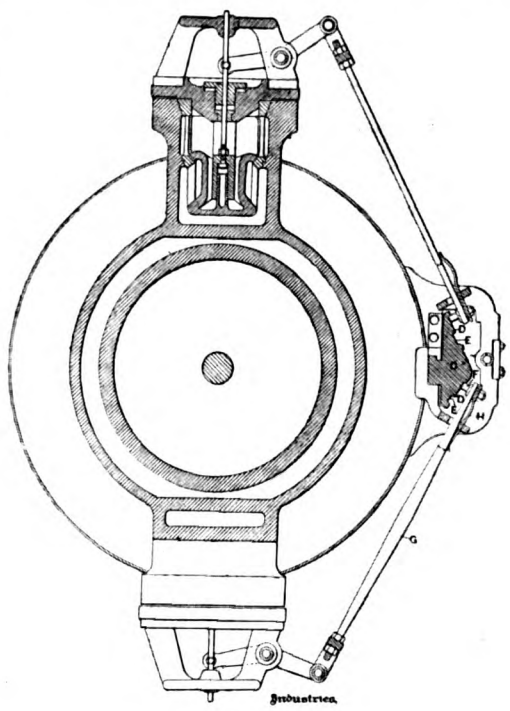
elevation of an engine fitted with this valve gear, and Fig. 2 a large section taken through the cylinder. The crank shaft of the engine has a crank pin A connected by a rod B with a slide C, which is free to travel in guides, and is so arranged as to be situated at the dead centre at the same time as the engine piston. This slide C is made to actuate the supply and exhaust valves, and the operation is as follows:—The slide C has two inclined surfaces (see Fig. 2), each provided with two grooves D and E, D being deeper than E. Into the one or other of these grooves a stud F, attached to the end of a rod G, engages. The slide C is prevented from shifting in a longitudinal direction to the cylinder by suitable guides, but is free to move in a direction transverse to the cylinder. A spring H bears on the end of the rod G, and forces the stud F into one or other of the grooves, and according to whether the stud F be in the upper or lower will depend whether the exhaust valves are open or closed. Inclines, not shown in the figures, are provided, which act on



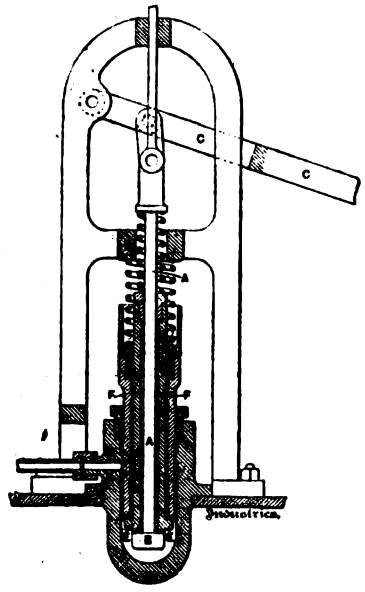


FIG. 2.

the stud F and force it up or down, and these are made adjustable. The adjustable inclined pieces are each attached to a rack, which racks are moved simultaneously in opposite directions by suitable gearing, or they may be automatically adjusted from the governor. Claims: Valve gear for steam engines, wherein rods that actuate the devices controlling the admission and discharge of the fluid pressure are provided, with studs which alternately gear with one or other of two grooves formed in a slide, which

Digitized by Google

travels longitudinally synchronously with the engine piston; the said studs being made to pass from one groove to the other by inclines brought into contact by the alternating motion of the slide, and so move the valve rods and alternately open and close the valves.—No. 8415. May 30th, 1890. 8*d.*

PUMPS.—*C. Kingsford, Erith, Kent.*—This invention is stated to be particularly applicable to pumps where the resistance increases as the work proceeds, as, for example, when raising the ram of a hydraulic press. The inventor employs several plungers, arranged concentrically and controlled by springs, so that, as the work increases, the effective area of the pump plunger is automatically diminished. The accompanying figure shows in vertical section a pressure pump constructed according to this in-

vention. A is the central plunger having a head or flange B and worked by means of the lever C. A second plunger D surrounds the plunger A, and also has a head or flange E. A third plunger F surrounds the plunger D. The plunger F is arranged to slide upon D, and the plunger D upon the central plunger A, and suitable packing is arranged between them. Two helical springs bear upon the tops of the plungers F and D. The action is as follows:—When the lever C is worked the three plungers A, D, and F begin to descend together. As the resistance of the pump increases the plunger F will be held back by the pressure, and the effective area will be only that of the flanges of the two plungers A and D. As the resistance increases still more, D will be held back by the pressure, and the plunger A will act alone. Any number of concentric plungers may be employed, and the inventor describes numerous modifications for carrying this invention into effect. Claims: The application of springs to give motion to plungers of large area while the pressure is comparatively low, which plungers cease to act when the pressure equals the resistance of the springs, a plunger of less area continuing the operation; the various modifications and appliances described are also claimed.—No. 7667. May 16th, 1890. 8*d.*

ELECTRICITY.

ELECTRIC RAILWAYS.—*J. Bayly, London.* (*T. Evans, San Francisco.*)—This invention relates to that class of electric railways which have a current collector attached to the motor car, making electrical connection with an insulated underground conductor. The improvements relate to the underground tube and to the construction of the current collector. The underground tube has a slot along the top, through which the shank or carrying bar of the collector is passed; on the top or roof of the underground tube and at one side of the slot the conductor is secured, and between the slot and conductor, and extending along the tube, a depending apron or partition is fixed. This apron, when carried down a suitable distance, protects the conductor from mud, water, and dust. The current collector is mounted on a suitably shaped trolly or support to enable it to pass over the apron, and consists of a grooved or double-flanged wheel or wheels, mounted in, but insulated from, the end of the support, with suitable binding posts provided by means of which wires enclosed within the support can connect the contact wheels with the motor. Claim: The combination with the stationary conductor of a trolly, having wheels mounted in insulated boxes, and binding posts, with electrical connection to the contact wheels.—No. 10252. July 2nd, 1890. 8*d.*

OVERHEAD CONDUCTORS.—*Siemens Bros. & Co., London.* (*Siemens & Halske, Berlin.*)—In overhead conductors for tramcars, &c., difficulty has been found in maintaining good electrical contact, owing to the vertical oscillation of the vehicle or varying height of the conductor. This invention has for its object the removal of these difficulties. This is carried into effect as follows:—Instead of supporting the arms carrying the sliding contacts on the vehicle body, a longitudinal horizontal bearer is mounted on but insulated from the axle boxes on one or both sides of the vehicle, and has attached to it the upright conducting arms carrying the sliding contacts. As the conducting arms project above the vehicle, they may be connected at the top by a rod or otherwise suitably braced together. The inventors prefer that the sliding contacts should be made to extend across the vehicle so as to be supported on each side by the conducting arms. Another arrangement described consists of making the supports, whether they be attached to the car body or axle boxes, as before described, with a yielding or spring action so that they automatically adjust themselves to the vertical vibrations of the carriage or to variations in the height of the conductor. This is preferably carried out by making the contacts with a hinge joint at any convenient point, and having a spring or counterweight to tend to bring the upper portion into a vertical position. Where several arms are used they may be so connected by horizontal arms that they will be deflected together in parallelogrammatic form. Claims: Mounting the contacts of electric railways working with overhead conductors upon supports carried by, but insulated from, the axle boxes of the vehicle, so that the contacts are independent of the vertical oscillations of the vehicle body; constructing the supports of contacts with hinged joints, and acting thereon with springs or the like tending to bring them always into a vertical position.—No. 10743. July 10th, 1890. 8*d.*

ARMATURES.—*B. D. Southard, Chicago, U.S.A.*—This invention relates more particularly to that class of armatures for dynamos and motors known as the "Gramme" or cylinder armatures, in which wire is wound longitudinally upon the outer surface of a cylindrical core, returning through the interior of the latter, until the entire surface of the armature is covered with wire. A series of wires from the commutator are connected to the coil in various parts, so as to divide the latter into several coils in series. Should one of these coils burn or otherwise break down, it is a matter of great difficulty to unwind the coil from the cylinder, and replace the injured coil, and this invention is designed to remove this objection by so modifying the structure of the armature that the destructible portions being of uniform size, and therefore interchangeable, may be in the event of a breakdown quickly applied even by unskilled persons. Referring to the accompanying illus-

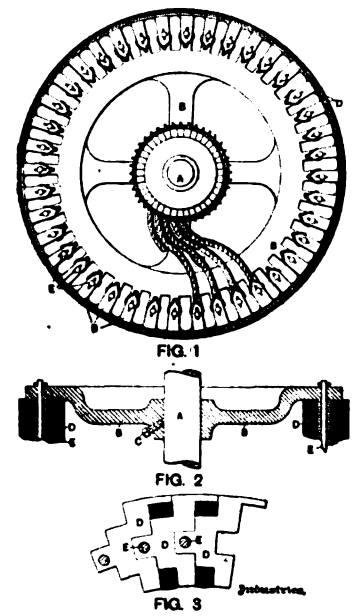

FIG. 1

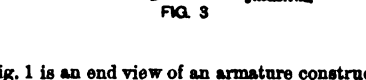

FIG. 2

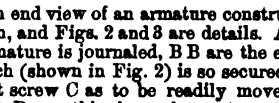

FIG. 3

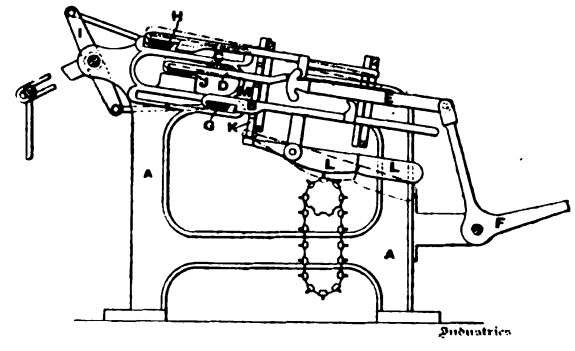
trations, Fig. 1 is an end view of an armature constructed according to this invention, and Figs. 2 and 3 are details. A is the shaft upon which the armature is journaled, B B are the end plates or spiders, one of which (shown in Fig. 2) is so secured or clamped to the shaft by a set screw C as to be readily moved longitudinally if required; D D are thin iron plates stamped out in the form shown in Fig. 3, and secured together by rods E E, which pass also through the spiders B B at each end. By the plates D D being of the form shown, with projecting pieces fitting into corresponding recesses, they form when placed together a continuous cylindrical armature, of which any portion with its coil may be readily removed, by unscrewing the nuts on the rods E, and moving the spider along the spindle. Certain modifications in the form of the plates D are described, as well as the application of this invention to disc armatures. Claims: In armatures of the class described, the combination of a series of independently removable sections, suitably connected together in the form of a cylindrical core, divided longitudinally by joints between the sections for the purpose described.—No. 5135. March 23rd, 1891. 8*d.*

CHEMISTRY.



CHLORINE.—*W. P. Thompson, London.* (*F. Marx, Berlin.*)—This invention has for its object the electro-chemical formation of chlorine and chlorine compounds, especially producing protochloride of iron and perchloride of iron in the cheapest way possible. By this invention metals, alkalies, and lyes are produced as direct bye-products, and caustic lime, chloride of lime, and salts as indirect bye-products. Chlorine is obtained, in accordance with this invention, by electrolysis of metallic chlorides, which can be of two kinds: (1) Electrolitic decomposition of watery solutions of the metallic chlorides. The main product of this is chlorine, and the bye-products are the hydrated oxides of alkaline earths, and other earths, and from the remaining metallic chlorides the metals as such. (2) Electrolytic decomposition of melted metallic chlorides, or mixtures thereof, or double combinations of the same. The main product is chlorine, and the bye-products are metals or metallic alloys. Negative carbon electrodes should be used in the decomposition of alkaline chloride combinations in watery solution, and negative metallic electrodes in the decomposition of melted metallic chlorides; and, when possible, they should be of the metal which is obtained as a bye-product of the decomposition. The apparatus consists of decomposing cells under which a heating apparatus is placed, and having tight-closing covers, each with a pipe for conveying the chlorine away, and means for electrical connection. Claims: The process described for the manufacture of iron protochloride, iron perchloride, and chloride of lime, in which chlorine gas produced by means of electrolytes formed of metallic chloride compounds, or of a mixture of the same, are employed for the dissolving of iron and for the saturation of hydrate of lime; in the process described, the obtaining of metals, lyes, and alkalies as bye-products.—No. 19942A. December 6th, 1890. 8*d.*

MISCELLANEOUS.

LOCK NUTS.—*H. E. Newton, London.* (*A. Gross, Sydney.*)—Ordinary bolts may be adapted to this method of locking a nut thereon. This is done by making a groove or key-way longitudinally in the screwed part of the bolt, and of sufficient depth to allow of a locking appliance or key to repose in it without interfering with the passage of the nut. The groove has an enlarged cavity at its end, which should be beyond the screwed part, and into this cavity the bulbous end of the locking appliance fits. After the nut has been screwed down the projecting portion of the locking piece is turned over the nut. Claim: The device for locking nuts on bolts, consisting of a key formed with an enlarged or bulbous end in combination with a corresponding groove formed in the bolt, the key being of sufficient length to enable it to be turned over the nut.—No. 6486. April 15th, 1891. 6*d.*

WATER HEATER.—*W. Matthews & J. & W. Yates, all of Manchester.*—This invention has for its object the heating of water by means of steam, and the apparatus consists of a calorifier or closed vessel, into which steam is admitted, the steam, or preferably the water, being within a coil, so that there is no actual contact between the steam and the water. From the calorifier the heated water passes into a circulating cylinder, which is also a closed vessel, and from thence into the reserve tank or cistern. The hot water may be withdrawn from the pipes leading from the calorifier to the circulating chamber, and the water resulting from condensation of the steam in the calorifier by gravity, or when this is impracticable by means of a steam trap. Claims: The apparatus for heating water, constructed and arranged substantially as described in the specification.—No. 10851. July 12th, 1890. 6*d.*

LOOMS.—*J. Thomis & M. & J. Priestley, all of Bradford.*—This invention has for its object the construction of a machine for operating the healds and warp threads in looms, in such a manner that when healds or warp threads have been raised, and the pattern surface requires the same to remain up for one or more picks of the shuttle, they are held in the raised position until liberated by mechanism connected with the pattern surface. The accompanying illustration represents in side elevation a heald operating machine suitable to the present combination of draw bars, one side of the machine being removed for the sake of clearness. On the frame A of the machine are mounted a series of draw bars equal to the number of healds required by the pattern; each set of draw bars is composed of three bars, two of which, B and C, are for operating the centre bar D, which is hinged to bar E, the said bar E being connected to the healds by a bell crank lever F. The reciprocating draw knives G H are operated by a rocking lever I and connecting rods, and an additional bar J is provided for holding the centre bars D and the healds in an elevated position. The draw bars B, C, and D are operated by three projections on the needles K, which in turn are operated by

a lever L and a rotating lag cylinder M. When the healds are down forming the bottom of the "shed" the bars C, D, and E are back towards the centre of the machine, and if the healds are to remain down, no peg on the lag cylinder M will present itself to the respective lever L, which will then be in the position shown in dotted lines, and the needle or needles K will be lifted so that the draw bars are clear of draw knives G H, and by this means the healds remain at the bottom of the "shed." When the pattern requires a change in the position of the healds, a peg on the lag cylinder will raise the respective lever L, allowing a corresponding needle K to descend, and one of the draw bars B or C to engage with a draw knife G or H, by which the draw bar and the centre bar D will be operated in such direction that the healds connected therewith are raised, the centre bar D engaging with stationary bar J; and if the healds are to remain up the centre bar D will remain engaged with the bar J for so many picks of the shuttle as there are pegs in the lag cylinder, keeping the lever L in the position shown in full lines. Claims: The combination of draw bars B and C with a retaining bar D, and operating needles K, arranged in the manner described.—No. 10980. July 14th, 1890. 8*d.*

Copies of the British specifications may be obtained on application to SIR HENRY READER LACK, *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*
